ATTITUDES TOWARDS MATERNAL VACCINATION IN PERU

Andrea Carcelen[1], Alba-Maria Ropero[2], Ines Gonzales-Casanova[3], Saad Omer[3]

[1]Johns Hopkins University, Baltimore, MD, United States, [2]Pan American Health Organization, Washington, DC, United States, [3]Emory University, Atlanta, GA, United States

The Peruvian national expanded program on immunization currently includes Tetanus-diptheria and influenza vaccination for pregnant women. Td coverage was reported as 56.1% for two or more doses in 2012, resulting in 82.1% of women's most recent births being covered against tetanus. Peru recommended influenza vaccination for pregnant women during the 2009-10 H1N1 vaccination campaigns, reaching only 9.1% of pregnant women. They have continued reporting providing seasonal influenza vaccine for pregnant women. Factors associated with maternal vaccination uptake are not well understood in Peru, but a 1995 missed opportunities study found that among 2,031 women of childbearing age, 47% had missed opportunities to vaccinate, most commonly for the first dose of tetanus toxoid. Reasons for missed opportunities included policy in the clinics, such as when to open a vial (31%), personal attitudes of women (30%), logistical challenges of the clinic (15%), false contraindications (20%), and attitude of health workers (4%). Given that 98.4% of women reported attending at least one prenatal care visit, the opportunity to vaccinate women is high. In order to better understand perception of vaccination during pregnancy, we will conduct in-depth interviews with 10 pregnant women. Adult pregnant women will be identified and recruited from a peri-urban community outside of Lima by community health workers. Sociodemographic data such as age, education level, religion, marital status and occupation will be collected. Women will also be scored with the Parent Attitudes About Childhood Vaccines (PACV) questionnaire to identify vaccine hesitant women. The in-depth interview guide includes knowledge of vaccines, antenatal care experience, comfort level discussing vaccination topics with healthcare personnel, information from peers about maternal vaccines, and motivating factors for vaccination. The results will be stratified by vaccine hesitancy according to the PACV. A preliminary codebook will be used, based on previous research in Latin America but will be updated as needed. Final results will be available August 2018.

COMMUNITY SUPPORT TO DELIVER INTEGRATED COMMUNITY CASE MANAGEMENT SERVICES IN NIGER STATE, NIGERIA

Ayodele Shola Alegbeleye[1], Olusola Oresanya[1], John Dada[1], Jonathan Jiya[1], Kolawole Maxwell[1], Patrick Gimba[2], Helen Counihan[3]

[1]Malaria Consortium, Abuja, Nigeria, [2]State Ministry of Health, Niger State, Nigeria, [3]Malaria Consortium, London, United Kingdom

Despite strong evidence showing integrated community case management (iCCM) as a proven intervention for reducing childhood mortality, sustainability remains a challenge. Community ownership and contribution are important factors in sustainability. The RAcE-funded iCCM project in Niger state (2014-2018) aimed at improving coverage of diagnostic, treatment, and referral services for malaria, pneumonia, and diarrhoea in children 2-59 months through trained community-oriented resource persons (CORPs). The project's community engagement strategy involved CORPs and social mobilizers (SMs) to increase community demand and support for iCCM services. SMs sensitized community members on appropriate health seeking behaviour and mobilized community engagement in iCCM. CORPs' needs were discussed in community dialogues, decisions taken to address them, and follow-up actions jointly implemented by community members, SMs and state iCCM team. SMs documented community support provided to CORPs in cash or kind and validated these during CORP review meetings. The value of the support

was estimated in US$ using current market rates and actual costs as appropriate. Over the project period, the value of all community support to CORPs was estimated at $122,786. Of this, 433 CORPs received cash assistance of about $18,131; 12 received community contributions for building their houses estimated at $12,376; 302 received chemicals and other farming support worth $67,790; while 301 received farm products and gifts. 47 CORPs received fuel or transport fare for drug collection from supervising health facilities totalling $1,437; five CORPs received motorcycles worth $984 and one a bicycle ($30). Best practices shared at local review meetings encouraged other communities to replicate achievements. Community contributions documented demonstrate the acceptability of iCCM in beneficiary communities and their willingness to contribute to ensure sustained services. Every community possesses unique resources to support iCCM implementation when explored through meaningful and transparent engagement.

TEACHING GLOBAL HEALTH COMPETENCIES TO MEDICAL STUDENTS THROUGH EXPERIENTIAL LEARNING WITH LOW-WAGE MIGRANT WORKERS IN SINGAPORE

Teem-Wing Yip[1], Calvin Ho[2], Victor Loh[2], Wei-Leong Goh[3], Jeffrey Chua[3]

[1]SingHealth, Singapore, Singapore, [2]National University of Singapore, Singapore, Singapore, [3]HealthServe, Singapore, Singapore

Global health competencies are recognised as an important, if not essential part of medical education, including cross-cultural skills, an understanding of migrant health, and primary health care in diverse settings, but not necessarily in an overseas context. This paper therefore reports on a novel global health education intervention spearheaded by the National University of Singapore School of Medicine, in partnership with HealthServe, a local non-governmental organisation that provides low cost healthcare services, casework and social assistance to migrant workers. While male low-wage migrant workers constitute 13% of Singapore's population, they have limited social contact with and are often poorly understood by the local population, and are often vulnerable due to limited medical, financial, legal and social support. The experiential learning occurs during the third year Family Medicine placement in a five-year undergraduate curriculum, where students interact with migrant workers in different settings over four evenings: at HealthServe's low-cost primary healthcare clinic, as guests at a migrant workers' dormitory, and informal social interactions in districts frequented by migrant workers in Singapore. The selective was designed to allow students to experience and reflect on the complexities of the psycho-social-cultural, political and global context of health and medicine within this vulnerable population. Over 500 reflective essays were collected between 2013 to 2018. In this paper, the results of a thematic analysis of these student reflections will be presented; emerging themes include students gaining more understanding and empathy for migrant workers' circumstances and disparate access to healthcare, gratitude for their own circumstances, and realising that they as privileged Singaporeans are not very different from low-wage migrant workers who come from other Asian countries to undertake the unpleasant work that Singaporeans don't wish to do. The analysis suggests that the learning experience resulted in the students' transformational learning and gaining of global health competencies.

805

REACHING THE HARD TO REACH: EARLY WARNING ALERT AND RESPONSE NETWORK AS A CRITICAL TOOL FOR REAL-TIME SURVEILLANCE DURING EMERGENCIES IN IRAQ

Mikiko Senga, Denise Assaf, Jawameer Kakakhan, Mohammed Al-Ghrairi, Kawa Salihi, Muhammad Khan, Manhal Alhalsa, Muntasir Elnoor, Altaf Musani

World Health Organization, Baghdad, Iraq

The early warning alert and response network (eWARN) is a surveillance system that was designed and tested in complex emergency settings. The main objective of eWARN is to rapidly detect and respond to signals that may suggest outbreaks and/or clusters of epidemic-prone diseases when other surveillance systems may be disrupted, overwhelmed, or unavailable. First established as a paper-based surveillance in Iraq in 2013, eWARN was upgraded using a real-time electronic tool in 2015 to accommodate a growing humanitarian crisis and an increasing vulnerability. This transformation process and supporting results give rise to a descriptive analysis using key indicator variables for eWARN's performance, including the number of continuously expanding reporting sites, alerts and consultations, with the goal of examining eWARN's effectiveness during the crisis in Iraq. In June 2015, the electronic version of eWARN had 90 reporting sites. This number grew to 214 by December 2017. While eWARN covered 11 out of 18 governorates in the country, Ninewa, Anbar and Dahuk had the highest number of consultations, reflecting the most severely affected areas by the emergency. In total, there were 8,995,097 consultations from health cluster partners between 2015 and 2017: 1,070,015 in 2015, 2,137,606 in 2016, and 5,787,476 in 2017. The top five reported diseases were acute upper respiratory infection, acute diarrhea, acute lower respiratory infection, skin diseases, and leishmaniasis. These diseases, which represented 41% of the total number of consultations, reflect common communicable diseases that affect refugees, internally displaced populations and hosting communities highlight the areas in need for prevention and control. While there are inherent limitations of the eWARN system, particularly reporting on selected diseases or symptoms, eWARN can prompt early detection of outbreaks, and, if used more long-term, the trends it provides can enhance preparedness. Taken these together, eWARN can contribute by rapidly detecting epidemic prone diseases with the aim of mitigating further transmission and ultimately reducing the burden of the disease.

806

A GENERALIZABLE APPROACH TO INCORPORATE LOCATION INFORMATION IN NETWORK RECONSTRUCTION AND OUTBREAK ANALYSIS FOR IMPROVED UNDERSTANDING OF THE SPATIAL ASPECTS OF TRANSMISSION RISK

Isobel E. Routledge[1], Kyle B. Gustafson[2], Nick W. Ruktanonchai[3], Azra C. Ghani[1], Samir Bhatt[1]

[1]Imperial College London, London, United Kingdom, [2]United States Department of the Navy, Washington, DC, United States, [3]University of Southampton, Southampton, United Kingdom

Increasingly disease surveillance data, collected routinely and as part of outbreak response, capture a wealth of information which could inform the design of epidemiological interventions. However challenges exist in making use of these diverse data sources. Robust methods to make the most of these data to are required in order best support decision making. Geographic information, in the form of GPS coordinates or address of residence and/or health facility, is often collected but could be more effectively utilised. Furthermore, the relative importance of location in determining observed patterns of infection and transmission risk compared to other factors such as age or occupation remains poorly understood for many diseases. It is unclear whether simple models of distance are sufficient to explain the variation observed and design effective interventions or whether more complex information and data e.g. realistic

models of human movement are required. Here we introduce a new, weighting based method which incorporates spatial or similar distance-based information into our previously developed methods to quantify spatiotemporal variation in transmission. We use these methods to quantify the relative contribution of location on the risk of one individual infecting another. We apply this method to line lists from a variety of diseases including measles, Ebola, malaria outbreaks in near elimination settings and H7N9 influenza as well as simulated outbreaks. We carry out model selection to explore various assumptions about the relationship between locations of cases and likelihood of transmission occurring between them including binary near/far thresholds, euclididan distance, power law and gaussian kernels, gravity models, and population flow models. We demonstrate the applicability of our approach to a variety of contexts and discuss results in relation to public health intervention design. Our approach also provides the potential to incorporate other sources of information which can be converted into distance matrices such as age or molecular markers.

807

TT SURGERY TRACKER - IMPROVING PATIENT CARE AS WE REACH ELIMINATION

Kimberly Jensen, Sarah Bartlett

Sightsavers, New Orleans, LA, United States

The global trachoma program has seen tremendous gains in the effort to eliminate blinding trachoma as a public health program, conducting over 230,000 trichiasis surgeries annually. With such gains comes the need to track not only the provision of the service, but the outcome of the surgeries provided. Few programs are conducting routine follow-up procedures in order to assess post-operative outcomes. Programs use templates from the International Coalition for Trachoma Control (ICTC) for consistent data collection, but the forms are paper-based, requiring lengthy processes to locate patient information and track patient outcomes. Due to these challenges, Sightsavers developed a mobile phone application to improve the systematic tracking of surgery provision in the global program. The android-based TT Surgery Tracker enhances timeliness and reporting of post-operative patient follow-up to improve quality of care. The tool documents surgeries conducted and the outcomes, by surgeon, to determine the need for additional training. It aims to increase follow-up completion through emailed reports to supervisors showing where and when follow-ups must take place. It also provides surgeons a monthly report, allowing them to assess their performance and providing encouragement for their efforts. Designated high-level workers can access up-to-date data online to view and download reports. Since November 2017, the application has been rolled out for testing in select districts in Nigeria and Tanzania. In total, 40 surgeons and recorders have been trained. To date, data have been collected on 896 and 517 surgeries and their subsequent follow-ups in Nigeria and Tanzania, respectively. Provisional results demonstrate that field teams are pleased with the Tracker's ease of use and benefits and Sightsavers is seeing positive results around improved efficiencies and program reporting - resulting in improved patient care. Once finalized in May 2018, the application will be provided to all country programs where enhanced trichiasis patient tracking is needed. It is anticipated that 10 country programs will be using the TT Tracker by the end of 2018.

808

AN AGENT-BASED MODEL OF EFFECTIVE COVERAGE OF APPROPRIATE MANAGEMENT OF CHILD ILLNESS

Emily D. Carter[1], Micky Ndhlovu[2], Thomas P. Eisele[3], Joanne Katz[1], Melinda K. Munos[1]

[1]Johns Hopkins School of Public Health, Baltimore, MD, United States, [2]Chainama College of Health Sciences, Lusaka, Zambia, [3]Center for Applied Malaria Research and Evaluation (CAMRE), Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States

Effective coverage of correct management of child illness is dependent on seeking care from a healthcare provider and receiving appropriate care from that provider. Agent-based modeling (ABM) is a potential means of modeling effective coverage using both household and healthcare provider data. ABM uses simple rules to model complex behaviors. In ABM, heterogeneous autonomous micro-entities or agents, act and interact with each other via defined rules. Agents make decisions or execute behaviors based on a defined set of rules. These micro-actions result in macro-level dynamics. We created and ran an ABM of care-seeking and management of child illness using NetLogo 6.0 and the NetLogo R extension. We parameterized the model using data from a household survey on care-seeking for 385 child illnesses and 83 healthcare provider assessments we conducted in Southern Province, Zambia in 2016. We collected data on 1) the timing and location of care-seeking for child illness, 2) potential determinants of care-seeking including illness, child, caregiver, and household characteristics, and 3) healthcare provider accessibility, cost, and structural quality to manage child illness. Sick children and providers were included in the model as agents dispersed over a geospatial plane. We used multilevel models to assess the relative effect of various factors on mothers' decisions to seek care. These values were used to parameterize care-seeking actions in our ABM. Once a child accessed care from a provider, they were assigned to have received correct or incorrect care with a probability derived from the provider's structural quality score. We estimated effective coverage as the total proportion of sick children that were correctly managed. We refined the model over multiple iterations. We assessed model performance by comparing the ABM effective coverage estimates to our empirical estimates of coverage. We modified model parameters to assess how coverage would change with alterations in care-seeking behavior and provider structural quality. ABM can be an effective means of modeling complex behaviors where adequate data for parameterization exists.

CLINEPIDB: THE CLINICAL EPIDEMIOLOGY DATABASE RESOURCE

Brianna Lindsay[1], Jessica Kissinger[2], Brian Brunk[1], Danica Helb[1], Sheena Shah-Simpson[1], David Roos[1], The EuPathDB Team[1]

[1]University of Pennsylvania, Philadelphia, PA, United States, [2]University of Georgia, Athens, GA, United States

Population-based epidemiological studies provide new opportunities for innovation and collaboration among researchers addressing pressing global-health concerns, however open access to study data pose many challenges. ClinEpiDB (https://clinepidb.org) is an open-access online resource enabling investigators to maximize the utility and reach of their data and to make optimal use of data released by others. ClinEpiDB was developed using the existing infrastructure of EuPathDB (https://eupathdb.org), a collection of databases covering 170+ eukaryotic pathogens, along with relevant free-living and non-pathogenic species and select pathogen hosts, which provides a sophisticated search strategy system enabling complex interrogations of underlying data. Currently, data integration for ClinEpiDB has occurred or is in process for NIH-supported International Centers for Excellence in Malaria Research (ICEMR), the Gates Foundation-supported Malnutrition and Enteric Diseases Network (MAL-ED), and the Global Enteric Multicenter Study (GEMS) projects. In the process of data integration, a unified semantic web framework has been used to describe data generated from these studies. The ICEMR projects used comprehensive surveillance data to elucidate interactions between malaria parasites, their mosquito vectors, and human hosts. The MAL-ED and GEMS projects studied the etiology, incidence and impact of childhood enteric disease in low-income countries. Over 1500 different data variables about participants, their associated anthropometry, demographics, and disease episodes were collected in these clinical epidemiology studies. Query results can be statistically analyzed and graphically visualized via interactive web applications launched directly in the ClinEpiDB browser,

providing insight into distributions and exploratory associations with any observational covariates. The ClinEpiDB resource will continue to grow with integration of new datasets, enhanced tool development and significant user outreach and education.

NOVEL METHODS FOR CONDUCTING A CENSUS TO DEFINE THE SAMPLING FRAME FOR A MALARIA HOUSEHOLD SURVEY IN ARTIBONITE, HAITI

Karen E. Hamre[1], Amber M. Dismer[1], Nishant Kishore[1], Kathleen McGee[2], Bernadette Fouché[1], Kathleen J. Holmes[1], Anyess R. Travers[1], Jean Frantz Lemoine[3], Michelle A. Chang[1]

[1]Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Population Services International, Peguy-ville, Haiti, [3]Ministère de la Santé Publique et de la Malaria, Port-au-Prince, Haiti

The Malaria Zero (MZ) consortium is working with the Ministry of Public Health and Population in Haiti to eliminate malaria by 2020. To inform the elimination strategy, a household survey was conducted in the communes of La Chapelle and Verrettes of Artibonite. In the absence of reliable census data to define an accurate sampling frame, we used novel methods to enumerate the population, monitor progress, and facilitate re-identification of the sampled households (HH) after selection. DigitalGlobe satellite images were imported into ESRI ArcGIS and overlayed with LandScan™ 1x1km grids that served as enumeration areas (EA). Images of all rooftops in the study area were digitized, and resulting maps used to develop the deployment plan for the enumerators. The maps were loaded onto tablets as geospatial PDFs with satellite and OpenStreetMap base layers to aid navigation. Enumerators captured GPS coordinates and details of each HH (e.g., inhabited, number living in HH, head of HH name), point of interest (POI; e.g., landmarks to assist in relocating a HH), and other digitized structures. Enumerators also talked with local guides and visited EA with no digitized structures to identify HH and POI that had been built since the date of the satellite images or to verify none existed. Data were collected on GSMA-enabled tablets for near real-time data synchronization using CommCare. Nightly, the coordinates of structures identified during the day were overlayed on those digitized using Quantum GIS to identify completed EA and areas of missed coverage. Each morning, these coverage maps were delivered to enumerators either on paper or via WhatsApp Messenger so they could return to the area if needed. Daily, coverage maps with cumulative numbers of HH, persons, and POI enumerated, and alerts on operational challenges (e.g., data connectivity, flooded roads) were sent to remote staff elsewhere in Haiti and the United States. In total, the census identified 33,060 households with an estimated population of 121,593 and 2,311 POI. The use of maps with digitized structures and daily coverage were novel methods that likely improved the quality of the population census.

811

THE FEASIBILITY OF CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS): GENERATING CONSTRUCTS, VARIABLES AND THEMES TO PRODUCE CREDIBILITY IN QUALITATIVE RESEARCH

Elizabeth O'Mara Sage

Centers for Disease Control and Prevention, Decatur, GA, United States

CHAMPS aims to address childhood mortality by generating reliable data on the causes of death for children under 5. This process is complex as data are derived from various sources, including laboratory findings from minimally invasive tissue sampling (MITS) conducted on the body of a deceased child. The sensitive nature of this procedure inevitably evokes religious, cultural, and ethical questions that influence the feasibility of CHAMPS. Due to limited behavioral studies and theoretically sound paradigms related to child MITS, we developed an innovative qualitative methodology to determine the barriers, facilitators and other factors that affect the implementation and sustainability of CHAMPS surveillance across 7 diverse sites. We employed a multi-method grounded theory approach and analytical structure based on culturally specific frameworks comprised of focused constructs and variables. These frameworks provided direction for in-depth interviews, focus groups and observations needed to maximize the credibility of CHAMPS feasibility. The frameworks also guided data interpretation and collective analyses confirming how to articulate and define dimensions of CHAMPS feasibility within the cultural context of each site. Findings showed that the approach to MITS consent and procedure involve incorporating religious factors associated with timing of burial, use of certain consent terminology and methods of transporting the body. Community misperceptions and uncertainties of CHAMPS resulted in a need for rumor surveillance and consistency in information sharing. Other findings indicated that religious pronouncements, recognition of health priorities, attention to pregnancy and advancement of child health facilitates community acceptability. These findings helped form program priorities, site-specific adaptations in surveillance procedures, and verified the integrity of inferences drawn from diverse epidemiological and social data. Results informed appropriate community sensitization and engagement activities for introducing and sustaining mortality surveillance including MITS.

812

SPATIAL PATTERNS OF WATER STORAGE PRACTICES AND UPTAKE OF VECTOR CONTROL BEHAVIORS FOR ZIKA TO IMPROVE PREDICTIVE MAPPING OF *AEDES AEGYPTI* IN CENTRAL AMERICA

Jessie Pinchoff[1], Martha Silva[2], Jeni Stolow[2], Paul Hewett[3], Lina M. Moses[2]

[1]Population Council, New York, NY, United States, [2]Tulane University, New Orleans, LA, United States, [3]Population Council, Washington DC, United States

In 2015-2016 there was an outbreak of Zika virus throughout central and South America, a region where previously no cases had been recorded. This outbreak was associated with increased incidence of microcephaly and Guillain-Barre Syndrome; in one year it infected over 500,000 people (suspected and confirmed cases) in 40 countries and territories in the Americas. Zika virus is transmitted by *Aedes aegypti*, which is also the primary vector for Dengue, Chikungunya and Yellow Fever, diseases considered endemic to the region. *Ae. aegypti* has flourished in urban landscapes, where human-driven activities have created more suitable environments for larval development. While GIS data and maps have been used to create epidemiological maps to guide programmatic targeting of vector control activities, this has been challenging for Aedes-borne diseases, with entomological maps failing to align with human infection risk. We propose inclusion of human behavior to improve the precision of these predictive maps. A cross-sectional household survey will be implemented between April and June 2018 in the Dominican Republic, Honduras, Guatemala and El Salvador (n=600 per country). GPS points will be recorded for each household, to explore the spatial patterns of knowledge, attitudes and practices related to vector control behaviors. Using satellite imagery and remotely sensed data, environmental data previously reported to be associated with *Ae. aegypti* abundance will be overlaid on the survey data; bare soil coverage percentage, urbanization coverage percentage, water distribution, weekly rainfall and population density. These data will be used to explore spatial variation in vector abundance using available sentinel entomological data, and to explore linkages with household water storage practices and prevention behaviors. We hypothesize that incorporation of household adoption of recommended vector control behaviors will improve the fit of models, when compared to environmental factors alone.

813

PREDICTING TICKBORNE INFECTIONS AND COINFECTIONS WITH DIAGNOSTIC DECISION TREES

James H. Diaz

Louisiana State University Health Sciences Center, New Orleans, LA, United States

Tick-transmitted infections and coinfections with emerging pathogens are increasing in the United States (US) and complicating diagnosis and treatment. To identify the most common tickborne infections and coinfections and their vectors in the US and to design a decision tree approach to the diagnosis of tickborne infections, Internet search engines were queried with key words to select scientific articles on tickborne infections and coinfections over the reporting period, 2000-2018. Key words included ticks, emerging and reemerging tickborne infections and coinfections. Molecular studies of pathogen coinfection seroprevalence rates in ticks and animal reservoir hosts have confirmed that pathogen infections and coinfections with *Borrelia burgdorferi*, *Babesia microti*, *Anaplasma phagocytophilum*, *Ehrlichia chaffeensis*, and *E. ewingii* do occur in regional zoonoses and that nymph and adult ticks that feed on multiple infected animal hosts can transmit these pathogens concurrently to humans during blood-feeding. Among the ten tick species capable of transmitting coinfections, the four tick species that have transmitted regional coinfections in the US include: (1) *Amblyomma americanum* in the East & Southeast; (2) *Dermacentor andersoni* in the Appalachians & Midwest; (3) *Ixodes pacificus* along the Pacific Coast; and (4) *Ixodes scapularis* in the Northeast and Upper Midwest. Mathematically solving diagnostic decision tree models that account for prior regionally confirmed human cases and current pathogen seroprevalence rates in ticks and their reservoirs will assist clinicians in predicting and diagnosing tickborne infections and coinfections and guiding appropriate antimicrobial therapy. Clinicians should suspect tickborne coinfections in returning travelers and vacationers with clinical and serological evidence of multiple infecting agents, especially in cases of unusual presentation or severity, prolonged duration, or non-response to single antibiotic therapy, typically with doxycycline.

814

UNUSUAL PRESENTATIONS OF BABESIOSIS WITH DELAYED DIAGNOSIS IN THREE PATIENTS WITH INTACT SPLEENS AND MIXED INFECTIONS

Don W. Kannangara[1], Renu Toshniwal[1], Saman Kannangara[2], Hoda Samia[1], Pritiben Patel[1], Sidra Sindhu[1]

[1]St Luke's University Health Network, Phillipsburg, NJ, United States, [2]Easton Hospital, Easton, PA, United States

Babesiosis is an anthropo-zoonotic tick-borne disease of vertebrates. Of more than 100 known species, only *Babesia microti*, *B divergens, B duncani* and *B venatorum* have been reported in humans. The intra-erythrocytic parasite causes an infection that ranges from asymptomatic to life threatening . More severe and fatal cases have been in asplenic or immunocompromised individuals. some cases have been transmitted by blood transfusion. Here we report 3 unusual presentations, where 2 were initially misdiagnosed as pyelonephritis, and the other accidentally discovered during treatment of neuroborreliosis. One presented with fever for 2 weeks and left flank pain, treated at an urgent care center with macrobid for a urinary infection. She had leukopenia, thrombocytopenia and abnormal liver functions. On therapy with Ceftriaxone and doxycycline she developed a Jarisch-Herxheimer reaction (JH) with high fever and a new rash. *Babesia* smear and PCR was positive for *B microti*. The second patient admitted with left flank pain and fever for 1 week was treated with Levofloxacin. The admission diagnosis was pyelonephritis. Fever worsened and patient had multiple antibiotic changes, with no response. Finally a blood smear was positive with positive antibody test for *B microti*. She gave a history of Lyme Disease. Both responded to atovoquone and azithromycin (A&A). The third patient, while on therapy for neuroborreliosis with ceftriaxone developed fever, thrombocytopenia and anemia. She was empirically started on (A&A). The fever, thrombocytopenia and anemia resolved. Splenomegaly, Splenic rupture and splenic inflammation have been reported in babesiosis. But we are not aware of any misdiagnosed as pyelonephritis. Source of the left abdominal discomfort was the spleen. JH is known occur during therapy of Spirochetal infections such as *Borrelia*, *Treponema* and *Leptospira*. We believe JH was due to a mixed infection. *B burgdorferi* and *B miyamotoi* have been reported in *Ixodes scapularis* in the area. Lyme Western Blot was negative. In areas with heavy tick infestation, clinicians have to be vigilant to avoid misdiagnosis of tick-borne infections.

815

PCR OF WHOLE BLOOD COMPLEMENTS SEROLOGY FOR CONFIRMATION OF EARLY LYME DISEASE AND ALLOWS FOR CONFIRMING A DIAGNOSIS IN 10% OF ACUTE PATIENTS WITHIN A NEGATIVE ANTIBODY WINDOW PERIOD

Philip Molloy[1], Katie Pomerantz[2], Wolfgang Pieken[2], Sam R. Telford III[3]

[1]Imugen (Division of Oxford Immunotec, Inc), Norwood, MA, United States, [2]Oxford Immunotec, Marlborough, MA, United States, [3]Tufts University, N. Grafton, MA, United States

Early Lyme disease is a clinical diagnosis when a patient presents with typical erythema migrans. However, atypical dermal lesions or febrile illness without erythema migrans requires laboratory testing to establish a diagnosis of Lyme disease. Such testing usually comprises serology, preferably of acute and convalescent samples. Directly detecting *Borrelia burgdorferi*, the agent of Lyme disease, has historically been impractical due to the need for invasive skin biopsies from which it may be cultured, and because of the low numbers of organisms in routine clinical specimens. *B. burgdorferi*, however, may be cultured from large volumes of whole blood sampled from early Lyme disease patients. It may be that more recent protocols for extracting larger volumes of blood for DNA and the use of sensitive real time PCR assays may also detect hematogenous *B. burgdorferi* from early Lyme disease patients. Accordingly, we analyzed 21,433 unique acute patient specimens submitted for Lyme diagnostic testing during 2016, focusing on those for which both serology and PCR testing had been requested. Real time PCR was performed using a pan-*Borrelia* primer set and any positive reanalyzed specifically for evidence of *B. burgdorferi* or *B. miyamotoi*. Of these, 1569 (7.3%) had laboratory results consistent with early Lyme disease. The majority (83.5%) of these 1569 samples were considered reactive in an IgM capture EIA with confirmation by immunoblot but were PCR negative. Another 5% were concurrently IgM positive and PCR positive. Interestingly, 11.5% were considered seronegative but PCR positive. We conclude that complementing serology with PCR incrementally improves the confirmation of a diagnosis of early Lyme disease, particularly for those patients within a window period when antibody may not yet be detectable.

816

CLIMATE CHANGE INFLUENCES ON THE POTENTIAL GEOGRAPHIC DISTRIBUTION OF THE DISEASE VECTOR TICK *IXODES RICINUS*

Abdelghafar A. Alkishe[1], A. Townsend Peterson[1], Abdallah M. Samy[2]

[1]Biodiversity Institute, University of Kansas, Lawrence, KS, United States, [2]Entomology department, Faculty of science, Ain Shams University, Cario, Egypt

Ixodes ricinus is a species of hard tick that transmits several important diseases in Europe and North Africa, including Lyme borreliosis and tick-borne encephalitis. Here, we assessed the potential distribution of *I. ricinus* under current and future climate conditions to understand how

climate change will influence the geographic distribution of this important tick vector and associated tick-borne pathogens in coming decades. We used ecological niche modeling to estimate the geographic distribution of *I. ricinus* with respect to current climate, and then assessed its future potential distribution under different climate change scenarios. This approach integrates occurrence records of *I. ricinus* with six relevant environmental variables over a continental extent that includes Europe, North Africa, and the Middle East. Future projections were based on climate data from 17 general circulation models (GCMs) under 2 representative concentration pathway emissions scenarios (RCPs), for the years 2050 and 2070. The results show that the present and future potential distributions of *I. ricinus* showed broad overlap across most of western and central Europe, and in more narrow zones in eastern and northern Europe, and North Africa. Potential expansions were observed in northern and Eastern Europe. These results indicate that *I. ricinus* populations could emerge in areas in which they are currently lacking, posing increased risks to human health in those areas.

817

MODELING ENVIRONMENTAL DRIVERS OF HOST-SEEKING BEHAVIORS THAT AFFECT BLACKLEGGED TICK HOST-FINDING SUCCESS

Max McClure[1], Danielle Tufts[1], María Fernández[1], Jean Tsao[2], Graham J. Hickling[3], Maria Diuk-Wasser[1]

[1]Columbia University, New York, NY, United States, [2]Michigan State University, East Lansing, MI, United States, [3]University of Tennessee Knoxville, Knoxville, TN, United States

The blacklegged tick (*Ixodes scapularis*) is the primary vector of *Borrelia burgdorferi*, the causative agent of Lyme disease in the US. The basic reproduction number (R_0) for pathogens transmitted by this tick is highly sensitive to the probability of larvae molting into nymphs and subsequently contacting a host. Incorporating regional variation in nymph host-finding success into models will allow for more accurate prediction of tick-borne pathogen persistence or decline. Here we present a novel approach to evaluating the relationship between host-finding success and host abundance that combines field data with a dynamic state variable model of tick questing behavior. Mark-recapture density estimates for the primary host, the white-footed mouse (*Peromyscus leucopus*) and on-host larval and nymphal densities from live-trapped mice, were obtained in 2015 and 2016 in mainland Connecticut and on Block Island, Rhode Island, with higher densities estimated at the island site. Tick overwinter survival - estimated from ticks enclosed in tubes - was >50% and did not differ significantly between sites. Ambient and leaf litter relative humidity (RH) were collected via HOBO weather stations and iButton data loggers during the questing season. Mean RH over this period varied significantly between sites (mainland air: 78.4%; mainland litter: 90.1%; island air: 90.2%; island litter: 91.6%). Using these data as dynamic state variable model inputs, we predicted host-finding success. Model predictions were then compared to host-finding success estimates for the two locations obtained by calculating the ratio of on-host nymph density to on-host larva density at the same site the preceding year, taking into account overwinter survival. Differences between the two sets of estimates were used to reparametrize the relationship between host population density and the probability of encountering a host while questing, which is a key function in our model. Informing the dynamic state variable model with field data served as an initial step towards disentangling the roles played by climate and host availability in determining tick host-finding success.

818

HIGH SENSITIVITY DETECTION OF MULTIPLE TICK-BORNE INFECTIONS IN BLOOD AND URINE USING NANOPARTICLE ENTRAPMENT AND MASS SPECTROMETRY

Robert E. Molestina[1], Ruben Magni[2], Alessandra Luchini[2], Lance Liotta[2]

[1]ATCC, Manassas, VA, United States, [2]George Mason University, Manassas, VA, United States

Tick-borne diseases (TBD) among humans are on the rise in North America. As ticks may be co-infected with several pathogens, there is a high likelihood of co-transmission of Lyme disease, babesiosis, and other TBDs to humans, thus affecting disease severity. To date, there are no FDA-approved assays for mass screening of TBDs. To address this need, our group uses a new class of biomarker harvesting nanocage technology, which, when combined with mass spectrometry (MS) can determine the presence of pathogen proteins shed in bodily fluids of mammalian hosts. Using the hamster model of babesiosis, our nanoparticle-MS approach identified several *B. microti* proteins in blood, serum, and urine. Surface and secreted antigens previously shown to elicit host immune responses against the parasite were particularly abundant compared to other proteins. Confirmation of expression of three of these antigens was shown in the cytoplasm and/or surface of infected hamster erythrocytes by immunological assays. Of note, urine samples from acutely infected animals harbored parasite proteins with housekeeping functions. Interestingly, the presence of urinary proteins was not exclusive to the experimental hamster model, as MS analysis of urine samples from human patients with TBD also revealed the presence of babesial proteins. Moreover, a subset of patients showed evidence of multiple co-infections, as peptides deriving from tick borne pathogens such as *Borrelia burgdorferi*, *Ehrlichia* sp., *Rickettsia* sp., *Anaplasma phagocytophilum*, and *Francisella tularensis* were also detected in urine. In summary, using a novel nanoparticle-MS approach, we have achieved a high level of analytical sensitivity necessary to detect multiple TBDs in blood and urine. This was previously difficult to achieve due to the low abundance of microbial markers concealed by the complex biomolecular matrix of bodily fluids from the host. Further adaptation of this technology into high throughput testing and/or immunochromatographic tests can provide a platform for a one-step, rapid analysis of multiple tick borne infections for use in screening, transmission control, and treatment.

THE *BABESIA* OBSERVATIONAL ANTIBODY (BAOBAB) STUDY: SURVEILLANCE FOR *BABESIA MICROTI* IN KILOSA DISTRICT, TANZANIA

Evan M. Bloch[1], Jerusha Weaver[2], Zakayo Mrango[3], Mabula Kasubi[4], Aleksandra Mihailovic[2], Beatriz Munoz[2], Kurt Dreger[2], Anna Weimer[5], Giovanna Carpi[6], Douglas Norris[6], Andrew Levin[7], Laura Tonnetti[8], Jeffrey M. Linnen[9], Vanessa Bres[9], Sheila K. West[2]

[1]Johns Hopkins University School of Medicine, Department of Pathology, Baltimore, MD, United States, [2]Johns Hopkins University School of Medicine, Dana Center for Preventive Ophthalmology, Baltimore, MD, United States, [3]National Institute for Medical Research, Kilosa, United Republic of Tanzania, [4]Muhimbili University of Health and Allied Sciences, Department of Microbiology, Dar es Salaam, United Republic of Tanzania, [5]Johns Hopkins University School of Medicine, Baltimore, MD, United States, [6]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [7]Kephera Diagnostics, LLC, Wellesley, MA, United States, [8]American Red Cross, Rockville, MD, United States, [9]Grifols Diagnostic Solutions, Inc, San Diego, CA, United States

Babesia is a genus of tick-borne intraerythrocytic protozoan parasites. Most human *Babesia* infections, ascribed to *B. microti*, are subclinical or mild, yet severe and fatal complications are well described. *Babesia* is globally ubiquitous yet human surveillance is lacking, particularly in Africa.

Findings from a pilot *B. microti* serosurvey in Kilosa district, Tanzania, suggested that *Babesia* may be present. In follow-up, a cross-sectional study was conducted July-August 2017: residents in a case hamlet that had clustering of subjects with high signal-to-cut off (S/CO) ratios for antibodies against *B. microti* in the pilot study, and a control hamlet that had lacked significant signal, were evaluated for *B. microti*. In addition to clinical evaluation and household inspections, subjects aged ≥15yrs (n=299) had 10ml whole blood drawn for evaluation by transcription mediated amplification (TMA) for *B. microti, B. divergens, B. venatorum* and *B. duncani*; *B. microti* indirect fluorescent antibody testing and rapid diagnostic testing (RDT) for *Plasmodium* spp. Those aged <15yrs (n=266) underwent RDT for *Plasmodium* and serological assessment with a *B. microti* ELISA. A total of 570 subjects participated (mean age 22 [<1 to 90yrs]) of whom 50.7% were female; 145 (25.5%) subjects were *Plasmodium* RDT positive (+). In those <15yrs, the median ELISA S/CO was 1.11 (IQR 0.80-1.50); the median S/CO in the case (n=121) and control (n=146) hamlets were 1.19 (IQR 0.81-1.48) and 1.06 (IQR 0.80-1.50) respectively (p=0.3). Children ≥5yrs old were more likely to have a higher S/CO ratio than those <5yrs old (p<0.001). Ninety-nine (37%) subjects <15yrs were *Plasmodium* RDT+. The median S/CO ratio (children <15yrs) did not differ by RDT status (p=0.18). In subjects ≥15yrs, no molecular positivity was detected for *Babesia*; four subjects were IFA reactive (two each at titers of 128 and 256). While an increase in *B. microti* seroreactivity with age is in keeping with true positivity, random distribution of *B. microti* seroreactivity in both the case and control hamlets raises concerns of cross-reactivity (e.g. *Plasmodium*, non-zoonotic *Babesia* spp.) or non-specificity.

820

THE TICK APP: A SMARTPHONE APPLICATION TO ASSESS HUMAN BEHAVIORAL RISK FACTORS OF HUMAN-TICK CONTACTS

Maria Pilar Fernandez[1], Gebienna M. Bron[2], Scott R. Larson[2], Pallavi A. Kache[1], Lyric C. Bartholomay[2], Jean I. Tsao[3], Susan M. Paskewitz[2], Maria A. Diuk-Wasser[1]

[1]Columbia University, New York City, NY, United States, [2]University of Wisconsin - Madison, Madison, WI, United States, [3]Michigan State University, East Lansing, MI, United States

Zoonotic diseases occur at the interface of human and ecosystem health. However, the lack of sufficient knowledge on the complex interactions between humans and the natural world has been a major barrier to the effective implementation of sustained disease control methods, with multiple examples across vector-borne disease systems. In the case of Lyme disease, individual human exposure will depend on the density of infected ticks (entomological risk) as well as on human activity and movement patterns affecting their exposure risk. As part of a broader project on the coupled natural and human dynamics of tick-borne diseases, here we report on the implementation of a smartphone application, The Tick App, as a survey tool to collect high spatial and temporal resolution data on human behaviors and movements associated with tick exposure. This app also aims to raise awareness among the general public by engaging users in tick identification and reporting. The ubiquity of smartphones allows for the potential to reach a large section of the population in a more cost-effective manner than most traditional epidemiological surveys. Traditional mechanisms of data collection (e.g., retrospective questionnaires) are subject to recall bias and do not capture specifics in intra-subject variability, particularly when participants are required to generalize an experience or behavior. The Tick App addresses this issue by allowing for real-time reporting. During the summer of 2017, 11 people piloted the app on Block Island, RI, with an average of 56 active sampling days. Based on this experience, a subsequent version of the app was made available to the public during the spring and summer of 2018 in the U.S. midwestern and northeastern regions. Its implementation was monitored closely in two areas within both regions across a gradient of endemicity, human demography and urbanization. Incorporating behavioral and movement data into empirically-informed tick-borne disease models will provide insights into the relative importance of factors driven by humans and nature, their interactions, and potential targets for intervention strategies.

821

MODELING LYME DISEASE SYMPTOMATOLOGY IN ASSOCIATION WITH TICK-BORNE PATHOGEN CO-INFECTIONS IN HUNTING DOGS IN THE UNITED STATES

Kurayi Mahachi, Angela J. Toepp, Breanna M. Scorza, Christine Petersen

University of Iowa, Iowa City, IA, United States

In North America, infection with the spirochetal bacterium, Borrelia burgdorferi, transmitted by Ixodes scapularis and Ixodes pacificus ticks, is the primary cause of Lyme disease in humans and dogs. Moreover, Ixodes spp. are known to transmit other pathogens and there is a high potential for co-infection with multiple tick-borne diseases. However, the subsequent effects on symptom severity are not well described in the literature. Thus, by modeling both co-infection rates and Lyme disease severity, classified by the number of lyme positive symptoms, this project aims to shed light on the interplay between pathogens in a co-infected canine host. Blood samples collected from a cohort of approximately 650 hunting dogs around the United States were analyzed for B. burgdorferi, Anaplasma spp., Ehrlichia spp., and Babesia using qPCR and ELISA to detect presence or absence of tick-borne pathogen DNA or antibodies, respectively. Clinical signs of Lyme disease were also recorded and canine disease status was classified into 3 categories: Asymptomatic, classified by a positive Polymerase chain reaction (PCR) or serologic result (ELISA) and less than 2 lyme signs. Symptomatic, classified by a positive PCR or ELISA result and 2 or more lyme signs, or Negative, classified by a negative PCR and ELISA result. Co-infection and exposure rates were calculated using statistical analysis, following this, lyme symptomatic data was correlated with co-infecting tick-borne pathogens. Moreover, this data was then used to develop a regression model with lyme symptomatic as an outcome, that would assess relative risk associated with tick-borne disease co-infection By better identifying host-pathogen interactions in dogs, this study hopes to provide information regarding how Lyme disease may manifest in other co-infected hosts, such as humans. Therefore, providing information that may improve our ability to diagnose and treat Lyme disease.

822

A DUO 4-PLEX REAL TIME PCR FOR DETECTION OF EIGHT TICK BORNE ZOONOSES IN KENYA

Beth K. Mutai[1], John N. Waitumbi[1], Humphrey Njaanake[2], Benson B. Estambale[2]

[1]Kenya Medical Research Institute / Medical Research Directorate - Kenya, Kisumu, Kenya, [2]Department of Medical Microbiology, University of Nairobi Kenya, Nairobi, Kenya

Ticks can harbor multiple pathogens which they may transfer to humans. The ensuing zoonoses display non specific symptoms that make definitive diagnosis difficult. We report here the development and evaluation of multiplex qPCR assays for eight tick borne zoonoses (TBZ). The assays were organized in duo formats of 4-plex each. Format 1 was optimized for *Anaplasma phagocytophilum*, *Coxiella burnetii, Borrelia burgdoferi and Ehrlichia chaffeensis.* Format 2 was optimized for *Rickettsia spp*, *Bartonella spp*, *Borrelia spp* other than *B. burgdoferi* and *Babesia spp*. using synthetic plasmids; we show that the assays can specifically detect all the target sequences in the same reaction tube. Assay 1 had a limit of detection of 1gene copy for all targets. Assay 2 was less sensitive and on average had a limit of detection of 18 gene copies. In replicate tests, both assays had intra-assay variation of less than two cycles. Evaluation of 512 clinical samples collected from AFI patients attending hospitals in different counties revealed a 20 % prevalence of tick borne pathogens comprising *B. burgdoferi* (7 %), non *B. burgdoferi Borrelia spp* (4 %), *C. burnetii* (5 %), *A. phagocytophilum* (6 %), *Rickettsia* (2 %), *E. chaffeensis* (0.8

%), *Bartonella spp* (0.8%), and *Babesia spp* (0.4 %). The high analytical sensitivity suggests potential for the duo 4-plex qPCR for detection of common TBZ.

823

APPLICATION OF WHOLE GENOME SEQUENCING TO STUDY THE GENETIC DIVERSITY OF FIELD COLLECTED *ORNITHODORUS* TICKS AND THE PATHOGENS THEY CARRY FROM NIGERIA

Nusirat Elelu[1], Jibrin M. Idris[2], Akeem O. Ahmed[1], Sally J. Cutler[3]

[1]University of Ilorin, Ilorin, Nigeria, [2]African Field Epidemiology Network, Abuja, Nigeria, [3]University of East London, Stratford, London, United Kingdom

Ornithodorus ticks are established vectors of relapsing fever in humans caused by *Borrelia* species and have also been reported to be potential vector for the recently emerging Alkhurma haemorrhagic fever virus. They have been reported from various parts of the world. However, there are not much genomic data utilizing sensitive techniques from Africa. Whole Genome Sequencing (WGS) using MinION (Oxford Nanopore), is a new and rapid third generation sequencing technology that has been successfully utilized to determine species of mosquito vectors and detect a variety of vector borne viruses. Using qPCR and WGS, we attempt to determine the species of *Ornithodorus* ticks and the pathogen they carry from a semi-arid Northeastern Nigeria. The sequence data generated was used to infer phylogenetic relationships among ticks as well as the pathogens detected. Genomic DNA was extracted from field collected ticks pooled by life stages. PCR analysis to identify tick species using primers against tick 16S gene and Sanger sequencing of resulting amplicons was initially carried out. The preliminary results by qPCR revealed the species of ticks to be *Ornithodoros savignyi.* Samples were further screened for the presence of *Borrelia* by sequencing of 16S, flagellin and IGS regions which revealed the presence of *Candidatus* Borrelia kalaharica. A recently proposed species that caused relapsing fever in a returning traveller from Southern Africa to Germany. The complete results from more extensive field sampling and analyses from sequence generated from the MinION will be presented at the meeting. This is the first report of relapsing fever *Borrelia* of public health importance from Nigeria. Furthermore, genomic data generated could help in better understanding of the diversity of tick species and for improved vector-borne disease diagnostics.

824

SYNANTHROPIC RODENTS AS CARRIERS OF IMPORTANT ZOONOTIC PATHOGENS - FIRST REPORT FROM BHUTAN

Yoenten Phuentshok[1], Kezang Dorji[2], Tandin Zangpo[2], Silas A. Davidson[3], Ratree Takhampunya[3], Tenzinla Tenzinla[1], Chencho Dorjee[4], Peter Jolly[5], Roger Morris[5], Sithar Dorjee[4], Joanna McKenzie[5]

[1]National Centre for Animal Health, Serbithang: Thimphu, Bhutan, [2]Department of Public Health, Ministry of Health, Thimphu, Bhutan, [3]Entomology Department, Armed Forces Research Institute of Medical Sciences (AFRIMS), Bangkok, Thailand, [4]Khesar Gyalpo University of Medical Sciences of Bhutan, Thimphu, Bhutan, [5]International Development Group, Institute of Veterinary Animal and Biomedical Sciences, Massey University, Palmerston North, New Zealand

The number of acute undifferentiated febrile illness cases (AUFI) has been on the rise recently in Bhutan leading to misdiagnosis and inadequate treatment. Bhutan is a small country known for its rich biodiversity and strong conservation policies. It has approximately 80 rodent species. Rodents are well known reservoirs and vectors of many emerging and re-emerging infectious diseases, but little is known about their potential role in zoonotic disease transmission in Bhutan. A cross-sectional study of zoonotic disease pathogens in rodents was performed in Chukha district, Bhutan where many AUFI cases have been detected in people. Field collections were performed in 2016 and 2017. Rodents in and around houses and agricultural fields were trapped using live wire mesh traps. Following euthanasia, liver and kidney tissues were removed and tested by Polymerase Chain Reaction (PCR) for *O. tsutsugamushi* and other bacterial and rickettsial pathogens causing Bartonellosis, Borreliosis, human monocytic ehrlichiosis (HME), human granulocytic anaplasmosis (HGA), leptospirosis, and rickettsiosis. A phylogenetic analysis was performed on all rodent species captured and pathogens detected. Four out of the twelve rodents (33%) sampled in 2016 tested positive by PCR for a zoonotic pathogen. *Anaplasma phagocytophilum*, *Bartonella grahamii*, and *B. queenslandensis* were identified for the first time in Bhutan. *Leptospira interrogans* was also detected for the first time from rodents in Bhutan. Twenty-four additional rodents were collected in 2017, the results from these samples are still being analyzed and the final results will be presented during the meeting. Our study shows that sampling even a few rodents in Bhutan can provide important information about potential risks of rodent-borne zoonotic diseases. This is first of this kind of study conducted in Bhutan and more studies are warranted with a larger sample size and that cover more localities and diverse landscapes. We expect interesting findings from rodents sampled in 2017 and ongoing studies. This data will be used to better quantify the risk of rodent-borne zoonotic diseases in Bhutan.

825

INCIDENCE OF HUMAN MONOCYTIC EHRLICHIOSIS IN SITES WHERE LONE STAR TICK INFESTATIONS HAVE RECENTLY EMERGED

Sam R. Telford III[1], Katie Pomerantz[2], Wolfgang Pieken[2], Philip Molloy[2]

[1]Tufts University, N. Grafton, MA, United States, [2]Oxford Immunotec, Inc., Marlborough, MA, United States

The Lone Star tick (*Amblyomma americanum*), has greatly expanded its distribution in the northeastern United States within the last decade. Once largely restricted to western Long Island and New Jersey south to Florida and westward to Texas, sporadic specimens have now been recorded from all northeastern states, and focal perpetuating infestations have been identified in Massachusetts. This aggressively human biting tick is a known vector for STARI/Masters Disease, human monocytic ehrlichiosis (HME), *Ehrlichia ewingii* ehrlichiosis, Rocky Mountain spotted fever, and tularemia; a common symbiont of Lone Star ticks, *Rickettsia amblyommatis*, is suspected of causing febrile illness in people. The public health burden of new Lone Star tick infestations has not been determined. We analyzed 37,133 blood samples submitted by clinical practices in CT, MA, RI, ME, NH, and VT during 2016-2017 for evidence of *Ehrlichia chaffeensis* (the agent of HME) DNA by polymerase chain reaction. By comparison, 21,082 blood samples were similarly analyzed from NJ, NY, PA, and MD, where Lone Star ticks have been endemic for at least two decades. Only two samples (0.005%) were positive from the New England sites whereas 0.63% of those from sites farther south were positive. We conclude that risk of acquiring HME and likely that of the other less common zoonotic infections transmitted by Lone Star ticks is very small in sites where they have recently invaded.

826

RISK OF TICK-BORNE ENCEPHALITIS VIRUS INFECTION IN NORTHERN KAZAKHSTAN

Zhanna Shapiyeva[1], T. Nurmakhanov[1], Y. Sansyzbayev[1], L. Ziyadina[1], S. Tastanova[1], Iain Hay[2]

[1]SPCSEEM, Almaty, Kazakhstan, [2]State University of New York at Buffalo School of Medicine, Buffalo, NY, United States

Tick-borne encephalitis (TBE) is becoming a growing public health problem in Kazakhstan. Recognized areas of spread of this infection are the eastern and south-eastern regions. At the same time, in recent years, there have been registered cases of TBE infection in the northern region of the republic, in particular in the Akmola region (24 cases in the period

of 2010 - 2017). The purpose of our research was to determine the tick species circulating in the northern region for the presence of TBEV. A total of 2,036 tick samples were collected in the territories of three oblasts of Northern Kazakhstan (Akmola, North Kazakhstan, Kostanay), divided into 257 pools according to species, gender, and collection location, and prepared for research. The species composition of ticks was represented mainly by *D. marginatus* and *D. pictus*, and to a lesser extent *Ix.persulcatus*. Homogenized tick pools were tested in parallel, using ELISA and PCR methods to compare and determine their viral load. All results were negative with ELISA. Using RT-PCR assays, the RNA of TBE virus was detected in 24 samples (9.3%). The highest rate of positive results was for the North Kazakhstan (15%) and Akmola (9.7%) oblasts. The tick species composition for positives was *D. marginatus* (62.5%), *D. pictus* (33.4%), and *Ix.persulcatus* (4.1%). The results of the tests show that the TBEV vectors are not only represented by *Ix. persulcatus* - the predominant vector in many parts of the world, but also with ticks of the *Dermacentor* genus (*D.marginatus* and *D.pictus*). This fact significantly increases the risk of infection for the population living in northern Kazakhstan and requires implementation of prevention and control. For the first time TBEV was isolated from ticks in the Kostanay oblast. In addition, it was confirmed that the sensitivity and specificity of the PCR method for TBEV determining is higher than that of antigen capture ELISA. In order to better understand the geographic distribution of infected ticks within Kazakhstan, it is necessary to have further long-term epidemiologic and entomologic TBEV studies.

827

SUMMARY OF LABORATORY METHODS USED TO CLASSIFY CONFIRMED AND PROBABLE CASES OF SPOTTED FEVER RICKETTSIOSES—UNITED STATES, 2010-2015

Alison M. Binder

Centers for Disease Control and Prevention, Atlanta, GA, United States

Spotted fever rickettsioses (SFR) are nationally notifiable diseases in the United States caused by several pathogens including *Rickettsia rickettsii* (the causative agent of Rocky Mountain spotted fever). Case classification is determined using clinical and laboratory criteria. Confirmed cases demonstrate a fourfold change in anti-SFR immunoglobulin G (IgG) serum antibody titers in properly timed paired samples using indirect immunofluorescence antibody (IFA) assay, polymerase chain reaction (PCR), immunohistochemistry (IHC), or culture. Cases are classified as probable when anti-SFR IgG or IgM antibodies can be detected using IFA, enzyme-linked immunosorbent assays (ELISA), dot-ELISA, or latex agglutination (LA). Qualitative assays, infrequently paired specimen collection, and concerns regarding an appropriate threshold of positivity suggest re-evaluation of laboratory criteria. We summarized surveillance data to characterize laboratory methods used to identify SFR cases with onset during 2010-2015 reported in the United States. Using the current SFR national case definition, we determined the proportions of cases identified by each laboratory method. CDC received 14,478 SFR supplemental case reports during 2010-2015. SFR was confirmed in 112 (0.8%) reports, of which 87 demonstrated a fourfold change in IgG titers by IFA, and 25 by PCR, IHC, or culture. The remaining 14,366 (99%) met criteria for probable SFR. Elevated IgG titer was the most commonly reported finding, and was reported in at least one specimen by IFA exclusively (n=9314; 65%) or in combination with other methods (n=2416; 17%); 5522 (47%) recorded one or more titer value <1:128. IFA IgM (3%), ELISA (9%), LA (<.1%), and dot-ELISA (0%) were utilized infrequently independent of other methods. SFR reports rarely show sufficient laboratory evidence to reach confirmed classification. A large proportion of probable cases are supported by a low IgG titer <1:128. Qualitative laboratory criteria and IgM IFAs are used infrequently, can be difficult to interpret, and do not significantly contribute to our understanding of SFR burden in the United States.

828

HOST ASSOCIATION AND PREVALENCE OF RICKETTSIAE IN FLEAS COLLECTED FROM DOMESTIC ANIMALS IN NORTHEAST CAMBODIA

Jeffrey C. Hertz[1], Didot B. Prasetyo[1], Nin Noch[1], Vireak Heang[1], Rithea Leang[2], Rekol Huy[2], Ju Jiang[3], Christina M. Farris[3], Allen L. Richards[3]

[1]Naval Medical Research Unit No. 2, FPO, AE, United States, [2]National Center for Parasitology, Entomology, and Malaria Control, Phnom Penh, Cambodia, [3]Naval Medical Research Center, Silver Spring, MD, United States

Flea-borne rickettsiae are a source of acute undifferentiated febrile illnesses worldwide. These pathogens are present, but are not well understood in Cambodia where poor resources and infrastructure limit the early detection in both humans and vectors. The aim of this study was to measure the prevalence of flea-borne rickettsiae in vector populations from host animals in Rattanakiri and Stung Treng Provinces, Cambodia. From November 2016 to March 2017, fleas were collected from hosts using direct inspection methods, preserved in 70% alcohol, and transferred to the laboratory. A total of 13,068 fleas were collected from dogs, cats, and from murid rodents. Specimens were identified morphologically, pooled by species and host, and stored at -20°C until DNA extraction. Extracted nucleic acids of pooled flea specimens were tested by species-specific qPCR assays. Flea pools containing unidentified *Rickettsia* spp. were subjected to multilocus sequence typing. Four species of fleas were collected from dogs: *Ctenocephalides felis orientis*, *Ctenocephalides felis felis*, *Pulex irritans*, and *Echidnophaga gallinacea*, three species from cats: *C. felis orientis*, *C. felis felis*, and *P. irritans*, and a single flea species, *Xenopsylla cheopis,* was collected from murid rodents. Rickettsiae were identified in all flea species and associated with all host animals, and included detections of *Rickettsia felis, Rickettsia asembonensis,* and Candidatus *Rickettsia senegalensis. Ctenocephalides felis orientis* collected from dogs and *X. cheopis* collected from rodents were found to harbor both *R. asembonensis* and *R. felis* on individual hosts. These findings confirm the presence of flea-borne rickettsiae, including the pathogenic *R. felis,* circulating in flea populations in Northeast Cambodia. More research is needed to understand the burden of rickettsial diseases in Cambodia, which will better inform healthcare professionals, and lead to more accurate diagnoses.

829

GENETIC STRUCTURE AND PHYLOGEOGRAPHY OF *XENOPSYLLA CHEOPIS*, THE FLEA VECTOR OF PLAGUE IN MADAGASCAR

Mireille Harimalala[1], Darren P. Martin[2], Hélène Delatte[3], Romain Girod[1]

[1]Institut Pasteur of Madagascar, Antananarivo, Madagascar, [2]University of Cape Town, Cape Town, South Africa, [3]Centre de coopération Internationale en Recherche Agronomique pour le Développement, Saint Pierre, Réunion

Plague is a zoonotic disease that reaches humans via the bites of infected fleas. Hundreds of plague cases are reported every year in Madagascar where the flea, *Xenopsylla cheopis,* is the transmission vector. Evolutionary analyses of the genetic diversity in fleas can provide information on their population structure and dispersal patterns in relation to disease spread. The aims of this study were both to determine whether *X. cheopis* populations are genetically structured, and to infer the evolutionary history and dispersal patterns of this species at the country level. Nine microsatellite markers were used to genotype 325 individuals from 21 geographic locations. Genetic structure within populations was analysed using Pritchard's clustering method which revealed the existence of two major geographically structured genetic clusters. Whereas fleas from the southeastern and western regions belonged to cluster one, those from

the southwestern regions belonged to cluster two. Flea populations in the northern and eastern regions displayed a high degree of admixture and those in the Central Highlands, which were comprised primarily of cluster two, displayed a moderate degree of admixture. Complete mtCOII sequences were determined and were used together with sequences sampled from elsewhere (ten from La Réunion, three from Mayotte, one from Cambodia, nine from China and seven from Iran) to perform discrete phylogeographic analyses. This analysis suggested that *X. cheopis* may have originated in Madagascar (probability = 0.92). However, the paucity of samples from outside Madagascar means that this result should be interpreted with caution. Pathways of geographical spread were inferred between Madagascar and China and, between locations within Madagascar. This study highlights the occurrence of genetic structure and geographical spread of *X. cheopis* in Madagascar. Genetic admixture at certain locations within Madagascar provides strong evidence that despite the Madagascan *X. cheopis* populations being genetically structured, there is some gene flow between these populations in certain parts of the country.

830

REGIONAL DIFFERENCES IN MORTALITY RISK IN PATIENTS HOSPITALIZED WITH TICK-BORNE DISEASES IN THE UNITED STATES

Jennifer Adjemian, Yi Ling Lai, Emily Ricotta, D. Rebecca Prevots

National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States

Tick-borne diseases are increasing in incidence in the United States, however data on regional differences in clinical outcomes are limited. Using a national database of hospital records, we aimed to identify regional differences in hospitalizations and mortality from tick-borne disease. Data were examined at 156 US hospitals from 2009-2015 in the *Cerner Healthfacts* database to identify hospitalized tick-borne disease cases via administrative codes. Multivariable regression was used to evaluate mortality risk by patient and facility-level factors; adjusted odds ratios (aOR) and 95% confidence intervals (CI) were estimated. Overall, 3,125 hospitalized tick-borne disease patients were identified (mean annual incidence=28 cases/100,000 hospitalized persons): 66% had Lyme disease, 18% tick-borne fever, 14% ehrlichiosis, 6% babesiosis, 3% rickettsiosis, and 5% multiple diagnoses. Cases averaged 49±23 yrs, were 53% male, and had a mean Elixhauser comorbidity index of 2.1±2.0. Among cases, 41 (1.3%) died (mean age=68±16 yrs; range=33-90 yrs). Mortality did not vary by tick-borne disease (p=0.6) but did by region, with rates ≥2-fold greater in the South (2.6%) and West (3.2%) and lower in the Midwest (0.3%) and Northeast (0.6%) (p<0.0001). After controlling for key factors, death was associated with older age (10-unit increase: aOR=1.5, 95% CI=1.2-1.8), higher comorbidity index (1-unit increase: aOR=1.4, 1.2-1.6), and being in the South (aOR=5.9, 95% CI=2.6-13.7; p<0.0001) or West (aOR=10.7, 95% CI=2.4-48.5; p=0.002) versus the Northeast. When evaluated by sub-region, patients in West South-Central states (AR, LA, OK, TX) were 8-times more likely to die (aOR=8.5, 2.6-28.2) compared to those in New England (CT, ME, MA, NH, RI, VT); this area remained at higher risk even when limited to only Lyme disease patients (aOR=8.4, 95% CI=2.0-36.3). Significant differences in mortality exist by US region in hospitalized tick-borne disease patients. High-risk areas may reflect more virulent disease. Greater awareness may also exist in hyperendemic areas, resulting in more rapid diagnosis and treatment to limit severe outcomes.

831

MURINE MODELS OF ROBUST AND WANING SCRUB TYPHUS IMMUNITY UTILIZING HOMOLOGOUS AND HETEROLOGOUS STRAINS OF *ORIENTIA TSUTSUGAMUSHI*

Nicole L. Mendell, Guang Xu, Thomas R. Shelite, Donald H. Bouyer, **David H. Walker**

University of Texas Medical Branch, Galveston, TX, United States

The febrile illness scrub typhus is caused by the obligately intracellular bacterium *Orientia tsutsugamushi*. Unique characteristics of the pathogen and human infection have impeded progress towards a vaccine for protection against this potentially fatal disease. The abundance of *O. tsutsugamushi* strains in the endemic Asia-Pacific region with geographical overlap and poor cross-protective immunity between strains as well as short-lived immunity against the homologous strain in human infection is one such hurdle. To understand this transient immunity, animal models which demonstrate protection and the deterioration of this protection are necessary. We set out to build upon current understanding of this ineffective protection by utilizing our recently developed murine models, sublethal intradermal infection followed by challenge via lethal hematogenous dissemination. Preliminary data from our lab have shown that mice surviving an initial infection with *O. tsutsugamushi* Karp strain are resistant to subsequent lethal homologous challenge after 430 days. After acute infection, passive antibody transfer or immune splenocyte transfer conferred homologous protection from death, whereas more than a year later immune splenocytes alone did not afford complete protection. A different phenotype was observed in mice that were initially infected sublethally with Gilliam strain. Mice which received heterologous challenge after acute infection did not show signs of illness for up to 30 days after Gilliam strain infection. Waning protection indicated by weight loss mirroring the severe course in naïve mice after lethal challenge was observed after challenge with Karp strain at 270 days post initial heterologous infection while protection from death was maintained. At 425 days, 20 percent of mice succumbed to heterologous Karp strain challenge. Elucidation of the antibody and T cell contributions to homologous and heterologous challenge is currently underway and will contribute to understanding the protective immune response, laying the groundwork for development of an effective vaccine.

TUNGIASIS IN MADAGASCAR: A NEGLECTED TROPICAL PARASITE EXACERBATED BY CLIMATE CHANGE?

Nina L. Finley[1], Sarah Zohdy[2], Jussi Eronen[3]

[1]Thomas J. Watson Foundation, New York, NY, United States, [2]Auburn University, Auburn, AL, United States, [3]University of Helsinki, Helsinki, Finland

Itchy, swollen feet are a common occurrence in rural Madagascar thanks to the female sand-flea (*Tunga penetrans* or *T. trimamillata*), an ectoparasite that burrows into skin to drink blood, lay eggs, and die after four to six weeks. Advanced cases of sand-flea disease, or tungiasis, can lead to altered gait, inability to work, secondary infection and death. Previous research in Brazil showed that tungiasis peaks during the dry season and decreases sharply with onset of rains, possibly due to washing-away of the larvae, pupae, and nymphs. In this study, human surveys and climate data were combined to investigate the relationship between climate and tungiasis. Eighty-six residents were interviewed in three rural villages of eastern Madagascar, and data were collected on weather patterns associated with tungiasis. Present-day and model climate data based on four IPCC Representative Concentration Scenarios (RCPs) were used to predict climate and tungiasis prevalence in the years 2050 and 2070. The interviews revealed that rural Malagasy experience a high sand-flea burden, especially children and the elderly. All interviewees had experienced tungiasis, and 10% were actively infected. Active infections were present in 25% of children (<18 years) and 21% of elders (>40 years) but 0% of adults. In total, 91% remove fleas with unsterilized

needles, and 40% reported secondary infections. As prevention, 35% of respondents rub feet with toxic kerosene or insecticide. Of the interviewees, 94% reported that sand-fleas are more common on hot days in the dry-season months of September to December. The results from all four RCPs predict a shortening wet season (precipitation >250 mm), while the dry (<80 mm) and very-dry (<50 mm) seasons are predicted to lengthen. The impact of tungiasis in rural Madagascar is likely to increase with climate change due to a lengthening dry season. This study provides evidence that tungiasis is a neglected tropical disease deserving of higher priority for planetary-health research and control. The presented method of pairing disease seasonality with climate projections can be expanded to endemic regions globally.

833

MOLECULAR CHARACTERISTICS OF *RICKETTSIA* IN TICKS COLLECTED ALONG THE SOUTHERN BORDER OF MONGOLIA

Michael E. von Fricken[1], Matthew A. Voorhees[2], Brandon Lam[3], Jeffrey W. Koehler[2], Susan L. Padilla[2], Barbara Qurollo[4], Carmen Asbun[1], Dulamjav Jamsransuren[5], Dolgorkhand Adiyadorj[5], Uyanga Baasandagwa[5], Battsetseg Jigjav[5], Randal J. Schoepp[6]

[1]Department of Global and Community Health, George Mason University, Fairfax, VA, United States, [2]United States Army Medical Research Institute of Infectious Diseases (USAMRIID), Frederick, MD, United States, [3]Johns Hopkins School of Medicine, Baltimore, MD, United States, [4]Department of Clinical Sciences, College of Veterinary Medince, North Carolina State University, Raleigh, NC, United States, [5]National Center for Zoonotic Diseases, Ulaanbaatar, Mongolia, [6]United States Army Medical Research Institute of Infectious Diseases (USAMRIID), Frederick, Mongolia

Ticks are second only to mosquitoes in their ability to act as vectors of disease. Consequently, workers or populations that frequently enter tick habitats are at an increased risk of contracting a tick-borne disease. This holds true in Mongolia, where pastoral-herders make up 26% of the country's population (of 3 million) and are at high risk of tick bite exposure. A total of 4028 *Dermacentor* and *Hyalomma* ticks were collected from southern Mongolia across five aimags (provinces) including Bayankhongor, Dornogobi, Gobi-Altai, Khovd, and Umnogobi. Ticks were separated into 786 pools by tick genus and location (pool size 2-6 ticks). Extracted genomic material was tested using qPCR methods and primers targeting *rickettsia* 23S-5S ribosomal RNA intergenic spacer. Both Maximum likelihood estimations (MLE) and minimum infection rates were calculated. A total of 505/786 tick pools tested positive for rickettsia bacteria. Based on Mt values, we suspect that at least four, possibly six, different species of *rickettsia* are circulating, based on qPCR melting curves, with major variations in detection rates by sampled region and tick genus. The highest MLE rate of 48.4% (95% CI 41.7-56.5%) was observed in *Dermacentor* ticks from the Gobi-Altai region. Additionally a MLE rate of 7.6% (95% CI 6.2-9.2%) was observed in *Hyalomma* ticks collected in Umnugobi, warranting further testing. Sequence results pending. *Rickettsia* bacteria are circulating at a high rate within native tick species in Mongolia. Further steps are required to identify the exact species of rickettsia circulating in these regions. Given the severity of clinical symptoms of rickettsia in neighboring China and Russia, it is possible these same pathogens are circulating in Mongolia, but the extent remains unclear at this time.

834

THE ROLE OF TWO FEMALE ATRIAL PROTEASES IN THE REFRACTORINESS OF *ANOPHELES GAMBIAE* MOSQUITOES TO FURTHER MATINGS

Priscila Bascunan[1], Paolo Gabrieli[2], Enzo Mameli[1], Robert Shaw[3], Flaminia Catteruccia[1]

[1]Università degli Studi di Perugia, Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]Università degli Studi di Perugia, Italy, [3]Harvard T.H. Chan School of Public Health, Boston, MA, United States

Although the reproductive rate of *Anopheles gambiae* mosquitoes is a key aspect of their capacity to transmit malaria, the fertility of these vectors depends on a single copulation event as females become refractory to mating after a first copulation. Interfering with mating is, therefore, a promising alternative to control mosquito populations in endemic areas, potentially reducing malaria morbidity and mortality. In this study, we show the involvement of two female atrial serine proteases in shaping the mating receptivity of *An. gambiae* females. These two proteolytic enzymes ensure correct processing of the mating plug, a gelatinous structure composed of male seminal secretions that is transferred to the female reproductive tract during mating. We show that correct processing of the plug by these proteases is necessary to trigger a series of events that lead to the reduction of mating receptivity experienced by females after a first copulation. Moreover, these proteases are associated with and possibly contribute to the formation of a peritrophic matrix-like structure secreted by female atrial cells, which surrounds the plug after mating and may be critical for its function. These results shed new light on the mechanisms regulating female receptivity to mating in *An. gambiae*, with possible implications for reducing the reproductive output of these mosquitoes.

CRISPR/CAS9 GENE EDITING TO BLOCK MALARIA TRANSMISSION

Maria L Simões, Yuemei Dong, George Dimopoulos

Johns Hopkins University, Baltimore, MD, United States

The development of genetically modified (GM) mosquitoes for malaria control has gained momentum through the recent advances in gene-drive technology and an increased understanding of vector-pathogen interactions. While most work aiming at the development of GM malaria resistant mosquitoes, suitable for a population replacement strategy, has focused on the over-expression of anti-parasitic genes, here we have explored a strategy relying on CRISPR/Cas9-based inactivation of mosquito encoded *Plasmodium* agonists. During its sporogonic cycle inside the mosquito vector, *Plasmodium* engages in intimate interactions and relies in numerous *Anopheles*-derived host factors, which act as facilitators of infection. The C-type lectins CTL4 and CTLMA2 have been identified as *Plasmodium* agonists (Osta *et al*., 2004). In our recent work we showed that the C-type lectin-mediated protection against parasite melanization in the African vector *A. gambiae* is dependent on infection intensity, rather than the mosquito-parasite combination (Simões *et al*., 2017). RNA interference (RNAi)–based silencing of both lectins resulted in melanization and reduction of live oocysts, albeit RNAi results in only partial gene silencing. We hypothesized that the knockout (KO) of CTL4 would result in complete melanization of the parasites, and consequently a complete halt of *P. falciparum*'s reproductive cycle inside the mosquito. We are currently using CRISPR/Cas9 technology for germline targeted CTL4 KO in *A. gambiae*. We have selected three guide RNA (gRNA) target sequences and generated gRNA-overexpressing *A. gambiae* transgenic lines that were crossed with the Vasa::Cas9 strain and outcrossed with the wildtype docking line, to generate CTL4-KO *A. gambiae* mutants. These CTL4-KO mosquitoes are being studied for their potential parasite blocking and fitness impact of total CTL4 disruption.

836

ASSOCIATION OF THE FREQUENCY OF *KDR* ALLELES V1016L AND F1534C WITH PYRETHROID RESISTANCE IN TWO *AEDES AEGYPTI* POPULATIONS IN PERU

Miriam G. Palomino Salcedo[1], Jesus A. Pinto Caballero[1], Pamela K. Yañez vallejo[1], Henry A. Bonilla Bruno[1], Claudia J. Silva Moreno[1], Audrey E. Lenhart[2]

[1]Instituto Nacional de Salud, Lima, Peru, [2]Centers for Disease Control and Prevention., Atlanta, GA, United States

In Peru, over 20 million people are at risk of *Aedes aegypti*-borne diseases including dengue, Zika and chikungunya. As reports of insecticide resistance increase, vector control efforts may become compromised. Of particular concern is resistance to the pyrethroid class of insecticides. Mutations on the voltage gated sodium channel can contribute to pyrethroid resistance. In Latin America, the principal mutations are V1016I and F1534C, collectively referred to as *kdr*. Wild populations of *Ae. aegypti* were sampled transversally using ovitraps in 2 urban centers, Calleria (jungle) and El Porvenir (coastal). WHO bioassays were conducted to determine susceptibility to permethrin (0.75%) and alpha-cypermethrin (0.05%) in F1 female progeny between 3-5 days old. Following the biosassays, individuals were phenotyped as resistant or susceptible and DNA was extracted. The V10116I and F1534C mutations were detected by real-time PCR. Permethrin and alpha-cypermethrin resistance was detected with bioassay mortalities of 45.4% and 21.8%, respectively, in Calleria, and 58.3% and 95%, respectively, in El Porvenir. The frequencies of the *kdr* alleles differed between the populations. In Calleria, F1534C was fixed (n=93 mosquitoes tested), whereas the frequency was 0.68 El Porvenir (n=71 mosquitoes tested). The frequency of V1016I in Calleria was 0.45, whereas it was only 0.06 in El Porvenir. We detected an association between the V1016I allele and phenotypic resistance to both pyrethroids ($p < 0.05$), suggesting that this mutation is contributing to the resistance observed. However, the F1534C allele was only associated with phenotypic resistance to alpha-cypermethrin ($p<0.01$) but not permethrin ($p>0.05$). All individuals positive for the 1V016I allele also had the F1534C allele.

837

KINETIC AND STRUCTURAL CHARACTERIZATION OF THE GLYCOLYTIC ENZYME PYRUVATE KINASE 1 FROM *AEDES AEGYPTI* MOSQUITOES

Natthida Petchampai[1], Claribel Murillo-Solano[1], Jun Isoe[2], Juan C. Pizarro[1], Patricia Y. Scaraffia[1]

[1]Tulane University, New Orleans, LA, United States, [2]The University of Arizona, Tucson, AZ, United States

A recent study from our laboratory has shown that glucose oxidation is required to support ammonia detoxification in blood-fed *Aedes aegypti* mosquitoes. Pyruvate kinase (PK) catalyzes the last step of the glycolytic pathway. In most organisms, one or more allosteric effectors control PK activity; however, the kinetic properties and conformational structure of PK in mosquitoes have not been previously reported. In this study, two genes (AaPK1 and AaPK2) encoding PK were identified in the *A. aegypti* genome. The gene AaPK1, which encodes a 529 amino acid protein with an estimated molecular weight of ~57 kDa, was cloned and the recombinant protein was expressed and purified in bacteria. AaPK1 kinetic parameters were determined. Multiple allosteric effectors of AaPK1 were identified and the binding of those molecules was analyzed by a thermal shift assay. The recombinant protein was also crystallized and its 3D structure determined at 4Å resolution. We found that Ala, Gln, Pro, Ser or fructose-1-phosphate displayed a classic allosteric activation on AaPK1. We also found that ribulose-5-phosphate acted as an allosteric inhibitor of AaPK1, but its inhibitory effect was reversed in the presence of some amino acids (AAs). In addition, the allosteric activation of AaPK1 by AAs was abolished in the presence of fructose-1,6-bisphosphate (F16BP). Moreover, the allosteric activation of AaPK1 by Ala and Ser was diminished by the addition of glucose-6-phosphate. Interestingly, the addition of F16BP or the mixture of F16BP and specific AAs increased the melting temperature of the enzyme, confirming the association between the sugar, the AAs and the enzyme. The AaPK1 structure shows the presence of two independent allosteric sites. All together, our data reveal how specific AAs and phosphorylated sugars tightly regulate conformational dynamics and catalytic changes of AaPK1. Mechanistic insights from our data can aid in the understanding of the role of AaPK in sugar- and blood-fed mosquitoes.

838

A ROLE FOR THE JNK PATHWAY IN 20E-DEPENDENT OVIPOSITION IN *ANOPHELES GAMBIAE*

Matthew J. Peirce[1], Paolo Scarpelli[1], Evdoxia G. Kakani[2], Sara N. Mitchell[2], Adam South[2], Kristine L. Werling[2], Perrine Marcenac[2], Vincenzo N. Talesa[1], Flaminia Catteruccia[2]

[1]University of Perugia, Perugia, Italy, [2]Harvard T.H. Chan School of Public Health, Boston, MA, United States

The reproductive success of the *Anopheles gambiae* mosquito is a major determinant of its capacity to transmit the malaria-causing parasite, *Plasmodium falciparum*. We recently demonstrated that 20 hydroxyecdysone (20E), an ecdysteroid hormone transferred from male to female during copulation, licences the female to oviposit developed eggs. However, the molecular mechanisms and signalling pathways driving this lifelong behavioural switch remain incompletely understood. Microarray analysis of females before and after mating revealed a head-specific, mating-associated gene signature enriched in transcripts associated with wounding and melanisation, two responses linked to the activation of the Jun N-terminal Kinase (JNK) pathway. This link between mating and JNK signalling was confirmed by western blotting documenting an increase in phosphorylated JNK (pJNK, the active form of the kinase) in the heads of mated females. Notably, RNAi-mediated depletion of JNK, or the transcription factors Jun and Fos that act downstream of JNK, partially inhibited mating-induced oviposition, demonstrating a requirement for the JNK pathway in this mating outcome. Conversely, activation of the JNK pathway in virgin females by RNAi-mediated depletion of the JNK phosphatase, Puckered, a negative regulator of the JNK pathway, was able to mimic both the biochemical (activation of JNK in the head), and biological (induction of oviposition) consequences of mating, suggesting that activation of the JNK pathway was sufficient *per se* to induce oviposition. A second oviposition stimulus in the form of exogenous 20E, injected in to virgin females, induced a similar activation of JNK in the head, whereas the oviposition normally observed blood-fed virgins after 20E injection was significantly reduced in females depleted of JNK pathway components. Together, these data demonstrate an unexpected requirement for the JNK pathway, more traditionally associated with immunity and stress resistance, in 20E-dependent post-mating responses in the most important vector of malaria.

STEROID HORMONE SIGNALING REGULATES *PLASMODIUM FALCIPARUM* DEVELOPMENT IN THE *ANOPHELES GAMBIAE* FEMALE

Kristine Werling, Maurice Itoe, Robert Shaw, Kathleen Westervelt, Andrea Smidler, Adam South, Flaminia Catteruccia

Harvard TH Chan School of Public Health, Boston, MA, United States

Anopheles gambiae are the major African vectors of the malaria parasite *Plasmodium falciparum*. The vectorial capacity of these mosquitoes is partly due to their high reproductive rate as well as their ability to support *Plasmodium* development—these two processes are intimately linked since when a female mosquito takes an infected blood meal, oogenesis and parasite development proceed concurrently. Here we examined whether sporogonic development of *Plasmodium* parasites is influenced by processes driving oogenesis. After infecting *An. gambiae* females

with a *P. falciparum* culture, we found an unexpected positive correlation between the number of eggs a female mosquito develops and the number of oocysts found in her midgut. Furthermore, transgenic ablation of ovarian germ cells prior to infection caused a significant decrease in parasite numbers, indicating that infection depends on the occurrence of oogenesis. We next enzymatically impaired the function of the steroid hormone 20-hydroxyecdysone (20E), a key factor in the regulation of oogenesis, and found that reducing hormone titers also reduces parasite numbers. Moreover, disrupting 20E signaling via RNAi silencing of the 20E nuclear Ecdysone Receptor (EcR) breaks the positive egg-parasite interaction, implicating 20E in regulating reproduction-immunity trade-offs. Strikingly, however, disrupting 20E signaling induces faster parasite development, leading to more salivary gland sporozoites at earlier time points post blood meal. Lipidomic analyses of blood meal-induced changes show that the effects of hormone signaling on the parasite extrinsic incubation period (EIP) are likely due to 20E-mediated accumulation of neutral lipids in the midgut post blood meal. Consistently, interfering with lipolytic pathways by silencing a mosquito TAG Lipase phenocopies the effects of *EcR*-silencing by inducing faster parasite development—although the mechanism by which parasites utilize lipids is still being determined. Overall, these data demonstrate a remarkable influence of steroid hormone signaling on vector-parasite interactions critical for malaria transmission.

840

THE ROLE OF THE *ANOPHELES* LIPOLYTIC MACHINERY IN MOSQUITO REPRODUCTION AND *PLASMODIUM FALCIPARUM* DEVELOPMENT

Maurice A. Itoe[1], Kristine Werling[1], Amy Deik[2], Duo Peng[1], Clary Clish[2], Flaminia Catteruccia[1]

[1]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]Broad Institute of Harvard and Massachusetts Institute of Technology Cambridge, MA, United States

Normal 0 false false false EN-US X-NONE X-NONE /* Style Definitions */ table.MsoNormalTable {mso-style-name:"Table Normal"; mso-tstyle-rowband-size:0; mso-tstyle-colband-size:0; mso-style-noshow:yes; mso-style-priority:99; mso-style-parent:""; mso-padding-alt:0in 5.4pt 0in 5.4pt; mso-para-margin:0in; mso-para-margin-bottom:.0001pt; mso-pagination:widow-orphan; font-size:12.0pt; font-family:"Calibri",sans-serif; mso-ascii-font-family:Calibri; mso-ascii-theme-font:minor-latin; mso-hansi-font-family:Calibri; mso-hansi-theme-font:minor-latin;} Once mobilized, lipids are loaded onto lipophorin, in the hemolymph, for delivery to various tissues such as ovaries, fat body, and flight muscles. Here, we elucidated the specific role of lipid mobilization in shaping both *Anopheles gambiae* reproduction and *Plasmodium falciparum* parasite development in the female mosquito. We initially performed targeted lipidomic analyses of various mosquito tissues after a blood meal to assess dynamic changes in major lipids, especially triacylglycerols (TAGs) and other neutral lipids. These analyses revealed a coordinated accumulation and depletion of TAGs, DAGs, MAGs, and CE across key mosquito tissues, suggesting the occurrence of lipolytic and lipogenic pathways. Bioinformatics analysis of the *Anopheles* lipolytic machinery involved in the mobilization of TAGs, revealed the presence of a putative TAG lipase that appears to be specific to insects. RNA interference (RNAi) against this TAG lipase and an associated protein that is generally involved in the breakdown of TAGs identified lipid mobilization as central in determining reproductive success of the main malaria vector. Specifically, TAG lipase silencing significantly impaired lipid mobilization from the midgut, reduced egg development, and abolished fertility. Interestingly, while silencing of this lipase did not affect *P. falciparum* oocyst numbers, it induced faster parasite development. This study identifies the regulation of TAG/DAG equilibrium as critical for the reproductive success of *Anopheles* mosquitoes.

841

A CASCADE OF TYROSINE KINASE PHOSPHORYLATION REGULATES EGG DEVELOPMENT IN *ANOPHELES GAMBIAE* MOSQUITOES

Simona Ferracchiato[1], Matthew Peirce[2], Flaminia Catteruccia[1]

[1]Harvard T. H. Chan School of Public Health, Boston, MA, United States, [2]Università degli Studi di Perugia, Perugia, Italy

Anopheles gambiae mosquitoes are the principal vectors of the malaria-causing parasite, *Plasmodium falciparum.* The high reproductive rate of these females is strictly related to egg production, an intricate process which requires vertebrate blood in order to accumulate nutrients for later development of the embryo. The steroid hormone 20-hydroxy-ecdysone (20E), found throughout life in both females and male, is responsible for most of the changes that occur in female during this process. Modification of the function or the way in which acts this hormone could generate new opportunities to reduce the number of females transmitting malaria. To this aim, we focused on decoding the complex signaling cascades triggered by blood feeding that lead to egg development in the female *A. gambiae* mosquitoes. Our studies show that the 20E partly regulates oogenesis via a pathway that involves activation of tyrosine kinases to enhance protein tyrosine phosphorylation of an array of different proteins, which in turn might contribute to the 20E-induced physiological changes leading to oogenesis. Injection of a tyrosine kinase inhibitor reduces the number of eggs developed after blood feeding, and results in additional egg development defects, suggesting that tyrosine phosphorylation might play a pivotal role in the correct outcome of the reproductive cycle. Moreover, enzymatically blocking the function of 20E reduces tyrosine phosphorylation levels after blood feeding, suggesting the latter process is regulated by 20E signaling cascades. More detailed analysis revealed that the released 20E after a blood meal induces phosphorylation of phospholipase C gamma (PLCγ), an important mediator of growth. Silencing of this PLCγ lead to a significant decrease in the number of eggs, phenocopying the results obtained with the tyrosine kinase inhibitor and the effects of 20E on PLC appear mediated by the 20E nuclear hormone receptors, Ecdysone Receptor (EcR). Our results reveal novel signaling pathways that are involved in translating the 20E signal into egg development and may help designing novel methods to reduce the reproductive fitness of *A. gambiae* females.

THE 20 TOOLS OF VECTORBASE: A BIOINFORMATICS AND POPULATION BIOLOGY RESOURCE FOR INVERTEBRATE VECTORS OF HUMAN PATHOGENS

Gloria I. Giraldo-Calderon[1], Daniel Lawson[2], Scott J. Emrich[3], Frank Collins[1], VectorBase consortium[4]

[1]University of Notre Dame, Notre Dame, IN, United States, [2]Imperial College London, London, United Kingdom, [3]University of Tennessee, Knoxville, TN, United States, [4]EMBL-EBI, Hinxton, United Kingdom

VectorBase.org is a free online resource that provides 20 different tools, including four new ones made available in the last year. Visit us in the exhibit hall for a demonstration of any of these tools with your species or data set of interest. If you never used VectorBase or you are a novice user, we recommend you start with the Genome Browser or with 'Find a Data Display (new!)', with this tool you can choose a gene, region or variant, and obtain an automatic generation of the relevant visualizations that include many different types of figures and tables. Some of the other 20 VectorBase tools are briefly described as follows. Apollo is an instantaneous, collaborative, genome annotation editor, designed to support geographically dispersed researchers. Search, Advanced Search and BioMart, are used for simple and complex, big and small-scale data mining queries. BLAST finds regions of local similarity between sequences. HMMER looks for homologous genes, but unlike BLAST it aims to be more accurate and better to detect remote homologs. A background pipeline

generates Comparative Genomics data, browse for precomputed displays of protein (e.g., gene trees) and DNA comparisons. The Expression Browser and Map has microarray and RNAseq data from different experiments showing differential expression, all data is processed through the same pipeline so that results can be compared side-by-side. Use the Genotype Explorer (new!) to browse variation such as SNPs and INDELs in field samples, and the Variant Effect Predictor (VEP) to determine the effect of variants on genomes. Galaxy is an open, web-based platform for data intensive biomedical research. The Population Biology (PopBio) resource is used for visualization, search and analysis of population data, including genotypes and phenotypes, mostly from field collections. Use a map or the Sample Explorer (new!) to query the metadata from the Genome Browser and PopBio samples. The REST API (new!) provides direct programmatic access to VectorBase species data. For Help or feedback email info@vectorbase.

ADOPTION OF HOUSEHOLD VECTOR CONTROL BEHAVIORS FOR *AEDES AEGYPTI* AMONG AT-RISK POPULATIONS IN FOUR COUNTRIES

Martha Silva Acuna[1], Lina M. Moses[2], Jessie Pinchoff[3], Jeni Stolow[2], Paul Hewett[4], Paul Hutchinson[2]

[1]Tulane University - Seconded to Population Council, Washington, DC, United States, [2]Tulane University, New Orleans, LA, United States, [3]Population Council, New York, NY, United States, [4]Population Council, Washington, DC, United States

Zika is a public health concern that, if acquired during pregnancy, has particularly adverse impacts on neonatal and child health. Since the onset of the epidemic in the Americas in 2015, there have been 3,720 confirmed cases of congenital Zika syndrome, named for a cluster of birth defects associated with Zika virus infection, including severe microcephaly. However, 80% of adults infected with Zika are asymptomatic, leading to low perceived severity of the disease. Dengue and Chikungunya are considered endemic in the region and, compared with Zika, have higher mortality rates and confer much more debilitating symptoms in both adults and children. With the recent Zika epidemic, the U.S.G. Department of State dedicated funding for the Zika response in April 2016, prioritizing efforts and programming to minimize negative pregnancy outcomes in South and Central America and the Caribbean. The Zika response is being implemented in a setting where other *Aedes aegypti*-borne diseases have long been public health concerns. In this context, a cross-sectional household survey will be implemented between April and June 2018 in targeted USAID programming implementation areas in the Dominican Republic, Guatemala, El Salvador and Honduras (N=2400). The survey will collect information on individuals' knowledge, risk perceptions, individual and household vector control practices, self-efficacy, perceived ease of practice of prevention behaviors, and injunctive social norms pertaining to prevention practices. This research will assess the comparative perceived risk and perceived severity of Zika, Dengue and Chikungunya, and how these perceptions modulate vector control and prevention practices within households. The objective is to inform prevention strategies aimed at using social and behavior change campaigns to increase adoption of household vector control activities that will reduce transmission of diseases by the *Aedes aegypti* vector.

844

RESISTANCE OF *AEDES AEGYPTI* POPULATIONS TO DELTAMETHRIN, PERMETHRIN, AND TEMEPHOS IN CAMBODIA

Sébastien Boyer[1], Sergio Lopes[2], Didot B. Prasetyo[3], **John Hustedt**[4], Sarady S. Ay[2], Dyna Doum[2], Sony Yean[1], Borin Peng[1], Vibol Chan[5], Bunleng Sam[6], Rithea Leang[6], Didier Fontenille[1], Jeffrey Hii[2]

[1]Institut Pasteur du Cambodge, Phnom Penh, Cambodia, [2]Malaria Consortium, Phnom Penh, Cambodia, [3]United States Naval Medical Research Unit-2, Phnom Penh, Cambodia, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom, [5]World Health Organization, Phnom Penh, Cambodia, [6]National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia

Dengue fever is a major public health concern in Cambodia with over 185,000 cases reported annually. *Aedes aegypti* is the primary vector for dengue transmission and is currently targeted with insecticide treatments during outbreaks. This study characterized the insecticide resistance status of 8 populations of *Ae. aegypti* from four different geographical areas. Urban and rural villages were selected as collection points within each area. Villages were selected by the National Dengue Control Program according to geographical representation, dengue incidence, and recent use of temephos (within the previous 2 years). The susceptibility of *Ae. aegypti* to temephos, permethrin, and deltamethrin was evaluated in accordance with World Health Organization protocols and test kits. All the field populations showed resistance to temephos compared with the sensitive strain with resistance ratio 50 (RR_{50}) varying from 3.3 to 33.78 and RR_{90} from 4.2 to 47 compared with the sensitive strain, demonstrating an installed and generalized resistance of larvae to the temephos in Cambodia. *Ae aegypti* adult populations were highly resistant to permethrin regardless of province or rural/urban classification with an average mortality of 0.02%. Seven of the 8 field populations showed resistance to deltamethrin. These results and those of neighboring countries are alarming. From a regional point of view, it seems essential to rapidly change control methods and replace temephos with another intervention. These results are alarming for dengue vector control, as widespread resistance may compromise the entomological impact of larval control operations. Unfortunately, loss of susceptibility to these insecticide classes limits the efficacy of interventions in the event of an epidemic and impact on emergency suppression of Aedes mosquitoes. Regular continuous monitoring of resistance is necessary in order to select the most effective adulticides for dengue control in Cambodia.

845

AN EVALUATION OF THE EFFICACY OF AIRCRAFT DISINSECTION PROCEDURES AT AUSTRALIAN AIRPORTS

Oselyne Ong[1], Lisa Rigby[2], Gordana Rasic[1], Angus Sly[3], Gregor Devine[1]

[1]QIMR Berghofer Medical Research Institute, Herston, Australia, [2]Australian Defence Force Malaria and Infectious Disease Institute, Brisbane, Australia, [3]Department of Agriculture and Water Resources, Australia, Brisbane, Australia

The inadvertent transport of live *Aedes aegypti* on aircraft originating from disease-endemic countries is a problem for Australia's biosecurity measures. Recently, our international airports have intercepted an unprecedented number of exotic mosquitoes during routine surveillance, which suggests 1) existing aircraft disinsection procedures are inadequate, and 2) airports are a likely source of exotic invasions. Mosquitoes captured at 8 Australian ports revealed that 996P and 1023G knock-down resistant (*kdr*) mutations were present in 53 out of 79 mosquitoes. Susceptible mosquitoes caught in northern Queensland airports were deemed local as *A. aegypti* in the area lack *kdr* mutations. The World Health Organization (WHO) recommends 0.2 g/m^2 of permethrin as the target dose for residual aircraft treatments, and is designed to kill landing

mosquitoes over 8 week intervals despite the gradual decay of residues (the lower tolerable threshold is 2 mg/m^2). A resistant *A. aegypti* colony at 100% 996P/1023G *kdr* mutation frequencies was used as proxy for mosquitoes intercepted at Australian airports to determine the impacts of WHO recommended permethrin doses on various aircraft surfaces. Results revealed the operational impact of residual treatments to be low, even for susceptible mosquitoes on some surfaces. Bioassays performed on permeable surfaces (i.e. carpets) with 0.2 g/m^2 permethrin showed mortality of <50% in susceptible mosquitoes exposed for 30 min. High-performance liquid chromatography (HPLC) analysis of swabs taken from permeable surfaces revealed that permethrin recovery was considerably less than the applied amount. Using free flight rooms and mosquitoes displaying natural resting and flying behaviours, we also showed that patchily treated environments typical of treated aircraft cabins and holds do not result in the universal exposure of mosquitoes. This study provides evidence of the ineffectiveness of aircraft disinsection procedures, at least in relation to residual treatments. New chemistries and more effective application methods are desperately required to protect our airports and most vulnerable territories.

846

AEDES POPULATIONS AND THEIR SUSCEPTIBILITY TO INSECTICIDES IN KINSHASA, DR CONGO

Fabien C. Vulu[1], Mitterrand Moyo[1], Japhet Kabalu[1], Stella Nyota[1], Heritier Kayembe[1], Patrick Mamona[1], David Weetman[2], Seth Irish[3], Thierry Bobanga[1]

[1]Service de Parasitologie et d'Entomologie médicale, Département de Médecine Tropicale, Faculté de Médecine, Université de Kinshasa, Kinshasa, Democratic Republic of the Congo, [2]Department of Vector Biology, Liverpool School of Tropical Medicine, Pembroke Place, Liverpool, United Kingdom, [3]Entomology Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, DC, United States

Aedes aegypti and *Ae. albopictus* mosquitoes transmit several important viruses to humans such as yellow fever, dengue, chikungunya and zika. The health threat posed by Aedes borne viruses is rising especially in urban environments. In the absence of curative treatments against arboviruses, vector control remains essential, and many rely on the use of insecticides. With Aedes increasingly resistant to insecticides, updated data on susceptibility is needed to guide control measures. The Democratic Republic of Congo (DRC) is one of the countries highly threatened by arbovirus outbreaks. Despite the long-standing risk, data about Aedes are lacking. This study aimed to determine population and susceptibility to insecticides of Aedes in Kinshasa. Aedes larvae were collected in Kinshasa from January to June 2017. They were reared to adults and identified to species following Huang and Highton morphological keys. WHO tube assays were carried out to assess susceptibility of female *Ae. aegypti* and *Ae*. *Albopictus*. 8,798 adult mosquitoes were obtained from aquatic stages of which 62% were Aedes, which comprised of three species: *Ae. aegypti* (29%), *Ae. albopictus* (70%), and *Ae. vittatus* (0.5%). All sampled *Ae. aegypti* belonged to the *formosus* subspecies. Mortalities recorded from WHO tube assays indicated high prevalence of resistance to DDT (25 and 36% for *Ae. aegypti* and *Ae. albopictus*, respectively), confirmed resistance to deltamethrin (73 and 92%), marginal suspected resistance to permethrin (97 and 100%), and propoxur (98 and 100%), but full susceptibility to bendiocarb and malathion (all 100%). This study is the first to provide distribution and data on susceptibility of *Aedes aegypti* and *Aedes albopictus* to insecticides in Kinshasa. With the exception of DDT, most tests indicate limited resistance and provide valuable baseline data for future studies and to guide control measures. More studies on Aedes populations and their susceptibility to insecticides, and mechanisms involved in resistance are needed across DRC.

847

A WHOLE TRANSCRIPTOMIC APPROACH TO CHARACTERIZE INSECTICIDE RESISTANCE MECHANISMS IN *ANOPHELES ARABIENSIS* (DIPTERA: CULICIDAE) FROM ETHIOPIA

Louisa A. Messenger[1], Delenasaw Yewhalaw[2], Lucy Mackenzie Impoinvil[3], Matt Burrows[3], Jonathan Gerhart[3], Audrey Lenhart[3], Seth Irish[4]

[1]American Society for Microbiology Fellow, Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Jimma University, Jimma, Ethiopia, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]President's Malaria Initiative, Centers for Disease Control and Prevention, Atlanta, GA, United States

The development of widespread insecticide resistance is of increasing concern in Ethiopia because of its implications for malaria vector control failure. To improve our understanding of the specificity of resistance mechanisms and to facilitate the design of management strategies that minimize the likelihood of selecting for cross-resistance, we undertook an exploratory transcriptomic approach to identify markers of metabolic resistance in *Anopheles arabiensis*. A total of 237 *An. arabiensis* were collected as blood-fed adults from house walls in Asendabo, Oromia Region in July-September 2017. F_1 progeny, generated by forced-oviposition, were phenotyped as resistant or susceptible to malathion and permethrin using standard CDC bottle bioassays. Target site resistance markers (L1014F *kdr* and G119S *Ace-1*) were screened using PCR. RNA was extracted from bioassay survivors, unexposed individuals, and susceptible reference populations and submitted for Illumina RNA-sequencing. The average mosquito mortality was 72% (range of 61-83%) and 77% (50-100%) when exposed to the diagnostic doses of malathion and permethrin, respectively. This population demonstrated intense deltamethrin resistance (average mortality of 84% at 10X the diagnostic dose) but was fully susceptible to carbamates (bendiocarb and propoxur). *Ace-1* mutations were not present in any mosquitoes tested in malathion bioassays (n=173). The L1014F *kdr* mutation was detected in 52% (30/58) of permethrin-exposed *An. arabiensis*, with allele frequencies of 0.65 and 0.26 in surviving and dead mosquitoes, respectively. Analysis of RNA-seq data is ongoing to identify candidate genes associated with resistance. The absence of *Ace-1* target site polymorphisms and the moderate *kdr* allele frequency suggest that metabolic mechanisms are likely driving organophosphate resistance and contributing to pyrethroid resistance in this population. As little is known about the molecular basis of metabolic resistance in *An. arabiensis*, these results will provide the most comprehensive analysis in this species to date.

848

VARIABLE RESISTANCE TO INSECTICIDE IN *AEDES AEGYPTI* IS EXPLAINED BY COMBINED *KDR* MUTATIONS AND METABOLIC GENE OVEREXPRESSION IN BURKINA FASO

Athanase Badolo[1], Aboubacar Sombié[1], Patricia Pignatelli[2], Dimitri W. Wangrawa[1], Felix Yameogo[1], Aboubacar Sanon[1], Antoine Sanon[1], Hirotaka Kanuka[3], Philip J. McCall[2], David Weetman[2]

[1]Université Ouaga 1 Pr Joseph Ki-Zerbo, Ouagadougou, Burkina Faso, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]University of Jikei, Tokyo, Japan

Aedes aegypti control in Burkina Faso is an urgent concern owing to recurrent and expanding dengue outbreaks. The situation of *Ae. aegypti* resistance to insecticides in Africa suffers from lack of data and, for the available data, heterogeneity of resistance, which may have a temporal, methodological or biological explanation. We report here the insecticide resistance situation for *Aedes aegypti* in Burkina Faso. Larvae were collected from the most representative breeding sites in urban, semi-urban and rural localities of Burkina Faso. WHO and CDC protocols bioassays were performed on larvae and adults using insecticides from

the four major classes and in somed cases included the synergist PBO. Taqman RT-PCR was used to check for knockdown resistance (kdr) mutations. Quantitative Real-time PCR was used to analyze the expression of candidate P450 genes potentially involved in insecticide resistance. Larval stages displayed susceptibility to organophosphates with highest lethal concentrations (LC50 and LC99) generally recorded in the urban localities. Adult resistance to insecticides varied according to locality and breeding site. As elsewhere in Africa (where recorded) Ae. aegypti were susceptible to organophosphates but suspected to be resistant to carbamates in the urban area. The urban and semi-urban populations were resistant to permethrin and deltamethrin with at least partial restoration of susceptibility by PBO, whereas in contrast, the rural area population was susceptible to the insecticides tested. Molecular analysis reveal the presence of the V1016I and F1534C knockdown resistance (kdr) mutations and the absence of S989P and V1016G. The frequency of each kdr mutation was higher in the urban and semi-urban areas than in the rural area. Quantitative PCR analysis of expression of metabolic resistance candidate genes detected an aggregate overexpression of P450 genes, which combined with kdr mutations is likely to explain the phenotypic resistance differences observed.

849

FINE-SCALE SPATIAL AND TEMPORAL HETEROGENEITIES IN INSECTICIDE RESISTANCE PROFILES OF *ANOPHELES ARABIENSIS* IN RURAL SOUTHEASTERN TANZANIA

Nancy S. Matowo[1], Givemore Munhenga[2], Marcel Tanner[3], Maureen Coetzee[2], Wim F. Feringa[4], Lizette L. Koekemoer[2], Halfan S. Ngowo[1], Fredros O. Okumu[1]

[1]Ifakara Health Institute, Dar-es Salaam, United Republic of Tanzania, [2]Wits Research Institute for Malaria, MRC Collaborating Centre for Multi-disciplinary Research on Malaria, School of Pathology, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [3]Swiss Tropical and Public Health Institute, Basel, Switzerland, [4]Faculty of Geo-Information Science and Earth Observation, University of Twente, Enschede, Netherlands

Programmatic monitoring of insecticide resistance in disease vectors is mostly done on a large scale, often focusing on differences between districts, regions, or countries. However, local heterogeneities in residual malaria transmission imply the need for finer-scale data. This study reports small-scale variations of insecticide susceptibility in *Anopheles arabiensis* between three neighbouring villages across two seasons in Tanzania, where insecticidal bed nets are extensively used, but malaria transmission persists. WHO insecticide susceptibility assays were conducted on female and male *An. arabiensis* from three proximal villages, Minepa, Lupiro, and Mavimba, during dry (June-December 2015) and wet (January-May 2016) seasons. Adults emerging from wild-collected larvae were exposed to lambda-cyhalothrin, deltamethrin, permethrin, DDT, dieldrin, bendiocarb, propoxur, pirimiphos-methyl and malathion. A hydrolysis probe assay was used to screen for L1014F (*kdr-w*) and L1014S (*kdr-e*) mutations in specimens resistant to DDT or pyrethroids. Synergist assays using piperonly butoxide (PBO) and triphenol phosphate (TPP) were done to assess pyrethroid and bendiocarb resistance phenotypes. There were clear seasonal and spatial fluctuations in phenotypic resistance status in *An. arabiensis* to pyrethroids, DDT and bendiocarb. Pre-exposure to PBO and TPP, resulted in lower knockdown rates and higher mortalities against pyrethroids and bendiocarb, compared to tests without the synergists. Neither L1014F nor L1014S mutations were detected. This study confirmed the presence of pyrethroid resistance in *An. arabiensis* and showed small-scale differences in resistance levels between the villages, and between seasons. Substantial, though incomplete, reversal of pyrethroid and bendiocarb resistance following pre-exposure to PBO and TPP, and absence of *kdr* alleles suggest involvement of P450 monooxygenases and esterases in the resistant phenotypes. Further bioassays are recommended to quantify the strength of resistance, both biochemical and molecular analysis to elucidate specific enzymes responsible in resistance.

850

EFFICACY OF TWO TYPES OF PYRETHROID AND PIPERONYL BUTOXIDE (PBO) COMBINATION NETS (OLYSET PLUS AND PERMANET 3.0) AGAINST PYRETHROID RESISTANT MALARIA VECTORS IN SOUTHERN BENIN

Corine A. Ngufor

London School of Hygiene & Tropical Medicine, London, United Kingdom

The efficacy of Long-lasting insecticidal nets is today threatened by widespread resistance to pyrethroids; the insecticide of choice for treating bed-nets. PBO, a synergist that inhibits specific metabolic enzymes within mosquitoes has been combined with pyrethroids to enhance the potency of bed-nets against pyrethroid resistant vector populations. Five PBO and pyrethroid combination nets with varying characteristics and technical specifications have to-date received interim WHO recommendation for field use. In this study, we compared the efficacy and wash resistance of two types of PBO plus pyrethroid combination nets (Olyset Plus and Permanet 3.0) against pyrethroid resistant malaria vectors in experimental huts in Cove, Southern Benin.Laboratory assays were performed to help explain the findings in the experimental huts. Mortality rates of malaria vectors from the experimental hut station exposed to pyrethroids in CDC bottle bioassays increased significantly after pre-exposure to PBO (from 30% to 70%) demonstrating the presence of mixed-function oxidases in the vector population. Mortality of wild free-flying pyrethroid resistant An gambiae entering the experimental huts was only 22% with Olyset Net (a pyrethroid-only net). The PBO+pyrethroid LLINs killed significantly higher proportions of mosquitoes than Olyset Net. Mortality was significantly higher with Permanet 3.0 (44%) than Olyset Plus (32%) when both LLINs were unwashed ($P<0.05$). With nets washed 20 times, mortality decreased significantly with Permanet 3.0 (from 44% unwashed to 17% after 20 washes, $P<0.05$) but did not change significantly with Olyset Plus (32% unwashed vs. 28% washed 20 times, $P>0.05$). In conclusion, both types of PBO nets demonstrated improved efficacy against pyrethroid resistant malaria vectors compared to a standard pyrethroid-only LLIN. Permanet 3.0 showed a greater effect when unwashed while Olyset Plus was substantially more wash resistant.

851

ASSOCIATION BETWEEN *VGSC*1014 ALLELES AND FEEDING PATTERNS OF *PHLEBOTOMUS ARGENTIPES*

Bruno Gomes[1], Vijay Kumar[2], Pradeep Das[2], Mark Paine[3], Dinesh Mondal[4], David Weetman[3]

[1]Oswaldo Cruz Institute (IOC-FIOCRUZ), Rio de Janeiro, Brazil, [2]Rajendra Memorial Research Institute of Medical Sciences (Indian Council of Medical Research), Patna, India, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [4]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Control of the sandfly vector *Phlebotomus argentipes* is an essential tool for visceral leishmaniasis elimination in the Indian subcontinent disease hotspot. Currently, the main control measures are based on pyrethroid insecticides that share cross-resistant mechanisms with DDT, notably knockdown resistance *(kdr)* mutations in the para voltage-gated sodium channel (*Vgsc*). We detected three *kdr* mutations linked strongly with DDT resistance and predictive of pyrethroid tolerance in *P. argentipes.* Here we present results on *kdr* distributions in relation to sandfly control activities to better understand selection and operational impacts of insecticide resistance. We screened a temporal sample of *P. argentipes* females from Mymensingh (Bangladesh), collected during a pyrethroid-based indoor residual spraying (IRS) programme, for *Vgsc*-1014 alleles using TaqMan assays and blood meal origin using two PCR assays. In Mymensingh, all *kdr* mutations were less common than in Bihar (India) potentially suggesting a lower current or past selective pressure. Data from Bihar showed *kdr* frequencies covaried spatially with intensity of DDT (and now pyrethroids) IRS programmes, but in Mymensingh temporal trends in *kdr* did not link

with IRS implementation. However, most *P. argentipes* with human blood exhibited *kdr* genotypes (81%), including a large fraction possessing the phenylalanine alleles (52%) associated with the strongest resistance phenotypes. In contrast, sand flies with animal blood meals possessed primarily wild type leucine allele ($\chi^2_3 = 96.09$; $P << 0.001$). This strong association between human feeding and *kdr* mutations in a region with pyrethroid spraying suggests an operational impact of *P. argentipes kdr* and provides further evidence to support screening of *kdr* mutations in surveillance and control programs.

IDENTIFICATION OF SEX SPECIFIC ACTIN GENES IN *ANOPHELES ALBIMANUS*, A MAIN MALARIA VECTOR IN CENTRAL AMERICA AND THE CARIBBEAN

Claudia Paiz-Reyes, Pamela Flores, Katia Illescas, Mabel Taracena, Norma Padilla, Pamela Pennington

Universidad del Valle de Guatemala, Guatemala, Guatemala

Malaria is a life threatening disease that affects millions of people worldwide. There are four *Plasmodium* species that can cause malaria when transmitted to humans by female *Anopheles* mosquitoes. *Anopheles albimanus* is one of the two main vectors of malaria in the Mesoamerican region where the transmission of the disease is still active. In Guatemala, despite the distribution of insecticide treated nets malaria persists, focalized transmission in several departments is persistent. The Sterile Insect Technique (SIT) is a biological control method that can reduce insect pests by releasing a large number of sterile males, but the mosquito rearing process and fitness cost to the males still need to be improved. Sex sorting is one of the key steps of the production that need new technologies to be more efficient in a large scale production. The SIT was successful in the 1970´s at controlling *An. albimanus* in a lake ecosystem in El Salvador. In *Aedes sp*. mosquitoes, there are sex specific muscle actins and the indirect flight muscle actin promoter has been used to produce flightless females by the Release of Insects Carrying Dominant Lethal (RIDL) system. With the aim of improving SIT and to develop a method to target females, we extracted RNA and performed 3´-RACE to differentiate the actins expressed throughout the *An. albimanus* life cycle. Interestingly, we found four sex specific actins, two female-specific and two male-specific. Our current studies will evaluate the effects of knocking down these sex-specific genes. Our research could potentially result on a genetic methodology to selectively eliminate the females from the production of sterile male mosquitoes for release, making this process cheaper and more feasible to implement in the region.

853

ATTRITION, BIOLOGICAL EFFICACY, INSECTICIDE RESIDUE AND PHYSICAL DEGRADATION OF LONG LASTING INSECTICIDAL NETS USED FOR MALARIA CONTROL AND ELIMINATION IN THE PHILIPPINES

Ferdinand V. Salazar[1], Jessie C. Braganza[1], Mila Fulache-Aligato[1], Mark J. Dating[2], Jason R. Angeles[1], Kaymart A. Gimutao[1], Alvin Tan[1], Regie Baga[3]

[1]Research Institute for Tropical Medicine, Muntinlupa, Philippines, [2]University of the Philippines at Los Banos, Laguna, Philippines, [3]Regional Health Office 2, Cagayan, Philippines

In the Philippines, long lasting insecticidal nets (LLINs) played a major role in reducing malaria burden over the past decade. Out of 83 provinces 74 of them have been declared malaria free with many provinces showing zero malaria cases in the past two to three years. Only eight provinces (Cagayan, Davao del Norte, Maguindanao, Mindoro Occidental, Palawan, Sultan Kudarat, Sulu, Tawi-Tawi) have indigenous malaria cases. With these recent improvements, the program direction shifted from control to sub national elimination with the vision malaria-free country by 2030. Despite the huge investments in the use of LLIN, the information on prolonging its use and efficacy is lacking. Thus, this study addressed issues of attrition, biological efficacy, insecticide residue and physical degradation under villagers conditions. Surveys of 462 households using restrospective questionnaire was conducted to determine attrition. Samples of distributed LLINS at varying age were collected to further determine biological efficacy using field collected *Anopheles flavirostris* following WHO Standard Cone Bioassay. Proportional hole indexes (pHI) based on WHO guidelines were also estimated to assess physical degradation. High pressure liquid chromatography analysis of coded LLIN samples measured insecticide residues. Four LLIN brands (*Dawa Plus 2, Olyset, Permanet 2, Interceptor)* distributed from 2012 to 2015 previously distributed by the National Malaria Control and Elimination Program were collected from study sites (Cagayan and Palawan). Based on the survey, an overall 12% attrition rate was obtained. Around 88% of the current nets are still in good condition and can be used any time. Most (91.08%) LLIN are being used with 93.75% of these bed nets were used the night before the interview. 95.02% of the respondents said that the bed nets are used all year round. Further analysis is being done to understand better association of attrition, community practices, biological efficacy, insecticide residue and physical degradation of LLIN to provide evidence for public health policy makers guidance in achieving maximum benefits on LLIN use.

854

DYNAMICS OF INSECTICIDE RESISTANCE INTENSITY, KNOCKDOWN RESISTANCE (KDR) GENE FREQUENCY AND MECHANISM OF INSECTICIDE RESISTANCE IN ANOPHELES GAMBIAE S.L. ACROSS FIVE ECOZONES OF NIGERIA

Effective malaria control depends heavily on continued pyrethroid susceptibility in *Anopheles gambiae* s.l. in Nigeria. Resistance intensity and mechanisms were determined at multiple collection stations at six sentinel sites within five ecozones of Nigeria. Deltamethrin and DDT susceptibility tests were done on *An. gambiae* s.l. mosquitoes using CDC bioassay method. Polymerase chain reaction (PCR) assays were used for species identification. Resistance intensity and PBO synergist assays were also done using standard methods. The *kdr* genotypes were determined in *An. gambiae* s.l. using allele-specific PCR assays. *An. gambiae* s.l. showed resistance to deltamethrin in four of the five ecozones- rainforest, Guinea, Sudan and the Sahel-savannas. High frequency of deltamethrin resistance was observed in the rainforest (Oyo) with mortality ranging from 16 (95%CI 8.8-23.4) to 36 (95%CI 26.6.-45.4) percent, while in the Sahel savanna (Sokoto) mortality ranged from 69 (95%CI 59.9-78.1) to 77 (95%CI 68.8-85.2) percent. Deltamethrin resistance at 5x and 10x diagnostic concentrations was recorded at three of four collection stations

in the rainforest part of Oyo and at all four stations in the rainforest (Ebonyi). In five sites, piperonyl butoxide (PBO) synergist assays indicated that elevated oxidases are the only contributors to pyrethroid resistance. In the rainforest, additional resistance mechanisms are likely as PBO did not increase mortality to 100%. *Kdr* gene frequencies for deltamethrin-exposed mosquitoes varied slightly across the ecozones with a range of 0.13 in the Guinea savanna to 0.29 in the Sahel savanna; those for DDT-exposed mosquitoes varied from 0.04 in the Sudan-savannah to 0.23 in the Sahel savanna. Higher *kdr* gene frequencies were observed in deltamethrin-exposed than in DDT-exposed mosquitoes in five sentinel sites. This study documents deltamethrin resistance in multiple ecozones of Nigeria with higher intensity resistance in rainforest (Ebonyi and Oyo) sites. Resistance mitigation strategies should be considered for Ebonyi and Oyo and may include distribution of non-deltamethrin, PBO, or next generation LLINs.

855

INSECTICIDAL AND REPELLENT ACTIVITIES OF NATURAL PRODUCT DERIVATIVES FROM THE MADAGASCAN MEDICINAL PLANT *CINNAMOSMA FRAGRANS* AGAINST THE YELLOW FEVER MOSQUITO *AEDES AEGYPTI*

Megha Kalsi[1], Preston Manwill[2], H. Liva Rakotondraibe[2], Peter M. Piermarini[1]

[1]The Ohio State University, Wooster, OH, United States, [2]The Ohio State University, Columbus, OH, United States

New insecticides and repellents are needed to improve control the *Aedes aegypti* mosquito, which is the primary vector of several emerging arboviruses, including Zika, yellow fever, chikungunya, and dengue fever. Recent work by our group has identified a drimane sesquiterpene dialdehyde (cinnamodial: CDIAL) from the Madagascan medicinal plant *Cinnamosma fragrans* that is an agonist of mosquito transient receptor potential A1 (TRPA1) channels and exhibits promising activities as an insecticide and repellent against *Ae. aegypti*. The goal of the current study was to generate insights into CDIAL's insecticidal and repellent activities by screening the bioactivities of several chemical derivatives of CDIAL containing modifications to one or both of its electrophilic aldehyde functions. All of the chemical derivatives exhibited reduced or nominal antifeedant activity (a proxy for TRPA1 modulation and repellency) compared to CDIAL. While most of the derivatives exhibited dramatically weaker insecticidal activity against larvae and adult females of *Ae. aegypti* compared to CDIAL, two compounds retained similar or improved insecticidal activity against larvae compared to CDIAL. The results indicate that the electrophilic aldehyde functions of CDIAL are critical to its activation of TRPA1 and repellent activity, but not its toxicity, which confirms our earlier work suggesting that the toxicity of CDIAL is independent of TRPA1 modulation. Current efforts are developing additional analogs of CDIAL to better understand its structure-activity relationships and mechanism of toxic action on mosquitoes.

856

THE THUMB TEST: A BENCHTOP TEST FOR QUANTIFYING THE EFFECTS OF INSECTICIDE-TREATED NETTING ON MOSQUITO BEHAVIOR

Amy Guy[1], Geraldine Foster[1], Agnes Matope[1], Jim Maas[1], David Towers[2], Hilary Ranson[1], Philip McCall[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]University of Warwick, Coventry, United Kingdom

Long lasting insecticidal nets (LLINs) are essential for malaria control in Africa, but their future is threatened by resistance to pyrethroid insecticides, the primary insecticide class used. To accelerate the screening of potential new chemicals or net types, we developed the 'Thumb Test', a simple benchtop assay to quantify the effects of novel net treatments on mosquito behavior during host seeking, and on survival and a range of sub-lethal effects post-exposure. Bloodfeeding (on the operator's thumb) through the test net can be permitted or prevented, and measurement of detailed behavioral events at the net interface are video recorded (20min) for subsequent analysis to measure events ranging from pre-contact repellency, contact-irritancy and bloodfeeding interference. Individual mosquitoes are used, allowing precise determination of correlations between duration of LLIN contact and the effects of exposure. Testing 4 mosquito strains (2 susceptible, 2 resistant) on untreated net, PermaNet 2 and Olyset LLINs, response rates varied from 13 to 57%; all strains responded, and all would land and bloodfeed through LLINs. Bloodfeeding duration was reduced in all strains on LLINs compared to untreated netting ($P<0.05$): *e.g.* mean bloodmeal duration by Banfora (IR strain) was 8.40 min on untreated net, but 5.03 and 3.55 min on PermaNets and Olysets respectively ($p<0.05$). Post-exposure, survival of resistant mosquitoes was reduced from an average of 14 days after bloodfeeding through untreated nets to less than 9 days on LLINs; when bloodfeeding was prevented, longevity post-exposure of resistant mosquitoes fell from 15 to 8 days on untreated net and LLINs respectively. Further validation is nearing completion and a comprehensive evaluation and standard operating procedure are being developed. The test is simple to operate, inexpensive to install in a basic laboratory setting and generates considerable data per mosquito tested. We present it as a method with significant potential to contribute to the search for novel LLIN treatments and as an addition to the existing WHO test repertoire for evaluating resistance in vector populations.

857

A BASELINE ENTOMOLOGICAL REPORT OF MOSQUITO VECTORS AND INSECTICIDE RESISTANCE IN UGANDA PRIOR TO A LLIN NATIONAL UNIVERSAL COVERAGE CAMPAIGN

Amy Lynd[1], Samuel Gonahasa[2], Ambrose Oruni[1], Catherine Maiteki-Sebuguzi[2], Jimmy Opigo[3], Adoke Yeka[4], Grant Dorsey[5], Sarah G. Staedke[6], Moses R. Kamya[7], Martin Donnelly[1], Janet Hemingway[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]Infectious Diseases Research Collaboration, Kampala, Uganda, [3]Uganda Ministry of Health, Kampala, Uganda, [4]Makerere University School of Public Health, Kampala, Uganda, [5]University of California, San Francisco, CA, United States, [6]London School of Hygiene & Tropical Medicine, London, United Kingdom, [7]Makerere University College of Health Sciences, Kampala, Uganda

Pyrethroid resistance, due to both target site mutations (kdr) and metabolic mechanisms, has been reported across Africa and may threaten malaria control. One approach to overcoming this threat is to combine a pyrethroid insecticide on LLINs with a synergist, piperonyl butoxide (PBO), which is capable of inhibiting cytochrome P450s, and potentially overcoming pyrethroid resistance in anopheline vectors. In Uganda, insecticide resistance mutations were first observed in Anopheles gambiae in 2001, and the problem of resistance has been increasing. Recent data suggest that pyrethroid resistance is now widespread across Uganda and that the causal mechanisms include kdr, cytochrome P450s, carboxylesterases, and glutathione-s-transferases. At least one specific P450 has been reproducibly associated with pyrethroid resistance in Uganda and data suggest that Ugandan-specific resistance markers may explain 50% of the variance seen in pyrethroid resistance. Previous work has demonstrated that insecticide resistance can be very heterogeneous on a fine spatial scale which may not be detected by traditional phenotypic monitoring methods. A cluster-randomised trial designed to evaluate the impact of long-lasting insecticidal bednets (LLINs), with and without PBO, distributed via a national universal coverage campaign in 2017/2018 is underway in 104 clusters (health sub-districts) across 48 districts in Uganda. Since variations in insecticide resistance between clusters could be a major confounder of our primary objective, we undertook a baseline entomological survey across the study site before the universal LLIN distribution campaign. Mosquitoes from 10 randomly selected households in all 104 clusters were collected using prokopack aspirators. Up to 50

Anopheles gambiae s.l. per cluster were investigated for Ugandan-specific resistance markers to obtain cluster specific estimates of resistance. We present the results of these baseline entomological and genotype resistance surveys and discuss their implications.

858

INTENSITY OF PYRETHROID RESISTANCE IN ANOPHELES GAMBIAE S.L. IN THE DEMOCRATIC REPUBLIC OF CONGO

Fiacre Agossa[1], Francis Wat'senga[2], Emile Zola Manzambi[2], Gillon Illombe[2], Tania Mapangulu[2], Tamfum Muyembe[2], Mame Niang[3], Christen Fornadel[4], Ferdinand Ntoya[5], Richard Oxborough[1], **Seth Irish**[3]

[1]PMI VectorLink project, Abt Associates, North Bethesda, MD, United States, [2]Institut National de Recherche Biomédicale, Kinshasa, Congo, Democratic Republic of the, [3]President's Malaria Initiative and Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]President's Malaria Initiative and United States Agency for International Development, Arlington, VA, United States, [5]Pr4. President's Malaria Initiative, United States Agency for International Development, Kinshasa, Congo, Democratic Republic of the

Pyrethroid resistance is an important concern of the National Malaria Control Program in the Democratic Republic of Congo (DRC), as pyrethroid-treated bed nets are the primary malaria vector control intervention used in the country. Resistance monitoring has revealed widespread resistance, but it is unknown to what extent this resistance is compromising control efforts. Measuring the intensity of resistance may improve our understanding of operationally significant resistance. The intensity of resistance of *Anopheles gambiae* s.l. was monitored in Kinshasa in 2016 and 2017, and in 6 sites throughout the country in 2017. CDC bottle bioassays using one, two, five, and ten times the diagnostic dose of permethrin and deltamethrin were conducted using *An. gambiae* s.l. collected as larvae. One round of these assays were conducted at 5 sites in and around Kinshasa province in 2016 six months prior to a distribution of deltamethrin treated bednets in Kinshasa province in December 2016. Three subsequent rounds of intensity assays were then conducted 2, 6, and 10 months after the distribution to monitor changes in the intensity of resistance. In the sites outside of Kinshasa, a single round of intensity assays was conducted in 2017. Resistance to deltamethrin and permethrin was noted in all sites at all time points. In Kinshasa, resistance to permethrin was intense: survival was 16-100% and 0-95% when mosquitoes were exposed to 5 and 10x the diagnostic dose, respectively. Resistance to deltamethrin was less intense: survival was 0-74% and 0-23% when mosquitoes were exposed to 5 and 10x the diagnostic dose, respectively. The results from the six sites tested outside of Kinshasa showed similar patterns, with 64-90% and 20-84% surviving 5 and 10x permethrin exposure, and 0-39% and 0-20% surviving 5 and 10x deltamethrin exposure, respectively. Pyrethroid resistance is a pressing issue for malaria control which threatens the gains made in the past ten years of scaling up vector control in DRC. Monitoring of the intensity of insecticide resistance should continue; there may be a need to consider distribution of next generation nets (PBO nets, bi-treated nets).

APPLICATION OF A NOVEL MULTIPLEX ASSAY TO ASSESS ANOPHELES MALARIA TRANSMISSION ECOLOGY IN THE CENTRAL HIGHLANDS OF MADAGASCAR

Riley E. Tedrow[1], Joclyn Ratovonjato[2], Arsene Ratsimbasoa[2], Edward Walker[3], Peter A. Zimmerman[1]

[1]Case Western Reserve University, Cleveland, OH, United States, [2]Direction de la Lutte contre le Paludisme, Antananarivo, Madagascar, [3]Michigan State University, East Lansing, MI, United States

Due to variability in mosquito habitat preference, feeding patterns, and susceptibility to various measures of insect control; it is vital that we efficiently characterize the vector's bloodmeal. Using field-collected *Anopheles* mosquitoes from two villages in the highlands of Madagascar in December 2017, we designed and utilized a novel Ligase Detection Reaction and Fluorescent Microsphere Assay to efficiently identify the mosquito, query the mammalian host, and test for the presence of malaria parasites. We collected the following species using a combination of pyrethroid spray catch and barrier screens: *A. arabiensis* (8), *A. coustani* (164), *A. funestus* (11), *A. gambiae* (14), *A. maculipalpis* (96), *A. rufipes* (85), *A. squamosus* (87), and six specimens of an unknown *Anopheles* species. There was an overall concordance of 82% between LDR-FMA and morphologically identified specimens. This assay successfully detected multiple hosts in the blood, revealing a high zoophilic trend in the sample, even amongst traditionally anthropophagic species. Furthermore, numerous mosquitoes were *Plasmodium* positive: 2.6% *P. falciparum*, 4.8% *P. vivax*, 0.8% *P. malariae*, and 1.2% *P. ovale*; 31.4% of which constituted mixed-species infections. Finally, we briefly discuss a potentially novel *Anopheles* mosquito capable of harboring *Plasmodium* parasites. This multiplex assay enables efficient characterization of large mosquito samples and simultaneous pathogen detection to monitor and incriminate disease vectors in Madagascar. Furthermore, it provides valuable insight into mosquito transmission ecology in a region dominated by submicroscopic infection, a potential barrier to the ultimate goal of total malaria eradication.

BEHAVIORS AND MOLECULAR IDENTIFICATION OF *ANOPHELES* SPECIES IN KARAMA, WEST SULAWESI, INDONESIA

Jenna R. Davidson[1], Isra Wahid[2], Rusdiyah Sudirman[2], Victoria Makuru[1], Allison L. Hendershot[1], Timothy A. Burton[1], Honglin Xiao[1], Xiaoyu Yu[1], Emma Troth[1], Stephanny Lizarraga[1], Din Syafruddin[3], Puji Asih[3], Neil F. Lobo[1]

[1]University of Notre Dame, Notre Dame, IN, United States, [2]Department of Parasitology, Faculty of Medicine, Hasanuddin University, Makassar, Indonesia, [3]Eijkman Institute for Molecular Biology, Jakarta, Indonesia

Information regarding local malaria vector compositions in association with their bionomic traits is vital for targeting susceptibilities in mosquito behaviors and implementing effective malaria interventions. Many studies rely on morphological identification of mosquitoes, limiting identification to visually distinct species. Sulawesi, Indonesia is a region with high species diversity, with previous documentation of eight malaria vectors and species complexes. However, vector molecular identification, distribution, ecology, and vector behaviors have not been well characterized in West Sulawesi, Indonesia. Mosquitoes were collected in Karama, Indonesia a village located in the northwestern regency Mamuju, West Sulawesi using human-landing collections, barrier screens, barrier screens with eaves, and kelambu traps. Mosquitoes were morphologically typed and then molecularly distinguished based on ribosomal DNA ITS2 and mitochondrial DNA CO1 sequences. Collection methods were evaluated and compared based on morphological and molecular identities. The presence of *An. barbirostris subgroup clade V* in West Sulawesi, Indonesia in confirmed here for the first time. While morphological identifications recognized 19 species, 16 distinct species groups were identified through molecular analyses. Of the 16, six could not be identified through comparison to published sequences. Peak activity times for molecularly identified *An. barbirostris* and *An. vagus* indicated activity in first half of the night. Kelambu traps collected the most Anopheles species (n=14) as well as the highest frequency of Anopheles (n=2,924). Morphological identification of secondary vectors in this study was generally inaccurate, underlining the importance of using molecular analysis in conjunction with morphological investigations. Collection methods indicated certain biases that can be tailored to future entomological studies. Detailed knowledge about primary and secondary malaria vectors and bionomic characteristics that effect malaria transmission and intervention effectiveness are central in the pursuit of malaria elimination.

861

CHARACTERIZATION OF RIBOSOMAL DNA OF ANOPHELES FLUVIATILIS SPECIES T AND U FROM A SYMPATRIC POPULATION

Gunjan Sharma, Om Prakash Singh

National Institute of Malaria Research, Delhi, India

Anopheles fluviatilis sensu lato is a vector of primary importance responsible for malaria transmission in forest and foothills of India. Provisionally this species was recognized as a member of four sibling species—species S, T, U and V, identifiable based on the chromosomal inversions present on chromosome 2 and 3. However recently based on the genetic barcode of three members of species complex, i.e., S, T and U, these nominal species were made conspecific. To resolve this issue, we characterized a stretch of partial ribosomal DNA (rDNA) of two sympatric species, species T and U, encompassing from 5.8S rDNA to D3 domain of 28S rDNA. PCR products were amplified from individual mosquitoes using a single PCR (1.75 kb) and sequenced through primer-walking. Analysis of sequences revealed four unique nucleotide locus where fixed differences exist between species T and U. Since these differences are species-specific and fixed in a sympatric population, our data disapprove the synonymy status of species T and U.

862

SIBSHIP RECONSTRUCTION REVEALS RELATIONSHIPS BETWEEN LARVAL ABUNDANCE AND OVIPOSITION BEHAVIOR WITHIN AND AMONG ANOPHELES ARABIENSIS HABITATS

Joel Odero[1], Ulrike Fillinger[1], David Weetman[2]

[1]Malaria Programme, International Centre for Insect Physiology and Ecology, Nairobi, Kenya, [2]Vector Biology Department, Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Strategies to control malaria vectors at the larval stage appear increasingly important with acknowledgement of the limitations of primary interventions which target only adults biting and resting indoors. Larviciding strategies would benefit from knowledge on habitat productivity and the proportions of female mosquitoes that oviposit at multiple breeding sites to allow improved targeting. To investigate these questions, we applied genetic markers to *Anopheles arabiensis* larval samples from artificial and natural ponds to investigate relatedness within and among habitats. In a controlled experiment, 18 artificial ponds were left uncovered for 4 days to allow oviposition by wild females, then covered for a further 6 days to prevent further egg laying; larvae were sampled daily from day 5. Additionally, *Anopheles* natural habitat categories, 'puddles' and 'drainage ditches', were identified and larvae sampled. The larvae were identified to species and *An. arabiensis* samples genotyped using microsatellites. We used BAPS and COLONY softwares, to provide methodologically-independent reconstructions of sibling groups. In the ponds, COLONY (which is widely used but known to artificially partition large families) identified more families than BAPS but results were well correlated (r=0.7). In both cases the number of families predicted the total number of larvae ($r^2 \approx 0.5$), supporting our hypotheses that more larvae result from more females laying rather than simply better survival of an equivalent number of families. From BAPS results, 64% of females had deposited larvae in multiple ponds and from COLONY, 45%, suggesting a high frequency of skip oviposition behaviour. In the natural habitats, the number of families strongly predicted larval abundance ($r^2 \approx 0.8$) and this relationship did not differ between habitat types (P=0.19), with an overall average of 2.4±0.84 larvae per family. The sharing of habitat by multiple females and high skip-oviposition rate shown here are favorable for the success of an autodissemination approach for larval control and may be a factor in maintenance of high genetic diversity in *An. arabiensis* populations.

863

CONSTRUCTION OF THE EFFICIENT GENOMIC EDITING SYSTEM WITH CRISPR/CAS9 IN VECTOR MOSQUITO, *AEDES ALBOPICTUS*

Tong Liu, Wenqiang Yang, Yugu Xie, Peiwen Liu, Lihua Xie, Jinbao Gu, Kun Wu, Guiyun Yan, **Xiao-Guang Chen**

Southern Medical University, Guangzhou, China

Aedes(Stegomyia)albopictus , also known as Asian tiger mosquito, is a mosquito originally inhabiting in the countries of Asia but becoming more and more emerging throughout the world recent years. It can transmit several arboviruses including Dengue, Zika and Chikungunya virus, which already becomes a public health threat. Nowadays, genetic control is one of the most promising methods for mosquito population suppression. However, there is little research in gene editing of *Ae. albopictus*. In the present study, we first employed two genes, kynurenine hydroxylase and dopachrome conversion enzyme, to generate germ-line mutations by CRISPR/Cas9 system. Following Cas9-sgRNA RNPs injection into pre-blastoderm embryos, 30–50% of fertile survivors produced alleles that failed to complement existing *kh* and *yellow* mutation. We conclude that CRISPR/Cas9-mediated gene editing system is accomplishable in *Ae. albopictus*, offering an efficient tool for gene editing in mosquito population management. Moreover, our study represents a step toward

the application of large scale, species-specific population control technologies targeting *Ae. albopictus* that rely on Cas9-based gene drive mechanisms.

864

PHYLOGEOGRAPHIC RELATIONSHIPS AND GENE FLOW PATTERNS OF GLOBAL COLLECTIONS OF AEDES AEGYPTI (DIPTERA: CULICIDAE) BASED UPON THE MITOCHONDRIAL CYTOCHROME C OXIDASE SUBUNIT 1 GENE

Sachini D. Fernando[1], Menaka Hapugoda[2], Rushika Perera[3], William C. Black IV[3], Nissanka K. De Silva[1]

[1]University of Sri Jayewardenepura, Nugegoda, Sri Lanka, [2]University of Kelaniya, Ragama, Sri Lanka, [3]Colorado State University, Fort Collins, CO, United States

The phylogeographic relationships among global collections of the mosquito *Aedes aegypti* was evaluated using 143 sequences from the mitochondrial Cytochrome C Oxidase 1 gene (CO1) including fourteen new sequences from Sri Lanka. The BEAST2 analysis implementing a CO1 arthropod molecular clock estimated that *Ae. aegypti* arose as a species ~614 thousand years ago (kya) in the late Pleistocene, which gave rise to two lineages. At 545 kya an "early" East African clade and at 372 kya an East African "late" clade arose. The "early" East African clade gave rise to three lineages, one of which is distributed throughout all tropical and subtropical regions, a second that contains Southeast Asian/Sri Lankan mosquitoes and a third that contains mostly New World mosquitoes. West African collections were not represented in this early clade. The "late" East African clade gave rise to East and West lineages. This late clade continues to differentiate throughout Africa which eventually gave rise to branches that spread globally. A Bayesian analysis of migration rates suggested abundant gene flow between India/Pakistan and the rest of the world and high rates of gene flow between East and West Africa and between Sri Lanka and Southeast Asia. This may reflect commercial movement of mosquitoes given the location of Sri Lanka along the key shipping route between the Malacca Straits and the Suez Canal and the fact that Sri Lanka contains some of the busiest harbors and ports in the region.

865

A TRANSCRIPTOMIC APPROACH TO IDENTIFY MOSQUITO TARGETS FOR BLOCKING PLASMODIUM VIVAX AND PLASMODIUM FALCIPARUM TRANSMISSION

Majoline T. Tchioffo[1], Marlene Jessy Goupeyou[2], Nicolas Puchot[1], Caroline Proux[3], Etienne Kornobis[4], Ousmane Ndiath[5], Catherine Bourgouin[1]

[1]GFMI, Institut Pasteur of Paris, Paris, France, [2]IMI, Institut Pasteur of Madagascar, GFMI, Institut Pasteur of Paris, Paris, France, [3]PF2, Institut Pasteur of Paris, Paris, France, [4]Bio-informatic , Institut Pasteur of Paris, Paris, France, [5]G4 Malaria Group, Institut Pasteur of Madagascar, Antananarivo, Madagascar

Plasmodium falciparum and *Plasmodium vivax* are responsible for the majority of malaria cases worldwide. Whereas *P. falciparum* interactions with its mosquito vectors has been the focus of many studies, little is known on the interactions of *P. vivax* with its vectors. We capitalized on the peculiar situation of Madagascar where both parasite species are prevalent along with the most studied mosquito vectors: *Anopheles gambiae* and its sister taxa *Anopheles arabiensis*. After establishing a field laboratory, we infected local *An. arabiensis* mosquitoes with *P. falciparum* and *P. vivax*. Midguts from infected mosquitoes were collected and processed for a comparative RNAseq analysis to identify common or unique pathways to both/each parasite species and to better understanding the specificity of the interaction between each parasite species and their common vector, *An. arabiensis*. Preliminary results of this RNAseq analysis will be presented and discussed.

866

GENOME-WIDE ASSOCIATION STUDY IDENTIFIES GENES UNDERLYING DENGUE VIRUS SUSCEPTIBILITY IN WILD-TYPE *AEDES AEGYPTI* FED ON VIREMIC HUMAN BLOOD

Laura B. Dickson[1], Albin Fontaine[1], Sarah H. Merkling[1], Benjamin R. Evans[2], Andrea Gloria-Soria[2], Mo Li[2], Xiaoqing Yu[2], Kuang-Yao Lee[2], Lauren B. Carrington[3], Cameron P. Simmons[4], Hongyu Zhao[2], Jeffrey R. Powell[2], Louis Lambrechts[1]

[1]Pasteur Institute, Paris, France, [2]Yale University, New Haven, CT, United States, [3]Oxford University Clinical Research Unit, Ho Chi Minh City, Viet Nam, [4]Monash University, Monash, Australia

Natural populations of *Aedes aegypti* mosquitoes vary in their susceptibility to dengue virus (DENV) infection but the underlying genetic basis has not been elucidated. Although single nucleotide polymorphisms (SNPs) in genetic markers as well as expression of certain genes have been linked to variation in DENV susceptibility, the *Ae. aegypti* genes containing causative polymorphisms are unknown. In this study, we performed a genome-wide association study (GWAS) followed by gene-silencing assays to identify *Ae. aegypti* genes functionally involved in natural DENV susceptibility. Wild mosquitoes collected in Ho Chi Minh City, Vietnam were tested for DENV susceptibility within three generations of colonization in the laboratory. They were scored for DENV infection after experimental exposure to DENV viremic blood by feeding directly on naturally infected dengue patients. Genomic polymorphisms associated with DENV infection status were identified using a recently developed *Ae. aegypti* SNP chip with genome-wide distribution. A shortlist of candidate genes located near SNPs significantly associated with DENV infection status is currently being tested by RNAi-mediated gene knockdown *in vivo*. Knockdown of one candidate gene resulted in a significant increase of DENV infection prevalence, indicating an antiviral function. Further characterization of this gene and other shortlisted candidates is ongoing. Our study is the first GWAS in wild-type *Ae. aegypti* that identifies candidate genes associated with DENV susceptibility that are subsequently validated at the functional level. Our results contribute to elucidate the genetic basis of natural DENV susceptibility in *Ae. aegypti* and will provide target genes that could be manipulated in future *Ae. aegypti* genetic control strategies.

867

INSIGHTS INTO GENOMIC, CHROMOSOMAL AND ECOLOGICAL DIFFERENTIATION OF THE MALARIA MOSQUITO ANOPHELES MESSEAE SENSU LATO

Maria V. Sharakhova[1], Anastasia N. Naumenko[1], Dimitriy A. Karagodin[2], Andrey I. Yurchenko[3], Mikhail I. Gordeev[4], Anton V. Moskaev[4], Elina M. Baricheva[2], Igor V. Sharakhov[1]

[1]Virginia Tech, Blacksburg, VA, United States, [2]Institute of Cytology and Genetics, Novosibirsk, Russian Federation, [3]Institute of Biodiversity Animal Health and Comparative Medicine, Glasgow, United Kingdom, [4]Moscow Regional University, Moscow, Russian Federation

A dominant malaria vector *Anopheles messeae sensu lato* (*s.l.*) is a highly polymorphic species with a wide geographic distribution throughout Eurasia. Five highly polymorphic inversions associated with geographical distribution of the species have been reported. A sister species, *An. daciae,* was discriminated from *An. messeae sensu stricto* (*s.s.*), further referred as *An. messeae,* based on five fixed nucleotide substitutions in the Internal Transcribed Spacer 2 (ITS2) of ribosomal DNA. However, genome-wide genetic divergence and chromosomal differentiation between two species remained unexplored. In this study, we analyzed ITS2 sequences and karyotypes in 289 larvae specimens of *Anopheles* from three locations in Moscow region. Five individual genomes for each species were sequenced. Our study determined five previously described fixed substitutions in ITS2 of *An. messeae* whereas the ITS2 sequence in *An. daciae* had both *An. messeae* and *An. daciae* variants present simultaneously in the first three positions of each individual. Fixed differences between *An. messeae* and

An. daciae were found only in the last two positions. Only one mosquito was identified as a hybrid between *An. messeae* and *An. daciae* based on heterogeneous substitutions in all five positions. Our genome sequence comparison has demonstrated the genome-wide divergence between the two species. The divergence was extremely high on the X chromosome. A cytogenetic comparison of *An. messeae* and *An. daciae* samples demonstrated that two species significantly differ from each other by the frequencies of the polymorphic inversions. Inversion X1 was fixed in *An. messeae* but was polymorphic in all *An. daciae* populations. Frequencies of 3 polymorphic autosomal inversions were higher in *An. messeae* than in *An. daciae.* Each of the populations had distinct species composition suggesting different ecological preferences of the two species. Thus, our study revealed the high level of genetic differentiation between *An. messeae* and *An. daciae* in Moscow region. The research was supported by the Russian Science Foundation grant No 15-14-20011 to I.V.S. and RFBR grant No 18-04-01117A to M.I.G.

GENETIC VARIATION IN CULEX TARSALIS ASSOCIATED WITH BLOODMEAL HOST CHOICE

Bradley J. Main[1], Tara C. Thiemann[2], C. Titus Brown[1], Christopher M. Barker[1]

[1]UC Davis, Davis, CA, United States, [2]University of the Pacific, Stockton, CA, United States

Culex tarsalis is the principal vector of several human pathogens in the western United States, including West Nile (WNV), western equine encephalomyelitis, and St. Louis encephalitis viruses. Of these, WNV causes the greatest annual disease burden, and incidence of WNV disease is highest in areas where *Cx. tarsalis* is the predominant vector, such as the northern Great Plains and California's Sacramento Valley. Because of its status as an important bridge vector of zoonotic arboviruses, the ecology of *Cx. tarsalis*, including feeding behavior, has received significant research attention, but genetic studies are limited, perhaps due in part to the lack of a reference genome. Genetically distinct populations have been identified in the US using microsatellite markers, but they have not been characterized regarding phenotypic differences such as vector competence, insecticide resistance, or host-seeking behavior. In this study, we hypothesized that ornithophilic and opportunistic genotypes of *Cx. tarsalis* occur in sympatry and the relative abundance of these genotypes influences the frequency of overall mammalian blood meals. To test this, we sequenced 40 blood-fed adult *Cx. tarsalis* females, including 13 that fed on mammals, 2 that fed on reptiles, and 24 that fed on birds. In addition, we deep-sequenced one female mosquito from an inbred colony (Kern County, CA) and assembled a draft reference genome using SPAdes (v3.11) and MEGAHIT (v1.1.2). Due to inadequate reference assembly quality (N50=1789), we performed a preliminary analysis on the mitochondrial genome (15,566bp). A principal components analysis based on 1,044 mitochondrial SNPs revealed evidence for population structure among *Cx. tarsalis* collected from the same site in Davis, CA. We also observed a lower nucleotide diversity among mammal-fed (pi=0.001) versus bird-fed (pi=0.002) *Cx. tarsalis*. This pattern is consistent with the hypothesis that particular genotypes are more likely to feed on mammalian hosts.

869

EFFECTS OF FOREST LANDSCAPE ANTHROPIZATION AND LAND-USE AND LAND-COVER CHANGE ON THE ECOLOGY OF *AEDES* ARBOVIRUS VECTORS IN LARGE INDUSTRIAL PALM AREAS, CÔTE D'IVOIRE

Julien B. Zahouli[1], Benjamin G. Koudou[2], Pie Müller[3], David Malone[4], Yao Tano[5], Jürg Utzinger[3]

[1]Centre Suisse de Recherches Scientifiques en Côte d›Ivoire, Abidjan, Côte D›Ivoire, [2]Centre for Neglected Tropical Diseases, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]Swiss Tropical and Public Health Institute, Basel, Switzerland, [4]Innovative Vector Control Consortium, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [5]Unité de Formation et de Recherche Biosciences, Université Félix Houphouët-Boigny, Abidjan, Côte D'Ivoire

In Cote d'Ivoire, forest landscape anthropization (FLA) and land-use and land-cover (LULC) change have been associated with a tangential transmission of zoonotic *Aedes* mosquito-borne arboviruses to humans. We assessed the effects of FLA and LULC change on *Aedes* ecology in large industrial palm areas in yellow fever (YF) and dengue (DEN) foci. From January 2013 to December 2014, *Aedes* eggs, larvae and adults were sampled across a gradient of FLA (sylvatic, peridomestic and domestic ecozones), and four land-covers (Forest, polyculture, palm monoculture and housing area) using ovitraps, larval surveys and human-baited double-net traps. In total, 28,276 *Aedes* specimens belonging to 11 species (*Ae. aegypti*, *Ae. africanus*, *Ae. dendrophilus*, *Ae. fraseri*, *Ae. furcifer*, *Ae. lilii*, *Ae. luteocephalus*, *Ae. metallicus*, *Ae. opok*, *Ae. palpalis* and *Ae. vittatus*) were found. *Aedes* species richness (7 species) and abundance (1.36 ± 0.14 *Aedes*/ovitrap/week) were higher in peridomestic ecozone. *Ae. aegypti* proportion was higher in domestic (81.0%), followed by peridomestic (62.6%) and sylvatic (37.3%) ecozones. Only four *Ae. aegypti* specimens were found in palm monoculture. *Aedes* showed higher species richness in forest (11 species), and higher abundance in polyculture (n = 28,276; 60.9%). *Ae. aegypti*, *Ae. dendrophilus* and *Ae. vittatus* biting rate was 34.6 and 7.2-fold higher in polyculture (21.5 bites/person/day (b/p/d)) and housing area (4.5 b/p/d), respectively, compared to forest (0.6 b/p/d). *Ae. aegypti* displayed strong anthropophagy inflicting 93.0% of bites to humans. *Aedes* biting activity showed bimodal daily feeding cycles, with stronger magnitude in polyculture. Conclusion, FLA and LULC change strongly drive *Aedes* ecology leading to the migration and proliferation of forest-dwelling zoophagic and anthropophagic vectors primarily biting humans in peridomestic ecozone, housing area and polyculture. This may link enzootic to epizootic and epidemic cycles of arboviruses thus raising the risk of transmission of YF and DEN viruses from wild animals to humans around their homes and farms. There is a need for an integrated vector management.

870

INSECTICIDE SUSCEPTIBILITY AND ROLE OF *AN MELAS* IN AN AREA OF MALARIA RESIDUAL TRANSMISSION IN SENEGAL

Ousmane Sy[1], Elhadji Amadou Niang[1], David Weatman[2], Lassana Konaté[1], Ousmane Faye[1], Martin Donnelly[2], Oumar Gaye[1]

[1]UCAD, Dakar, Senegal, [2]LSTM, UK, United Kingdom

Background: The global decrease of malaria incidence in Senegal has changed the disease epidemiology; with malaria occurring mainly in hot spot of residual transmission. *An. melas* is one of the member of the *An. gambiae* s.l. complex found in brackish environment of the country, where its display high density. Despite its known role as secondary/focal malaria vector, little is known about the bionomic of *An. melas,* including as its susceptibility to insecticides. In the context of malaria elimination, it is therefore vital to evaluate the role of *An. melas* in the transmission as well as and its susceptibility to insecticides currently in use in malaria hot-spot areas. **Methods**: The study villages were chosen in the coastal zone in the Saloum River Delta. The malaria vector populations dynamics was monitored using the human landing catches (HLC) and pyrethrum spray catches (PSC) methods. **Results**: During the first study year, a total of 1933 Anopheles specimens (HLC = 700 and SPC =1293) were collected. *An gambiae* s.l. (95% ; n= 1892) was the dominant anopheline species . The molecular identification of members of the Gambiae complex and the search for the infection of the vectors collected are being carried out for the determination of the involvement of the different species in the residual transmission. Susceptibility tests to the WHO-approved insecticides, carried out in adults of *Anopheles gambiae* s.l. collected from brackish water showed that resistant to permethrin (91.3%), but fully susceptibility to organophosphate (100%) and carbamate (100%). **Conclusion and perspective:** This study ongoing shoud provide an up-to-dated information of the level of involvement of *An. melas* in malaria

transmission and its status of insecticide suceptibility in an area of malarial transmission hot-spot. These data are essential for targeted vector control interventions to achieve elimination goal in Senegal. Mots clés: Malaria, Transmission résiduelle, *An melas*, insecticide susceptibility, Sénégal.

871

WIDE DISTRIBUTION OF THE MAYARO VIRUS VECTOR HAEMAGOGUS SPECIES IN TRINIDAD, WEST INDIES

Renee Ali[1], Adesh Ramsubhag[1], Azad Mohammed[1], Jayaraj Jayaraman[1], Naresh Nandram[2], Diosany Raul Lezcano[3]

[1]University of the West Indies, St. Augustine, Trinidad and Tobago, [2]Insect Vector Control Divison, Ministry of Heatlh, Cunupia, Trinidad and Tobago, [3]Insect Vector Control Divison, Ministry of Health, Cunupia, Trinidad and Tobago

Emerging mosquito borne diseases have posed a major challenge to public health systems in many regions of the world within recent time. The Mayaro Virus (MAYV) is an emerging mosquito borne disease that was first reported in the island of Trinidad in 1954, but is now known to be endemic to Central and South America. This virus is only known to cause sporadic cases and limited outbreaks, but may have the potential to develop into a major epidemic in the future. The primary vector for MAYV is Haemagogus which is also the vector for the yellow fever virus, is also endemic to the region. Managing any possible future MAYV epidemic will require knowledge on the distribution of the vector. The last survey for *Haemagogus* in the island of Trinidad was in 1995, when the vector was reported to be confined to the Northwestern peninsula. The current study aims to update the distribution of Haemagogus in this island. A survey for the vector was conducted over the period March 2017 to March 2018. Adult mosquitoes were collected off human bait during 60 trips to major forested areas in the island . Larvae were also collected after breeding in tyre traps from all sites sampled. The results show that Haemagogus is now widely distributed in the island, with a total of 155 pools of the mosquito collected from all five zones surveyed. The average density of adult mosquitoes collected during the wet season (June-November) was six times the amount collected in the dry season (December-May). The species collected included Hg. janthinomys , Hg. equinus , Hg Leucocelaneus and Hg. celeste. Hg. janthinomys was the most adaptive species, which was found in all zones and accounted for eighty-eight percent of mosquitoes collected in the survey. Hg. janthinomys was predominantly found in the Ramsar site Caroni swamp and surrounding villages. This mangrove wetland serves as a habitat for a number of birds and wild mammals, but not primates which are known to be the main reservoir in sylvatic cycle of the MAYV. These new findings have significant epidemiological implications for the sylvatic cycle of this medically important species.

872

CATTLE ODOR IS A POWERFUL ATTRACTANT FOR EXOPHAGIC MALARIA VECTORS

Bernard O. Abong'o[1], Xiaoyu Yu[2], Martin Donnelly[1], Martin Geier[3], Gabriella Gibson[4], John Gimnig[5], Feiko ter Kuile[1], Neil Lobo[2], Eric Ochomo[6], Maurice Ombok[6], Aaron Samuels[7], Stephen J. Torr[1], Frances M. Hawkes[4]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]University of Notre Dame, Notre Dame, IN, United States, [3]Biogents AB GmbH, Regensburg, Germany, [4]University of Greenwich at Medway, Chatham Maritime, United Kingdom, [5]Centers for Disease Control and Prevention, Atlanta, GA, United States, [6]Kenya Medical Reserch Institute, Kisumu, Kenya, [7]Centers for Disease Control and Prevention -Kenya Medical Research Institute, Kisumu, Kenya

Background: As currently implemented, malaria vector surveillance in sub Saharan Africa uses tools that are mostly able to target endophagic and endophilic mosquitoes leaving exophagic blood seeking and feeding behaviour largely undescribed. We evaluated the recently developed Host Decoy Trap (HDT) and compared it to the gold standard, Human Landing Catch (HLC), in western Kenya. HLCs are favoured because they elicit a more natural range of *Anopheles* biting-behaviour compared to other sampling tools, and therefore, in principle, provide the most reliable profile of the biting population. The HDT incorporates the main host stimuli that attract blood meal seeking mosquitoes and can be baited with the odours of live hosts. **Results:** Mosquito numbers and species diversity varied significantly between HLCs and HDTs baited with human (HDT-H) or cattle (HDT-C) odour, revealing important differences in behaviour of *Anopheles* species. Significantly higher proportions of *An. arabiensis* were caught in HDT-Cs, 0.94 ± 0.01 and HDT-Hs, 0.76 ± 0.09 than in HLCs, 0.45 ± 0.05 per trapping night. The proportion of *An. gambiae s.s.* was highest in HLC (0.55 ±0.05) followed by HDT-C (0.20 ± 0.09) and least in HDT-C (0.06 ± 0.01). An unbaited HDT placed beside corralled cattle overnight caught mostly *An. arabiensis* with proportions of 0.97 ± 0.02 and 0.8 ± 0.2 in presence and absence of cattle respectively and a mean of 10.4 (2.0-55.0) *Anopheles*/night near cattle, compared to 0.4 (0.1-1.7) *Anopheles*/night in an unbaited HDT indicating that the HDT can be effective without the need for directed odour. **Conclusions**: The capability of HDTs to combine host odours, heat and visual stimuli to simulate a host provide the basis of a system to sample human- and cattle-biting mosquitoes. HDT-C is particularly effective for collecting *An. arabiensis* outdoors. The HDT offers the prospect of a system to monitor and potentially control *An. arabiensis* and other outdoor-biting mosquitoes more effectively.

ENVIRONMENTAL CHARACTERISTICS OF NYSSORHYNCHUS DARLINGI BREEDING SITES AND SPATIOTEMPORAL RELATIONSHIP WITH MALARIA CASES IN 8 VILLAGES IN PERI-IQUITOS, AMAZONIAN PERU

Catharine Prussing[1], Marlon P. Saavedra[2], Sara A. Bickermith[3], Marta Moreno[4], Freddy Alava[5], Mitchel Guzmán[2], Gabriel Carrasco-Escobar[6], Paulo Cesar Valverde[6], Dionicia Gamboa[6], Joseph M. Vinetz[4], Jan E. Conn[3]

[1]SUNY University at Albany, Albany, NY, United States, [2]Universidad Peruana Cayetano Heredia, Iquitos, Peru, [3]Wadsworth Center, New York State Department of Health, Slingerlands, NY, United States, [4]University of California San Diego, San Diego, CA, United States, [5]Ministry of Health, Iquitos, Peru, [6]Universidad Peruana Cayetano Heredia, Lima, Peru

Due to its propensity to bite and rest outdoors, *Nyssorhynchus darlingi*, the major malaria vector in Latin America, is unlikely to be completely controlled by traditional vector interventions such as long-lasting insecticidal nets and indoor residual spraying. Therefore, alternative control measures, such as larval source management (LSM), should be considered. A previous study in the peri-Iquitos region of Amazonian Peru found *Ny. darlingi* larvae presence to be associated with lower forest cover level, proximity to humans, and algae. In Brazil, *Ny. darlingi* breeding sites have been associated with the edges of deforested areas and with man-made water bodies, such as fish ponds and microdams. No recent published studies have characterized the larval habitat of *Ny. darlingi* in peri-Iquitos. From 2016-2017, we sampled 88 water bodies in 8 villages in peri-Iquitos for *Nyssorhynchus* larvae and recorded environmental and chemical characteristics, conducting 5-6 collections per water body. We collected 750 *Ny. darlingi* from both natural and artificial breeding sites. Similar to previous studies, the presence of *Ny. darlingi* was associated with lower enhanced vegetation index (EVI) and more people living within 100m of the water body. Additionally, *Ny. darlingi* presence was associated with the presence of grass and amphibians, lower light intensity (lux), increased cloud cover, and the presence of non-*Ny. darlingi Nyssorhynchus* and *Anopheles* larvae. Houses in the study villages in which inhabitants were diagnosed with malaria during the study period were located closer to *Ny. darlingi*-positive water bodies than houses in which no one was diagnosed with malaria, suggesting that LSM targeting *Ny. darlingi* breeding sites could be an effective control method in this region. This was a pilot study intended to provide preliminary data about the characteristics of *Ny. darlingi* breeding sites in the study villages. Future studies involving more

intensive sampling in these villages will provide a more comprehensive determination of the signature of water bodies that would be the most appropriate targets for LSM.

874

USING SWARM INTELLIGENCE TO SIMULATE MOSQUITO BEHAVIOR AGAINST SPATIAL REPELLENTS

Guofa Zhou, Guiyun Yan, Solomon Kibret

University of California at Irvine, Irvine, CA, United States

Swarm intelligence is a method that deals with collective behavior of individuals that coordinate using decentralized control and self-organization. In natural system, examples of swarm behaviors include ants colonization, fish schooling, etc.. Male mosquitoes are known to exhibit swarm behavior, i.e., males aggregate over specific and conspicuous swarm markers to attract females and repeatedly at the same places over time. Similarly, female mosquitoes are attracted to humans or certain attractant odors, or are repelled by repellent. The aim of this study is to determine if pyrethroid resistant *Anopheles gambiae* mosquitoes behavior differentially from susceptible mosquitoes when against repellents. We used particle swarm optimization (PSO) approaches under the laboratory and MalariaSphere settings. In the laboratory setting, we used 3D tracking system to track the mosquitoes' movement under three conditions: nothing, attractant, and repellent. In the greenhouse setting, we used mark-release-recapture experiments. Both laboratory and greenhouse experiments are ongoing. In the simulation, we assumed a constant release and both attractant and repellent chemicals diffused randomly and omnidirectional in the cubic cage. The velocity component in the PSO was modified by an attraction/repulsion rate and concentration. Simulation result indicated that without attractant/repellent, mosquitoes might fly anywhere clueless. In the presence of attractant odor, all mosquitoes were attracted to the source of the odor. For the repellent, mosquito behavior depends on repellency property of the repellent and mosquito insecticide resistance status. For insecticide susceptible mosquitoes, simulation found that all mosquitoes were eventually repelled to the farthest side of the wall from the release spot. While resistant mosquitoes could stay close to the repellent release spot. When cumulative repellent concentration became high, mosquitoes were pushed away from the repellent release spot. Simulation results are being validated using the experimental data in the MalariaSpheresand laboratory.

ASSESSING THE RELATIVE ABUNDANCE OF MALARIA VECTORS TRAPPED INDOORS AND OUTDOORS IN CHIKHWAWA, SOUTHERN MALAWI

Monicah M. Mburu[1], Kennedy Zembere[2], Themba Mzilahowa[2], Alexandra Hiscox[1], Willem Takken[1], Robert McCann[1]

[1]Wageningen University and Research, Wageningen, Netherlands, [2]College of Medicine, University of Malawi, Blantyre, Malawi

Monitoring the abundance of malaria vectors is important for assessing potential changes in malaria transmission. Most of the current sampling methods for malaria vectors are designed to work indoors, but the importance of sampling outdoors is increasingly being recognized together with the potential for outdoor malaria transmission. The Suna trap is a recently developed odour-baited trap, which can be set either indoors or outdoors. Because the trap is designed to attract host-seeking mosquitoes, two Suna traps simultaneously set indoors and outdoors at the same house may potentially compete with each other, biasing any comparison of indoor and outdoor sampling. Our objective was to assess the potential for this competition between traps. The study was conducted for 24 nights in March-May 2017 using a 12 × 12 Latin Square design in 12 houses in a rural area of southern Malawi. Suna traps baited with an attractant blend and carbon dioxide were set at each house in one of three ways: one trap indoors, one trap outdoors or one trap indoors with an additional trap outdoors. Differences in the number of mosquitoes collected were tested using t-tests. We collected 134 female *Anopheles* mosquitoes, 90% of which were identified molecularly as *Anopheles arabiensis.* The number of mosquitoes collected in indoor traps did not differ between houses where a trap was simultaneously used outdoors or not (P = 0.928). Likewise, the indoor trap did not affect outdoor sampling: catch sizes for outdoor traps did not differ between houses where a trap was simultaneously used indoors or not (P = 0.745). Simultaneous indoor and outdoor use of Suna traps at the same house does not reduce the number of mosquitoes collected in either trap, and therefore indoor and outdoor sampling do not need to be done on separate nights. Researchers and malaria control programmes interested in sampling mosquitoes indoors and outdoors with Suna traps can set traps in both locations on the same night, saving time and effort.

876

FINE SCALE BIOTIC AND ABIOTIC EFFECTS OF WEST NILE VIRUS ILLNESS IN HUMANS

Johnny Uelmen[1], Surendra Karki[1], Patrick Irwin[2], Marilyn O'Hara Ruiz[1]

[1]University of Illinois, Urbana, IL, United States, [2]Northwest Mosquito Abatement Distrcit, Wheeling, IL, United States

Since 1999, West Nile virus (WNV) has moved rapidly across the United States, resulting in thousands of human cases. The number of cases and rate of mosquito infection (MIR) varies across years, with an uneven geographic distribution at regional and local scales. Besides differences in the type and amount of mosquito control, fine-scale differences in WNV risk among geographic locations are related to variable microclimates, vegetation and drainage systems, socio-political factors, property tax base of mosquito abatement districts (MADs), and population-level difference in vector biology. Because of the interactions among these multiple factors that affect the locally variable risk of WNV illness, it has been especially difficult to determine the effect of mosquito control on human risk potential. Cook County, comprising the city of Chicago and surrounding suburbs, is among the areas hardest hit by WNV in the United States. After the 2002-2003 WNV outbreak, the four independently operating MADs in the area revised and improved their preparedness and treatment protocols to better address the specific threats posed by WNV. However, despite these changes and active mosquito control efforts, there are consistent, WNV positive pools of adult mosquitoes annually and greater than 350 confirmed WNV human cases and 12 deaths reported in the past 5 years in Cook County alone. Using multivariate statistical approaches to investigate the biotic and abiotic factors that drive the spatially variable risk of WNV in Cook County, our prior study found that hot and dry weather conditions and higher MIR in earlier weeks and higher percentages of the white population increased the probability of an area of having a WNV human case. The higher proportion of high and medium intensity urban areas and open water sources in an area decreased the probability of observing a WNV human case. We aim to add catch basin density and historical mosquito abundance to our existing model at finer spatial scales to create the most robust human WNV risk model to date.

COMPETITIVE INTERACTIONS IN AEDES MOSQUITOES AT CONSTANT AND FLUCTUATING TEMPERATURES

Nnaemeka F. Ezeakacha

Pennsylvania State University, University Park, PA, United States

Mosquitoes have evolved specific responses to variation in environmental conditions and these responses have implications on the outcome of species interactions such as intraspecific and interspecific competition. Investigations on competitive interactions in container mosquitoes so far have mostly been done at constant temperatures despite the importance of fluctuating daily temperatures as a better indicator of field conditions. This study investigated the effects of constant and fluctuating daily temperatures estimated as diurnal temperature range (DTR), on

inter- and intraspecific larval competition between *Aedes albopictus* (Skuse) and *Aedes aegypti* (L.). Larvae of laboratory established colonies were reared under controlled conditions at three constant (20°C, 27°C and 32 °C) and three fluctuating (20°C DTR 10, 27°C DTR 10, and 32 °C DTR 10) low, medium and high-temperature treatments. Overall, fluctuating temperatures led to lower larval survival, and smaller adults than constant temperatures, for both species. At low and medium temperatures, *Ae. albopictus* larval survival and adult mass were minimally influenced by interspecific competition with *Ae. aegypti*. However, at high temperatures, both interspecific and intraspecific competition decreased larval survival and adult mass for both species. These findings improve our understanding of the relationship between temperature variation and species interactions and provide valuable information for modeling of container mosquito population dynamics and intrinsic growth rate of vector populations.

UPGRADE OF A PHYSICAL GENOME MAP FOR AEDES AEGYPTI

Atashi Sharma[1], Vladimir Timoshevskiy[2], Wu Yang[1], Igor Sharakhov[1], Zhijian (Jake) Tu[1], Maria Sharakhova[1]

[1]Virginia Tech, Blacksburg, VA, United States, [2]University of Kentucky, Lexington, KY, United States

Nearly 4 billion of the world's population is currently at risk to contract mosquito borne diseases, with almost 2500 million people prone to dengue infection. *Aedes aegypti* is the principal vector of Dengue, Chikungunya and Zika viruses. Efforts are ongoing to facilitate a better understanding of the *Aedes aegypti* genome to pave ways for vector control. Among mosquitoes, high-coverage genome maps for the African malaria vector *An. gambiae* and *An. albimanus* were developed, covering 84.5% and 98.2% of the *An. gambiae* and *An. albimanus* genomes, respectively. The recent Hi-C-based scaffolding approach assigned 93.6% of the original L3 *Ae. aegypti* draft genome assembly to three chromosomes thus creating the L4 assembly. However, the genomic coordinates of L4 assembly do not have any correspondence with chromosomal bands. Further, it lacks data from male sex locus as the L4 assembly was based on females only. To develop a fine-scale physical genome map anchoring genomic contigs to their chromosomal positions, we compared the *Ae. aegypti* assembly coordinates of ~500 previously and newly mapped BAC clones from the NDL library with their positions on the chromosomes using multicolor fluorescence *in-situ* hybridization (FISH). We performed repeat masking of the BAC-end sequences and aligned them to the recent L5 assembly which includes the male sex locus (M locus). We were able to match 403 BAC-end sequences with the L5 genome assembly. We identified contradictions of the genome coordinates with chromosomal positions of 10 BAC clones, which represent 2.6% of the mapped BAC clones. Overall, the BAC-clone-based map validated the high quality of the L5 assembly and presents a final resolution of 5-10 MB, the highest density map for *Ae. aegypti* until now. The genome coverage of the map equals 93.4% representing the second highest genome coverage among mosquitoes. We used this map to validate the sex locus in different strains of *Ae. aegypti*. These efforts will help to identify, target and manipulate epidemiologically important traits and to develop potential new strategies for vector control.

ENTOMOLOGICAL INVESTIGATIONS INTO RIFT VALLEY FEVER VIRUS TRANSMISSION POTENTIAL ON FEEDLOTS IN COLORADO

Daniel A. Hartman, Lauren Rice, Justin DeMaria, Erin Borland, Nicholas Bergren, Lucy Robb, Anna Fagre, Rebekah Kading

Colorado State University, Fort Collins, CO, United States

Rift Valley Fever Virus (RVFV) is an emerging arbovirus that infects ruminants and humans. The 20th century saw notable range expansions of the virus to new geographies outside of continental Africa. Many gaps remain in our knowledge of potential transmission cycles of RVFV in the United States. Several species of mosquito native to the U.S. are competent vectors in the laboratory, with especially high vector competence observed of Cx. tarsalis. We conducted field studies to determine the extent to which native mosquitoes could bridge transmission of RVFV from potential wildlife hosts to domestic ungulates at feedlots in Colorado. We used a paired-site design, sampling mosquitoes at feed lots and nearby control sites in Colorado from early May to late August using CDC light traps. We characterized mosquito diversities at each site using Hill numbers, and investigated differences between mosquito community assemblages by habitat type (feedlot vs control) using ordination and model-based analysis of multivariate abundance data. Blood meal analysis was performed on engorged specimens to determine differences in feeding behaviors at feedlots versus control sites. We also compared West Nile Virus (WNV) infection rates in Cx. tarsalis collected at feedlots and nearby control sites to investigate whether dispersal is limited across the feedlot/wildlife interface. Mosquito diversities were generally higher on control sites than on paired feedlot sites. Mosquito community assemblages differed significantly by site type (feedlot vs. control). Cx. tarsalis fed on a high diversity of vertebrates hosts at control sites, but predominantly cattle on feedlots, indicating potential to bridge potential sylvatic transmission to domestic ungulates. Infection rates of Cx. tarsalis with WNV did not differ between paired sites, offering evidence that Cx. tarsalis mosquitoes disperse readily across the feedlot/wildlife interface. Overall, these results show that while feedlots impact the mosquito community measures, Cx. tarsalis may bridge hypothetical sylvatic transmission cycles to domestic ungulates.

880

INCREASED ADULT *AEDES AEGYPTI* AND *CULEX QUINQUEFASCIATUS* (DIPTERA: CULICIDAE) ABUNDANCE IN KAOHSIUNG CITY, TAIWAN

Ting-Wu Chuang

Department of Parasitology and Tropical Diseases, School of Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan

The assumption that vector abundance differences might drive spatial and temporal heterogeneities in vector-borne disease transmission is common, though data supporting it is scarce. Here, we present data from two common mosquito species *Aedes aegypti* (Linnaeus) and *Culex quinquefasciatus* Say, biweekly sampled as adults, from March 2016 through December 2017, with BG-sentinel traps in two neighboring districts of Kaohsiung City (KC), Taiwan. One district has historically been a dengue transmission hotspot (Sanmin) and the other a coldspot (Nanzih). We collected a total 41,027 mosquitoes, and we found that average mosquito abundance (mean ± S.E.) was higher in Sanmin (*Ae. aegypti*: 9.03 ± 1.46 ; *Cx. quinquefasciatus*:142.57 ± 14.38) than Nanzih (*Ae. aegypti*: 6.21 ± 0.47 ; *Cx. quinquefasciatus*: 63.37 ± 8.71) during the study period. In both districts *Ae. aegypti* and *Cx. quinquefasciatus* population dynamics were sensitive to changes in temperature, the most platykurtic environmental variable at KC during the study period, a pattern predicted by Schmalhausen`s law, the principle stating that organisms are more sensitive to small changes in environmental variables whose average value is more uncertain than its extremes. Our results also suggest that differences in *Ae. aegypti* abundance might be responsible for spatial differences in dengue transmission at KC, and our comparative approach, where we also observed a significant increment in the abundance of *Cx. quinquefasciatus* in the dengue transmission hotspot, suggests this area might be more likely to experience outbreaks of other vector borne diseases, and should become a primary focus for vector surveillance and control.

881

XENODIAGNOSIS TO DETECT *L.DONOVANI* INFECTION IN VISCERAL LEISHMANIASIS, POST KALA-AZAR DERMAL LEISHMANIASIS AND ASYMPTOMATIC SUBJECTS

Shyam Sundar

Institute of Medical Sciences, Banaras Hindu University, Varanasi, India

Visceral leishmaniasis (VL) is a chronic protozoan parasitic disease causing substantial mortality and disability. VL Elimination campaign has been running on the Indian Subcontinent since 2005. However, to achieve and sustain elimination of VL, knowledge gaps on infection reservoirs and transmission need to be addressed. In the present study, we investigated the role of *L. donovani* exposed individuals from across the infection spectrum in driving the transmission of endemic VL. Direct xenodiagnosis was performed using 10 male and 30 female *P. argentipes* sand flies on active VL patients (n=74), Endemic healthy aymptomatics (EHC; n=56) and PKDL patients (n=08). After 60 hrs of post blood meal feeding, only blood fed flies were dissected and infections of sand flies were evaluated by microscopy. We found varying sand fly feeding response (3-94%, Mean: 66.7%) with VL patients, 56.2-89.6% (Mean: 65.4) with Post kala-azar (PKDL) patients and (3-94%, Mean: 66.7%) with EHCs. Modeling analysis for the proportion of flies that get infected with VL within each class of severity of disease showed that infectivity of flies correlates with severity of disease. We found 24.02% (ODDs ratio: 69.5) of flies infected in the highly severe disease patients (splenic score=5) compared to 0.45% infection in flies in subjects with splenic score-1. In PKDL, we found infection in flies was higher when exposed on skin lesions; and nodular forms are more infectious compared to macular forms. Importantly, none of the asymptomatic subjects was able to transmit parasite to flies. The study on human shows that VL and PKDL patients harbored parasites in sufficient numbers to promote infections in vector sand flies. <!--EndFragment-->

882

DENSITY AND INDEX OF MOSQUITOES BEFORE AND AFTER HURRICANE MARIA IN SOUTHERN PUERTO RICO

Robert Rodríguez-González, Luisa M. Morales, Mayra E. Roubert, Vivian Green, Juan C. Orengo

Ponce Health Sciences University, Ponce, Puerto Rico

In 2017 and 2018 the distribution of mosquitoes has varied due to environmental and climatic factors, such as Hurricane Maria. Our objectives: 1) Evaluate the environmental and climatic factors related to the density and distribution of mosquitoes during the dry period of 2017 and the dry period of 2018; 2) Determine entomological index for 2018. 3) Determine hotspots and coldspots in the southern region of Puerto Rico. An ecoepidemiology substudy in the southern region of Puerto Rico was performed to evaluate the environmental factors, climatic factors and density of mosquito. It was observed that when the wind speed increases the frequency of mosquitoes decreases ($r = -0.8263$) ($p<0.05$). In extreme temperature and pressures the distribution of mosquitoes was lower, however, precipitations led to an increase in mosquitoes. In the dry period during 2017 it was observed that the mosquito density was 20 mosquitoes, while in the dry period of 2018 the mosquito density was 128 mosquitoes. During the rainy season of 2018 (after Hurricane Maria) the larvae entomological index was 59%, the pupal entomological index was 36% and the oviposition entomological index was 72%. During the dry season of 2018 were 53%, 29% and 65% respectively. In the southern region of Puerto Rico, the hotpots were statistically different compared to the coldspots (z score > 2.58) ($p<0.001$). The hotspots and coldspots maintained a pattern of grouped values ($p<0.05$). Adjusting for collected samples the hotpots were not statistically different compared to the coldspots (z score $= -1.65 - 1.65$) ($p>0.001$). Therefore, understanding the environmental factors, climatic factors, and the entomological index leads to knowing the distribution of mosquitoes and being able to carry out interventions and vector control.

883

LEVERAGING ARBOVIRAL SURVEILLANCE DATA TO INFORM PUBLIC HEALTH RESPONSES IN BARBADOS

Catherine A. Lippi[1], Anna M. Stewart-Ibarra[2], Adrian M. Trotman[3], Roché Mahon[3], Shelly-Ann Cox[3], Leslie Rollock[4], Marquita Gittens-St. Hilaire[5], Stephen Daniel[4], Colin J. Carlson[6], Sadie J. Ryan[1]

[1]Quantitative Disease Ecology and Conservation (QDEC) Lab Group, Department of Geography, University of Florida, Gainesville, FL, United States, [2]Center for Global Health and Translational Science, SUNY Upstate Medical University, Syracuse, NY, United States, [3]Caribbean Institute for Meteorology and Hydrology, Bridgetown, Barbados, [4]Ministry of Health, St. Michael, Barbados, [5]University of the West Indies at Cave Hill, Faculty of Medical Sciences, St. Michael, Barbados, [6]Georgetown University, Washington, DC, United States

The island nation of Barbados (pop. ~285,000), located in the Caribbean, has long contended with public health threats posed by *Aedes*-transmitted diseases, in particular, dengue fever. More recently, both Chikungunya and Zika joined dengue as challenges to public health. Management of arboviral diseases in Barbados is necessary not only for protecting the health of the resident population, but also ensuring the continued success of the island's thriving tourism industry. The establishment of *Aedes* mosquitoes in Barbados and throughout most of the Caribbean has rendered islands vulnerable to emerging pathogens and outbreak events. In 2015, Zika spread rapidly throughout the Americas, and its proliferation through the Caribbean followed suit. Barbados reported its first confirmed autochthonous Zika transmission to the Pan American Health Organization (PAHO) in January 2016, a month before the global public health emergency was declared. Following detection of suspected Zika cases on Barbados in 2015, 926 individuals were described as suspected cases, and 147 lab confirmed cases were reported through December 2016. Our work on dengue incidence in Barbados from 2013-2016, in which georeferenced cases of dengue fever reported to the Ministry of Health (n=1,117) were aggregated to health districts, demonstrated that cases were not randomly distributed in space. Utilizing local Moran's I and spatial scan statistics, we detected areas of significantly high and low disease activity that shifted between years, an indication of spatially and temporally variable disease transmission risk. The ability to detect critical hotspots of transmission activity enables public health agencies to target mosquito control efforts, strengthening the capacity to curtail outbreaks and respond to, and reduce, the threat of emerging mosquito-borne pathogens in the Caribbean. Moving forward, we recommend further incorporation of spatially explicit methods of outbreak detection into existing surveillance frameworks.

884

GEOSPATIAL ANALYSIS OF HIGH-RISK AREAS FOR VECTOR-BORNE TRANSMISSION USING REMOTE SENSING TECHNOLOGIES

Melissa Nolan[1], Sarah Gunter[2], Abi Oluyomi[2], Mustapha Debboun[3], Chris Fredregill[3], Kyndall Dye-Braumuller[3], Tim Nedwed[4], Jerry Helfand[2]

[1]University of South Carolina, Columbia, SC, United States, [2]Baylor College of Medicine, Houston, TX, United States, [3]Harris County Mosquito Control, Houston, TX, United States, [4]ExxonMobil, Spring, TX, United States

Mosquitoes kill more humans than any other creature on earth. As a consequence of a wide range of mosquito breeding habitats globally, the high abundance of competent arboviral vector species in existence, and lacking international mosquito control infrastructure, arboviral diseases cause an estimated 300 million infections and 500,000 deaths annually. While effective insecticides exist, modest vector control department budgets prohibit their broad distribution, warranting cost-effective measures for enhanced and targeted insecticide applications. Our current project was a collaborative effort to develop a predictive

model of mosquito breeding habitats utilizing advanced remote sensing technologies. To ensure maximum public health benefit, we also evaluated the association of the model's detected mosquito breeding habitats to real-world mosquito abundance and mosquito pool arboviral disease status within our selected study areas. Our current project in Harris County, Texas focuses on *Culex sp*. and *Aedes spp*. mosquitoes in the downtown-ship channel corridor and the suburban communities of Spring and Katy. We employed a variety of remoting sensing techniques including object-oriented image classification, vegetation and water indices, and spectral readings for enhanced classification. This unique project brought together a diverse group of experts in an innovative way to tackle one of the most important public health concerns of our time.

885

IDENTIFICATION OF *PLASMODIUM FALCIPARUM*-INFECTIOUS *ANOPHELES COLUZZII* MOSQUITOES USING NEAR-INFRARED SPECTROSCOPY

Dari F. Da[1], Pedro M. Esperanç[2], Bernard M. Somé[1], Maggy T. Sikulu-Lord[3], R. Serge Yerbanga[1], Thierry Lefèvre[4], Karine Mouline[4], Karidia Wermé[1], Floyd Dowell[5], Roch K. Dabiré[1], Thomas S. Churcher[2]

[1]Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso, [2]MRC Centre for Outbreak Analysis and Modelling, Infectious Disease Epidemiology, Imperial College London, London, United Kingdom, [3]Queensland Alliance of Agriculture and Food Innovation, The University of Queensland, Brisbane, Queensland, Australia, [4]MIVEGEC, IRD, CNRS, Montpellier Univ., Montpellier, France; Institut de Recherche en Sciences de la Santé,, Bobo-Dioulasso, Burkina Faso, [5]Stored Product Insect and Engineering Research Unit, United States Department of Agriculture/ Agricultural Research Services, Center for Grain and Animal Health Research, Manhattan, KS, United States

The prevalence of infectious mosquitoes is used to assess the effectiveness of vector control against malaria. Mosquitoes with salivary gland sporozoites can be identified by microscopy following manual dissection, ELISA technique or using expensive molecular methods. These low throughput techniques are impeding routine entomological surveillance especially in areas with high mosquito densities. This study evaluates the potential of near-infrared spectroscopy (NIRS) technique to differentiate between *Plasmodium* infected and uninfected mosquitoes. Colony of *Anopheles coluzzii* mosquitoes were fed on blood collected from gametocyte positive volunteers naturally infected with *Plasmodium falciparum* using direct membrane feeding assay in Burkina Faso. Two hundred and ten mosquitoes (111 in exposed group and 99 in control group) were killed 14-18 days-post blood-feeding and scanned using NIRS. Infection status was confirmed in individual mosquitoes using qPCR as the reference method. The overall predictive accuracy for differentiating infectious from uninfectious mosquitoes was 72%, and the false negative and false positive rates were 37% and 20% respectively. The area under the receiver operating characteristic curve was 0.80. The moderate diagnostic accuracy observed here might be improved by modifying the machine learning methods used to convert spectral data into estimates of infectious status or by improvements in the lights source, fibre optics, or NIR sensors. NIRS is a rapid and non-destructive scanning technique that has the potential to be used to measure sporozoite prevalence though further work is needed to increase its precision and validate the technique in wild caught mosquitoes.

Sampling outdoor biting malaria vectors is vital to understanding peri-domestic transmission risk and evaluating outdoor control interventions and is particularly important in pre-elimination settings or where residual vectors may maintain transmission. However, current methods for measuring outdoor biting suffer from serious ethical and technical limitations. To address this, we developed a host decoy trap (HDT), which exploits known behaviors of *Anopheles* mosquitoes. By incorporating olfactory, visual and thermal stimuli, the HDT mimics a human host and attracts *Anopheles*, inducing them to land and become trapped. We tested the HDT against human landing catches (HLC) and CDC light traps indoors and outdoors in four different ecological and epidemiological settings in west Africa: 1) an area of intensive rice irrigation and 2) traditional Sudanian savanna subsistence farming in Burkina Faso; 3) an area of urban coastal malaria transmission in Benin; and 4) a low vector density setting with seasonal transmission in highland Cameroon. Latin square replicates were completed across a range of climatic periods and vector densities. We conducted a simultaneous participatory technology assessment to determine the user acceptability of each method, focusing on ease of use, perceptions of risk and confidence. In total, 19,289 *Anopheles* were collected. Outdoors, HDTs matched or outperformed HLC on vector abundance across all settings, except for one village in Burkina Faso where the HLC caught more *Anopheles*. HDT catch was significantly higher than HLC in higher density periods. The CDC light trap caught fewest *Anopheles*. Indoors, the HLC caught consistently more *Anopheles* than the other methods. Field collectors cited high confidence in the HDT relative to the other methods, finding it easy to use, although more effort was required to set up the trap. They generally disliked HLCs as their sleep was disturbed, impacting on the following day's activity, and they perceived risks associated with exposure to vector-borne diseases and the night air. The HDT has potential as an acceptable standardized outdoor sampling method for malaria vectors.

PLASTICITY OF HOST SELECTION, NON-RANDOM HUMAN FEEDING AND SPATIAL HETEROGENEITY OF EXPOSURE TO MALARIA VECTORS IN PAPUA NEW GUINEA

John B. Keven[1], Michelle Katusele[2], Rebecca Vinit[2], Daniela R. Rodriguez[3], Manuel W. Hetzel[3], Moses Laman[2], Leanne J. Robinson[4], Stephan Karl[2], Edward D. Walker[1]

[1]Michigan State University, East Lansing, MI, United States, [2]Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, [3]Swiss Tropical and Public Health Institute, Basel, Switzerland, [4]Burnet Institute, Melbourne, Australia

In Papua New Guinea (PNG), malaria transmission persists despite decade-long implementation of long-lasting insecticidal nets (LLINs) nationwide. The resilience to LLINs is attributed to ecological and behavioral factors rather than insecticide resistance. We investigated host selection and spatial distribution of human-vector contact of four *Anopheles* species in four villages of PNG, two with high (>70 %) and two with low (<55 %)

LLIN use. Anophelines were sampled using barrier screen and landing catch methods. Mosquito and blood meal host species were identified by PCR methods. Human blood meals were individualized using microsatellite DNA profiling. The ratio of human to nonhuman blood meals for *Anopheles punctulatus*, *Anopheles farauti* and *Anopheles longirostris* conformed to the census ratio in villages with low LLIN usage but was lower in villages with high LLIN usage. In contrast, the ratio of human blood meals for *Anopheles koliensis* was high in all villages regardless of LLIN usage. These results show that *Anopheles farauti*, *Anopheles punctulatus* and *Anopheles longirostris* are opportunistic in their host selection and utilize non-human hosts when access to humans is reduced, whereas *Anopheles koliensis* is highly anthropophilic. Of 79 individual people identified in 214 human-fed *Anopheles farauti* blood meals from one of the villages, only a few people (13%) contributed to most (64%) blood meals, indicating non-random human host selection. *Anopheles* landings per person-night (an estimate of bites per person-night) and *Anopheles* density per barrier screen-night were both spatially heterogeneous and overdispersed for all species, indicating aggregation of vectors in certain microenvironments of the villages. The number of landings on humans was greater outdoors than indoors. The spatial heterogeneity of mosquito abundance and exposure may result in spatial heterogeneity in risk of infection within a village. Alternative vector control methods such as treatment of domestic animals with endectocides can be implemented alongside the LLINs to target the outdoor-biting opportunistic vectors.

EFFECT OF LARVAL DIET, AGING, AND ZIKV INFECTION ON IMMUNE GENE REGULATION IN AEDES AEGYPTI

Jillian Masters[1], Austin Drury[1], Catherine Dean[2], Donald A. Yee[2], Jonas G. King[1]

[1]Mississippi State University, Mississippi State, MS, United States, [2]University of Southern Mississippi, Hattiesburg, MS, United States

Arboviruses transmitted by mosquitoes are a significant cause of mortality throughout the world. Transmission of these disease-causing agents is dependent upon the existence of competent arthropod vectors that have the capability to maintain the pathogen, then transmit it to a subsequent host. Multiple studies of vector competence have suggested that the interaction between pathogens and the mosquito immune system plays a role in determining competence of the mosquito as a disease vector. In this study, we analyzed relative expression of a suite of immune genes from ZIKV infected *Aedes aegypti*. Mosquitoes were reared as part of a larger study investigating the effects of larval diet on vector competence. Standard extraction techniques and cDNA synthesis, followed by qRT-PCR, using previously published primer sets, was used to analyze relative expression at the transcriptomic level. Significant differential expression was observed between mosquitoes from different larval diets and between ZIKV-infected and control mosquitoes in all immune genes analyzed, the general trend being down-regulation of genes following viral infection and under nitrogen-poor rearing conditions. These results represent a step towards illuminating the influence of diet and viral infection on the immune response in mosquitoes, which may have subsequent consequences for the transmission of arboviruses. Results will also be presented from ongoing RNAseq analyses of the effect of larval diet on global transcript expression and a study using the same suite of *Aedes* immune genes to measure gene expression as mosquitoes age under laboratory conditions.

SIMULATING THE EFFECTS OF CLUMPED EGG LAYING ON MOSQUITO POPULATION DYNAMICS IN RELATION TO GENE-DRIVE INTERVENTIONS

Aaron L. Morris, Neil Ferguson, Azra Ghani

Imperial College London, London, United Kingdom

Gene-drive based vector control methods are a rapidly developing tool in the fight against malaria. They utilise highly targeted insertions of genes to express specific traits, such as biases in offspring sex ratio or inhibited vector competence, which are preferentially inherited by copying themselves between chromosomes. Although theoretically self-sustaining, most gene-drive methods are sensitive to numerous aspects of local mosquito population dynamics. Often however, due to gaps in our knowledge, mathematical modelling of gene drive systems makes highly simplifying assumptions about key aspects of mosquito ecology. There is an urgent need to better understand fine scale population processes to improve predictions of the likely impact of gene-drive releases and refine development of target product profiles. The principal drivers of local mosquitoes dynamics can be traced to the larval stages, where density-dependent mortality in larval habitats is a key regulator of local adult density. In this study, we explored these drivers by simulating non-homogenous egg-laying over time and analysing its relationship with differing functional forms of density dependence. We developed a discrete-time stochastic model of mosquito population dynamics, which incorporated the random, temporal clumping of egg laying. The model was fitted to historical longitudinal mosquito trapping data using advanced particle MCMC methods. From this we were able to better quantify the relationship between clumping of egg laying and density-dependent regulation of larval populations, and thus refine estimates of the mosquito reproduction number, Rm - a key determinant of the predicted impact of gene-drive interventions. We find incorporation of

clumping of egg-laying improves model fit, and reduces estimates of Rm, thus making establishment and spread of gene-drive constructs more likely than predicted by models assuming higher Rm values.

890

PARITY, PRESENCE, AND PREVALENCE: USING MOSQUITO DATA AND GONOTROPHIC CYCLE DYNAMICS TO MONITOR DISEASE IN ELIMINATION-TARGETED SETTINGS

Emma L. Davis[1], Corrado Minetti[2], Lisa J. Reimer[2], Matt J. Keeling[1], Deirdre Hollingsworth[3]

[1]University of Warwick, Coventry, United Kingdom, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]Big Data Institute, University of Oxford, Oxford, United Kingdom

Mosquito-borne diseases represent a substantial portion of the total global disease burden. In the case of malaria, onchocerciasis, and lymphatic filariasis there are global elimination campaigns underway. Sustaining public and political support near the end of elimination campaigns can be difficult due to the difficulties posed by accurate prevalence and incidence estimation due to low case numbers. Xenomonitoring, the use of vector data to detect pathogen presence in human populations, has been cited as a potential tool for improving surveillance at low prevalences. However, there is an expectation that effective xenomonitoring requires financially infeasible sample sizes and yields intractable data. Despite these issues, the potential benefits of xenomonitoring are obvious; data collection would be non-invasive and allow greater access to hard-to-reach populations, giving a clearer snapshot of transmission. Using a novel feeding cycle model we estimate the probability of a parous vector being infectious given different human prevalence levels of a particular disease, to provide a simple tool for relating infection in mosquitoes to that in humans. The more cycles a vector has completed, the higher the probability it will be infectious, leading to a relationship between parity and prevalence that will vary depending on mosquito species and both infection and mosquito longevity. We calculate explicit expressions for the entomological inoculation rate, the basic reproductive number, and vectorial capacity. These important measures of vector-borne pathogen transmission are widely used but can be hard to estimate, our results describe a method of direct calculation from mosquito data and allow investigation of the potential impact of vector control measures. We use these tools to present techniques for calculating sufficient sample sizes when confirming presence or absence of disease, as well as demonstrating the relationship between human and vector prevalence across a range of diseases.

891

TOWARDS TARGETED IRS: MAPPING AND TRACKING THE INDOOR RESTING BEHAVIORS AND PREFERENCES OF AEDES AEGYPTI IN SEMI-FIELD EXPERIMENTS

Luca Facchinelli[1], Rosângela M. Barbosa[2], Eloina M. Santos[2], Vitaly Voloshin[3], Shihong Jiang[3], Catherine E. Towers[3], David Towers[3], Philip J. McCall[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]Instituto Aggeu Magalhães, Fiocruz Pernambuco, Recife, Brazil, [3]University of Warwick, Coventry, United Kingdom

The peridomestic behavior of *Aedes aegypti*, the primary mosquito vector of arboviruses to humans, is often speculated or unknown despite the considerable body of literature available. Its endophilic propensity is an attractive target for control by indoor residual spraying (IRS). However, IRS needs large insecticide quantities, is potentially harmful to householders and is often poorly accepted. A deeper understanding of *Ae. aegypti* indoor resting habits could identify key indoor sites that are often/always used for resting, greatly reducing the area requiring IRS. In the literature *Ae. aegypti* is often reported to rest on surfaces below 1.5 m height, but reports provide minimal information on resting activity over time. We investigated the basic resting behavior of *Ae. aegypti* in Recife, Brazil using an unfurnished room, with white walls and ceiling coated in a non-setting adhesive (the Sticky Room). In a first experiment, the entire room was coated, and adult mosquitoes (both sexes) and different physiological stages were released. Forty minutes later, the mean percentages and standard deviations (SD) collected within 1 m from the floor were 76.1 (7.2), 66.9 (7.2), and 60.6 (6.9) for males, unfed and bloodfed females respectively. In the second experiment, only two 20 cm strips of adhesive were applied to the walls, as horizontal bands covering 0-20 cm and 160-180 cm from the floor. Twenty-four hours later, the percentages and SD of males, unfed and fed females captured on the 20-cm sticky strip closest to the floor were 85 (11), 90 (4), and 79 (17), respectively. These preliminary results indicate that in the absence of visual or other stimuli, the majority of *Ae. aegypti* adults have a strong tendency to visit a restricted area of the walls adjacent to the floor. The current series of experiments employs a video system to track mosquito movement and resting preferences in a more complex environment, incorporating modular 3D shapes (simulated furniture) and cryptic resting sites. We present these experimental results as evidence for the potential of householder-delivered targeted IRS as an effective means of *Aedes* control in urban communities.

PHYLOGENETIC ANALYSES OF ALL FOUR DENGUE VIRUS SEROTYPES DETECTED IN WESTERN KENYA, 2014-2015

Jimmy Hortion[1], Sean V. Edgerton[2], **David M. Vu**[3], Noah Mutai[4], Bryson A. Ndenga[4], Shannon N. Bennett[2], A. Desiree LaBeaud[3]

[1]Ecole Normale Supérieure de Lyon, Lyon, France, [2]California Academy of Sciences, San Francisco, CA, United States, [3]Stanford University School of Medicine, Stanford, CA, United States, [4]Kenya Medical Research Institute, Kisumu, Kenya

Reports of dengue virus (DENV) cases and outbreaks provide evidence of ongoing DENV transmission in Kenya. Yet, little is known about the circulating virus strains, limiting our understanding of viral transmission dynamics. To address this gap in knowledge, we used next-generation sequencing to characterize the phylogeny of all four DENV serotypes (DENV-1 to -4) identified in acutely febrile children, living in western Kenya between 2014-2015. The subjects were participants in our study of pediatric arboviral disease burden, who presented with fever to either of two regional health centers that served the communities of Chulaimbo and Kisumu. RNA was extracted from blood samples and reverse transcribed to cDNA in Kenya. cDNA was then shipped to the US for further analysis. We used the MiSeq platform (Illumina, San Diego, CA), to sequence cDNA from children who were positive for DENV by conventional PCR. To date, seven genomes have been fully sequenced: four DENV-1, and one each of DENV-2, -3, and -4. Phylogenetic analysis reveals four different genotypes as well among the four serotypes, with possibility of exhibiting distinct levels of genetic variation. Further whole-genome molecular evolutionary analysis may reveal varying trends in selection pressures and phylodynamics among the four co-circulating DENV serotypes. These data provide valuable insight into the evolution of DENV in Kenya and provide an important reference for future investigation of arboviral transmission dynamics.

EVALUATION OF NEXT GENERATION SEQUENCING AND BIOINFORMATICS PIPELINE FOR PATHOGEN IDENTIFICATION USED AT THE DEPARTMENT OF VIROLOGY, ARMED FORCES RESEARCH INSTITUTE OF MEDICAL SCIENCES (AFRIMS), BANGKOK, THAILAND

Piyawan Chinnawirotpisan[1], Wudtichai Manasatienkij[1], Khajohn Joonlasak[1], Chonticha Klunhthong[1], Angkana Huang[1], Irina Maljkovic Berry[2], Wiriya Rutvisuttinunt[2], Lindsay Morton[3], Kimberly A. Bishop-Lilly[4], Michael Wiley[5], Gustavo Palacios[5], Theron Hamilton[4], Brett Forshey[3], Richard G. Jarman[2], Louis R. Macareo[1], Alden L. Weg[1], Damon W. Ellison[1]

[1]Department of Virology, United States Army Medical Directorate, Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [2]Viral Disease Branch, Walter Reed Army Institute of Research, Silver Spring, MD, United States, [3]Global Emerging Infections Surveillance Section, Armed Forces Health Surveillance Branch, Silver Spring, MD, United States, [4]Genomics and Bioinformatics Department, Biological Defense Research Directorate, Naval Medical Research Center, Frederick, MD, United States, [5]Center of Genome Sciences, United States Army Medical Research Institute of Infectious Diseases, Fort Detrick, MD, United States

Next Generation Sequencing (NGS) technologies and bioinformatics tools provide broad detection of various pathogens in clinical specimens and are widely used in public health laboratories. Different protocols/pipelines have been developed for pathogen identification and discovery. To obtain optimal pipelines, evaluation and standardization is necessary. The Department of Virology, AFRIMS, participated the Next Generation Sequencing and Bioinformatics Consortium Pathogen Discovery Pilot supported by Global Emerging Infections Surveillance (GEIS) and conducted by Walter Rees Army Institute of Research (WRAIR) in collaboration with NMRC-BDRD and USAMRIID-CGS. A panel of 20 unknown extracted nucleic acid samples was created, validated, and shipped to AFRIMS with clinical case descriptions. To identify pathogens in the panel, four NGS runs were performed using the Illumina MiSeq with ten samples per run. Sample preparation procedures included 1) RNA sequencing using TruSeq Stranded Total RNA with Ribo-Zero Globin kit, 2) DNA sequencing using QIAseq FX DNA sample preparation kit. The data were processed and analyzed using four bioinformatics pipelines included EDGE, CLARK, Kraken and Trinity2. Adenovirus, influenza, Zika, dengue, chikungunya, and Japanese encephalitis viruses, *Acinetobacter baumannii*, and *Klebsiella Pneumoniae* were identified. All detected pathogens were confirmed by reference mapping and conventional laboratory assays included PCR, RT-PCR, and 16s sequencing. Phylogenetic analysis was performed with some pathogens. Results were sent to WRAIR for evaluation. AFRIMS was able to identify 95% of the pathogens in the panel (95% CI: 75-100), 87.5% sensitivity (95% CI: 47-99), 100% specificity (95% CI: 74-100), 12.5% false negative rate (95% CI: 1-53), and 0 false positive rate (95% CI: 0-24). Our data demonstrated that RNA sequencing and bioinformatics pipelines were optimal for identification of both DNA and RNA pathogens. The pilot helped to monitor the quality and accuracy of our NGS/bioinformatics pipeline and provided useful suggestions for improvement.

894

HOUSEHOLD-BASED CLUSTER INVESTIGATIONS DURING AN OUTBREAK OF DENV-2 IN AMERICAN SAMOA

Caitlin Cotter[1], Aifili J. Tufa[2], Kyle Ryff[1], Stephanie S. Johnson[3], Mary Matai'a[4], Jorge Munoz-Jordan[1], Gabriela Paz-Bailey[1], Scott Anesi[4], Matthew J. Lozier[1], Tyler M. Sharp[1]

[1]Centers for Disease Control and Prevention/NCEZID/Dengue Branch, San Juan, PR, United States, [2]PIHOA, Honolulu, HI, United States, [3]CSTE, Atlanta, GA, United States, [4]American Samoa Department of Health, Pago Pago, American Samoa, United States Minor Outlying Islands

The U.S. territory of American Samoa (AS) experienced outbreaks of chikungunya virus (CHIKV) in 2014, dengue virus type-3 (DENV-3) in 2015, and Zika virus (ZIKV) in 2016. The AS Department of Health reported 594 laboratory-positive cases (10.8 per 1,000 pop.) from a dengue virus type-2 (DENV-2) outbreak during November 1, 2016–January 12, 2018. As this outbreak followed an outbreak of ZIKV, it provided an opportunity to evaluate DENV infection after ZIKV exposure. Household cluster investigations were conducted during September–October 2017 to identify individual and behavioral risk factors for DENV infection. We hypothesized that antibodies from previous infection with heterologous flaviviruses may confer protection against symptomatic dengue disease, as opposed to the antibody-dependent infection enhancement seen in some cases of heterotypic sequential DENV infection. PCR- or NS1-positive dengue patients were visited within 30 days of illness onset, and households within 50 meters of index case-patients' households were invited to participate. Questionnaires were administered to collect data on individual- and household-level characteristics, behaviors, and recent symptoms of acute febrile illness. Serum specimens were collected and tested by RT-PCR and ELISA for nucleic acid and IgM/IgG antibodies against DENVs, ZIKV, and CHIKV. Among 228 participants, 9 (3.9%) were dengue positive (DENV+), 2 by RT-PCR and 7 by IgM. Seven DENV+ participants (77.8%) were febrile, as compared to 23.3% of DENV-negative participants (Chi2 p-value 0.0002). In unadjusted logistic regressions, age <18 years, income over $25,000/year, recent febrile illness, and having a septic tank (Chi^2 p-values = 0.013, 0.010, 0.004, and 0.042, respectively) were associated with DENV infection. Next steps include measurement of anti-ZIKV IgG antibodies by microimmunoassay and analyses of associations between DENV disease and previous ZIKV infection. As recurrent DENV outbreaks have affected AS, patients may be susceptible to severe dengue. Mosquito avoidance behaviors should be stressed, and those with acute febrile illness should seek medical care.

895

EFFECT OF THE SALIVA OF DENGUE TRANSMITTER MOSQUITO *AEDES AEGYPTI* ON DENGUE VIRUS INFECTION OF PRIMARY CULTURES OF FIBROBLASTS

Paola Carolina Valenzuela Leon[1], Julio Garcia Cordero[2], Juan Carlos Barragán Gálvez[2], Jose Luis Maravillas Montero[3], Humberto Lanz Mendoza[4], Jesus Valenzuela[5], Leticia Cedillo Barrón[2]

[1]Vector Biology Section, Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, Rockville, MD, United States, [2]Department of Molecular Biomedicine, Center for Research and Advanced Studies of the National Polytechnic Institute, Mexico City, Mexico, [3]Research Support Network,National University of Mexico (UNAM) and National Institute of Medical Sciences and Nutrition, Mexico City, Mexico, [4]Center for Research on Infectious Diseases (CISEI), National Institute of Public Health (INSP), Cuernavaca, Mexico, [5]Vector Molecular Biology Section , Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, Rockville, MD, United States

Dengue virus (DENV) is transmitted to humans by female *Aedes aegypti* and *Aedes albopictus* mosquitoes, which inoculate virus into the dermis and epidermis while feeding. Previous studies have demonstrated that skin cells are permissive to dengue virus including hematopoietic cells and non-hematopoietic cells, such as fibroblasts, keratinocytes and epithelial cells. These findings suggest that dengue viral replication begins in the skin cells, and these cells will have an important role in the disease process. Fibroblasts are abundant cells in the skin capable of responding to infection in very early stages of infection. Although little information has been generated regarding the additional effects of the saliva of the vector on the infection with Dengue virus. The objective of this work was focused on evaluating the effect of the different components of saliva and DENV-2 on primary skin fibroblasts. Further, we observed a higher viral titer in the supernatants of fibroblasts from different donors, which were infected and

treated with the salivary gland extracts. These data corroborate the fact that some of the components of the saliva might contribute to increasing the viral infection . Furthermore, we evaluated different protein fractions obtained through HPLC, to elucidate the proteins that may be involved in the enhancement of the viral load. Our results strongly suggest that the protein responsible for this effect was a 34 kDa protein. We observed an increase in the infection of fibroblasts in the presence of this protein. This data is consistent with the observed in human keratinocytes, where it has been reported that this protein is capable of increasing the infection of dengue virus in these cells. Since we observed that the 34 kDa protein was partially responsible for this effect and that pre-incubation of the whole extracts was able to further increase in the viral load, we sought to evaluate if the 34 kDa protein is capable of interacting with the Envelope (E) protein of dengue virus through an ELISA and immunofluorescence assays.

896

WHOLE GENOME ANALYSIS REVEALS HIGHLY LOCALIZED TRANSMISSION CHAINS AND A GRAVITY DYNAMIC OF DENGUE 3 SPREAD WITHIN A HYPERENDEMIC CITY IN THE PERUVIAN AMAZON

Simon Pollett[1], Cristopher Cruz[2], Armando Torre[2], Christopher Mores[2], Richard G. Jarman[1], Scott W. Thomas[3], Amy C. Morrison[3], Mariana Leguia[4]

[1]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]US Naval Medical Research Unit - 6, Callao, Peru, [3]University of California Davis, Davis, CA, United States, [4]Pontificia Universidad Catolica del Peru, Lima, Peru

Dispersal hotspots are thought to play a critical role in transmission control during dengue virus (DENV) epidemics. However, data addressing fine-scale spatial dynamics of virus spread are rarely available. From 2002 to 2008 there was a DENV-3 outbreak in Iquitos, a hyper-endemic city and transport hub in the Peruvian Amazon. This provided a unique opportunity to examine the fine-scale spatial dynamics of DENV-3 dispersal using phylodynamic analysis of a large collection of DENV-3 whole genomes. To do so we sequenced 240 DENV-3 positive human sera collected in Peru between 2002 and 2015. The resulting genomes were combined with publicly-available DENV-3 sequences into a dataset of 1055 genomes (174 from Iquitos, 66 from other regions of Peru, 231 from nearby countries and 584 from non-South American countries). Routes of DENV-3 dispersal into Iquitos, and subsequent dispersal through the city's four subdistricts (Belen, Iquitos, San Juan and Punchana), were estimated using time-scaled trees with ancestral geo-state construction. Our results show the 2002-2008 Iquitos epidemic was seeded via Ecuador (prob = 0.99), with an estimated introduction time of about 6 months prior to the first reports of herald cases (TMRCA Jan 2001, 95% HPD Dec 2000 - July 2001). The central subdistrict of Iquitos, which is the most populous, occupied the most ancestral tree space, suggesting it was the origin of epidemic strains sampled in the peripheral, less populated districts of Belen, San Juan and Punchana. Following introduction into the periphery, localized transmission was estimated to last a maximum of 2.54 yrs, with a median strain persistence time of 0.53, 0.57 and 0.60 yrs, respectively. We conclude that DENV-3 epidemic dynamics in Iquitos are characterized by highly localized transmission chains, fine-scale persistence and a gravity dynamic of virus spread, supporting a hypothesis of substantial peri-domestic transmission that has major relevance for transmission control.

897

PREVALENCE OF CHIKUNGUNYA AND DENGUE VIRUS EXPOSURE AMONG CHILDREN IN WESTERN KENYA

Sandra K. Musaki[1], Elysse Grossi-Soyster[2], Bryson Ndenga[1], Francis Mutuku[3], Desiree A. LaBeaud[2]

[1]Kenya Medical Research Institute-Centre for Global Health Research, Kisumu, Kenya, [2]Department of Pediatrics, Division of Infectious Diseases, Stanford University School of Medicine, Stanford, CA, United States, [3]Technical University of Mombasa, Mombasa, Kenya

Chikungunya virus (CHIKV) and dengue virus (DENV) are among the several neglected arboviral diseases that have caused increased epidemics in the recent past globally. In Kenya, however, their occurrence is often underreported due to the low awareness by public healthcare providers and systematic surveillance and also the limited resources available. The objective of this study was to measure the seroprevalence of CHIKV and DENV among asymptomatic children in western Kenya and establish the population at risk of exposure. In 2015, a longitudinal prospective cohort study of 1378 non-clinical subjects aged 2≤17 years was initiated in western Kenya (Chulaimbo and Kisumu villages). Blood samples were obtained and sera tested for CHIKV and DENV exposure using standardized CHIKV IgG and DENV IgG ELISA protocols. During the one year of surveillance, the total prevalence of asymptomatic CHIKV and DENV exposure in the cohort was approximately 6.89% (95/1378) and 0.73% (10/1378) respectively. The total asymptomatic prevalence in the ≤5 year old age group was 0.51% (7/1378) and 0.15% (2/1378); 6-10 years was 2.83% (39/1378) and 0.07% (1/1378); 11-17 years was 3.55% (49/1378) and 0.51% (7/1378) respectively. Our results demonstrate that exposure to CHIKV is more common across all age groups as compared to DENV in western Kenya, with a greater proportion of those exposed ranging between the ages of 6-17 years. This could be due to the fact that this sub-population belongs to the school-going age bracket thus increased duration of exposure to the biting by the vector hence high transmission. The ≤ 5 years of age were less likely to be exposed owing to the fact that most of them had not attained the school going age thus spend their time indoor. Our findings have important implications for assessment of CHIKV and DENV transmission, infection and disease.

898

INFLUENCE OF TEMPERATURE AND RAINFALL ON THE EPIDEMIOLOGY OF ARBOVIRAL DISEASES IN ENVIRONMENTALLY DISTINCTIVE REGIONS OF BRAZIL

Warren Tennant[1], José Lourenço[2], Nuno R. Faria[2], Luiz Carlos Junior Alcantara[3], Mario Recker[1]

[1]University of Exeter, Penryn, United Kingdom, [2]University of Oxford, Oxford, United Kingdom, [3]Fundação Oswaldo Cruz, Salvador, Brazil

Arboviral diseases, such as dengue, chikungunya, and zika, continue to present a substantial and increasing threat to global public health. The timing and severity of epidemic outbreaks are strongly associated with vector suitability, driven primarily by seasonal oscillations in temperature and rainfall. Local variations in climate thus naturally induce significant heterogeneities in arboviral incidence across space and time. However, the relative roles of temperature and rainfall in the emergence and spread of arboviruses in environmentally distinctive settings has only been partially explored. To this end, we constructed a climate-dependent individual-based model to compare the effects of precipitation and temperature on the timing and magnitude of several epidemic outbreaks of dengue, chikungunya and zika, across climatically different regions of Brazil from 2014 to 2017. Our results confirm the important influence of temperature and rainfall on the temporal variation in vectorial capacity, which crucially shapes arboviral disease epidemiology in these regions. Importantly, we also find that the relative effects of different climate variables is strongly dependent on the specific environmental setting, with temperature or rainfall being the main driver for seasonal epidemics in one region but not in another. This further implies that estimation of the latency period between peak annual rainfall, for example, and the timing of an arboviral disease outbreak must be determined at a local scale. Our findings thus contribute to a better understanding of the influence of climate on arboviral disease dynamics and highlight the importance of considering local climatic dependencies when generalizing disease suitability or intervention strategies to wider spatial contexts.

899

DENGUE VIRUS IS AN EMERGING CAUSATIVE AGENT OF ACUTE ENCEPHALITIS SYNDROME (AES) IN INDIA: RESULTS FROM A FOUR-YEAR ENHANCED AES SURVEILLANCE STUDY IN INDIA

Ravi Vasanthapuram[1], Shafeeq Keeran Hameed[1], Anita Desai[1], Reeta Subramanian Mani[1], Vijayalakshmi Reddy[1], Anoop Velayudhan[2], Ravi Yadav[1], Amita Jain[3], Lahari Saikia[4], Achinta Kumar Borthakur[4], Daiji Gogoi[5], Krishna Srinivasan[6], Tapan Dhole[7], Bhaswati Bandopadhyay[8], Nemai Bhattacharya[8], Leena Inamdar[2], Shah Hossain[2], Sharon Daves[2], A. C. Dhariwal[9], P. K. Sen[10], Jagdish Prasad[11], Kayla Laserson[2], Padmini Srikantaiah[2]

[1]National Institute of Mental Health And Neuro Sciences, Bangalore, India, [2]Centres for Disease Control India, New Delhi, India, [3]King George Medical University, Lucknow, India, [4]Assam Medical College, Dibrugarh, India, [5]Guwahati Medical College, Guwahati, India, [6]Vijayanagar Institute of Medical Sciences, Bellari, India, [7]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India, [8]Kolkota School of Tropical Medicine, Kolkota, India, [9]National Centre for Disease Control, New Delhi, India, [10]National Vector Borne Diseases Control Program, New Delhi, India, [11]Director General of Health Services, New Delhi, India

In India, acute encephalitis syndrome (AES) outbreaks are reported annually. While Japanese encephalitis virus (JEV) accounts for 5-35% of reported cases, the etiology of most AES cases in India remains unknown as testing for other pathogens is not routinely performed. As part of the Global Health Security Agenda in India, we established a tiered network of 20 district laboratories and five referral laboratories in three high AES burden states and implemented a testing algorithm to evaluate etiology of AES. All patients fulfilled the WHO AES case definition - "*Acute onset of fever in a person of any age, with change in mental status and/or new onset of seizures (excluding simple febrile seizures)*". Serum and/or cerebrospinal fluid (CSF) samples were collected from AES in-patients from January 2014- December 2017. All samples were evaluated for JEV IgM antibodies. JEV IgM-negative sera were tested for IgM to scrub typhus, dengue virus, and West Nile virus; JEV IgM-negative CSF was tested by PCR for *S.pneumoniae, N.meningitidis, H.influenzae*, herpes simplex virus type 1(HSV), and enteroviruses. Of 10,207 AES patients, 58% were male and the majority (63%) were <15 years. CSF and sera were obtained from 58% of patients; the rest had either CSF (17%) or serum (24%). Overall, an etiological agent was identified in 46.3% patients. JEV IgM was detected in CSF/serum of 16.2% (1658/10,207), while in JE-negative cases, where sera was available, scrub typhus accounted for 16.6% of cases(1165/7011), followed by dengue (5.7%; 340/5992). Dengue was detected in all three states of Assam, Uttar Pradesh and West Bengal. In 6/708 patients where sufficient sample was available, we were able amplify dengue virus RNA in CSF. Through a tiered network of labs and an algorithmic approach, etiologies other than JE were identified in 30% of AES patients; identification would have been limited only to JE (16%) detection in prior routine surveillance. Furthermore, JEV, scrub typhus, and dengue accounted for 94% of all cases where an etiological agent could be identified. These results clearly suggest that dengue virus is emerging as an important etiological agent of AES in India.

DYNAMICS OF T CELL RESPONSES PRIOR TO AND AFTER SECONDARY DENGUE VIRUS INFECTION

Luis A. Sanchez Vargas[1], Anuja Mathew[1], Katie B. Anderson[2], Damon W. Ellison[3], Timothy P. Endy[4], Alan L. Rothman[1]

[1]Institute for Immunology and Informatics, University of Rhode Island, Providence, RI, United States, [2]University of Minnesota Medical School, Minneapolis, MN, United States, [3]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [4]State University of New York-Upstate Medical University, Syracuse, NY, United States

Cytokines secreted by T cells contribute to both protective immunity against dengue virus (DENV) and the pathogenesis of dengue disease. The aim of this study was to define the dynamics and the magnitude of T cell responses over time after DENV infection. We measured responses to DENV peptides using an IL-2/IFN-γ dual color enzyme-linked immunospot (ELISPOT) assay. Peripheral blood mononuclear cells (PBMC) from Thai children prior to and after secondary DENV-1 and DENV-2 infection from a 5-year prospective cohort study were stimulated with overlapping peptide pools of structural and non-structural proteins from the four DENV types. Overall, responses to DENV peptides demonstrated a cytokine phenotype hierarchy of IFN-γ > IL-2 > IFN-γ/IL-2. Responses to DENV peptides were low or absent prior to secondary infections. Subjects who experienced a secondary DENV-1 infection showed higher cytokine responses post-infection compared to secondary DENV-2 or subjects with subclinical infections. The trends in responses to DENV peptides over 3 y post-infection were highly variable. These data demonstrate a lasting but variable impact of secondary DENV infection on DENV-specific T cell responses.

HIGH THROUGHPUT LIVE-IMAGE CYTOMETRY-BASED NEUTRALIZATION ASSAYS FOR DENGUE AND ZIKA VIRUSES

Karen L. Boroughs, Yee Tsuey Ong, Kimberly M. Anderson, Janae L. Stovall, Elizabeth A. Dietrich, Claire Y. H. Huang

Centers for Disease Control and Prevention, Fort Collins, CO, United States

Virus neutralization tests such as plaque and micro-focus reduction neutralization tests (PRNT and mFRNT) are critical tests in flavivirus diagnosis, vaccine study, and sero-surveillance. Since Zika virus (ZIKV) and dengue viruses (DENVs) co-circulate in areas with *Aedes* mosquitoes, simultaneous NT for ZIKV and DENV is usually required. Wild-type DENV and ZIKV replicate slowly, making PRNT time-consuming. Previously, we developed West Nile virus (WNV)-based chimeric DENV 1-4 and ZIKV, which reduced the duration of traditional PRNT and mFRNT by 50%. To further improve and streamline the assay, we developed live chimeric reporter DENVs and ZIKV (R-WN/DENVs and R-WN/ZIKV) expressing green fluorescent protein in infected cells that can be automatically analyzed by cytometer or fluoro-spot reader. The chimeric reporter virus seed lots used for NT assay were evaluated by RT-PCR and flow cytometry to confirm 100% reporter gene integrity of the reporter viruses. Using these reporter viruses, we developed a reporter-mFRNT (R-mFRNT) which can be measured within 24-30 hours after cell infection. Using human clinical sera, we verified the neutralization Ab titers obtained from the R-mFRNT were identical or similar to titers obtained by traditional PRNT or mFRNT. Due to the use of same WNV-based chimeric platform, all the reporter viruses have similar replication efficiency and provide a fast and practical means to obtain NT results to ZIKV and DENVs simultaneously. In addition, the live-image based R-mFRNT allows for a true high-throughput detection directly from cell culture without any cell fixation or other additional procedures.

902

PUBLIC HEALTH IMPACT OF VACCINATION WITH DENGVAXIA IN THE PRESENCE OF INTRA-URBAN VARIATION IN DENGUE VIRUS TRANSMISSION

Magdalene K. Walters, T. Alex Perkins

University of Notre Dame, Notre Dame, IN, United States

Dengvaxia from Sanofi Pasteur is currently the only licensed dengue vaccine. Results from phase-III trials indicate that people with no history of natural dengue virus (DENV) infection who receive Dengvaxia experience an elevated risk for severe disease upon subsequent natural infection. This finding has shed light on the importance of spatial variation in

DENV transmission history, with this vaccine only recommended for use in areas with a high probability of prior DENV infection among potential vaccinnees. This recommendation has prompted efforts to measure DENV transmission intensity through the analysis of serological survey data. However, DENV transmission is known to be highly spatially heterogeneous, even at intra-urban scales. We performed a modeling analysis to understand whether spatial aggregation of serological data at the scale of a city could lead to unintended harm in the presence of spatial heterogeneity in DENV transmission below the scale of the city as a whole. We used a modified SIR model that allows for up to four distinct DENV infections over a person's lifetime to examine the differential impacts of vaccination on two sub-city communities with different transmission intensities but connected by human mobility. Vaccination coverage of 80% led to a decrease in the number of cases on a city-wide scale and had varied effects on a sub-city scale. It was found that under uniform vaccination across two districts of the city with differential transmission intensity, the district characterized by low transmission had an increase in the incidence of severe disease while the district characterized by high transmission had a decrease in the number of infections. This work has implications for vaccination campaigns in cities in which there is spatial heterogeneity in transmission that is unaccounted for in the aggregation of serological data at a city-wide scale.

903

SPATIOTEMPORAL VARIATION IN DENGUE TRANSMISSION INTENSITY IN JAKARTA, INDONESIA

Megan O'Driscoll[1], Natsuko Imai[1], Neil Ferguson[1], Sri Rezeki Hadinegoro[2], Hindra Irawan Satari[2], Clarence C. Tam[3], Ilaria Dorigatti[1]

[1]Imperial College London, London, United Kingdom, [2]Universitas Indonesia, Jakarta, Indonesia, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom

The characterisation of both spatial and temporal variation in dengue transmission intensity is of key importance for optimal implementation of new control and prevention strategies, including vaccination programmes and the release of *Wolbachia*-infected mosquitoes. Large seroprevalence surveys are often unfeasible due to the associated costs, placing reliance on disease surveillance data for assessment of local dengue epidemiology. Though the quality of dengue disease surveillance data is often uncertain due to lack of laboratory-confirmation and unspecific clinical manifestations, analysis of the relationship between age and the observed disease incidence can provide valuable insights into the underlying nature of dengue transmission. Jakarta, the capital of Indonesia, a dengue hyperendemic country, has a population of over 10 million people. In Jakarta, clinically-confirmed, hospitalized cases of dengue haemorrhagic fever (DHF) are reported to the epidemiological surveillance system and reported online. We used a mathematical model in a Bayesian inferential framework to estimate dengue force of infection, basic reproduction number, and reporting probabilities from age-stratified dengue case-notification data for 44 sub-districts (administrative level 3) in Jakarta over a 10-year period, 2008-2017. We assumed all 4 dengue serotypes to be in circulation and equally transmissible. The model was used to explore varying assumptions about the contribution of primary, secondary and post-secondary dengue infections to the observed disease incidence. Under the simplest assumption that only secondary infections contribute to the observed disease incidence, the average annual force of infection in Jakarta was estimated at 9.7% (97.5%CrI: 9.6-9.8%) for the 10-year period. This ranged from an average of 6.3% to 13.2% per year between sub-districts. Further model extensions allowing for all (primary-quaternary) dengue infections to contribute to the observed disease incidence will allow further characterisation of the spatial and temporal distribution of dengue transmission in Jakarta.

904

INCREASED SIALIC ACID LEVELS IN SERUM ARE ASSOCIATED WITH VASCULAR LEAK AND SEVERE DENGUE DISEASE

Diego A. Espinosa[1], Henry Puerta-Guardo[1], P. Robert Beatty[1], Nurul Islam[2], John T. Belisle[2], Angel Balmaseda[3], Rushika Perera[2], Eva Harris[1]

[1]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, [2]Department of Microbiology, Immunology and Pathology, Colorado State University, Fort Collins, CO, United States, [3]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministry of Health, Managua, Nicaragua

With an estimated 400 million infections and approximately 100 million cases each year, dengue is the most common arboviral infection. Infection with any of the four dengue virus (DENV1-4) serotypes results in a spectrum of outcomes, from asymptomatic infection to classic dengue fever (DF) to dengue hemorrhagic fever/dengue shock syndrome (DHF/DSS), characterized by vascular leakage and shock. Previous research has established that DENV non-structural protein 1 (NS1) directly induces endothelial hyperpermeability *in vitro* and vascular leak *in vivo.* Further, our group demonstrated that DENV NS1 disrupts the endothelial glycocalyx layer (EGL) *in vitro,* triggering the degradation and shedding of key structural components, including sialic acid and heparan sulfate proteoglycans. In addition, studies in human populations have shown that increased levels in serum of EGL components such as hyaluronic acid, heparan sulfate and syndecan-I are associated with plasma leakage and severe dengue disease. Here, using a murine model of DENV-induced vascular leak, we demonstrate that sialic acid and NS1 levels in circulation correlate with increasing viral inoculum and DENV-induced morbidity and are significantly higher ($p=0.0026$ for sialic acid and $p<0.0001$ for NS1) in mice that succumb to DENV infection. Additionally, preliminary experiments using liquid chromatography-mass spectrometry (LC-MS) indicate that free sialic acid levels in human serum samples from dengue studies in Nicaragua are significantly elevated in DSS cases. Overall, the identification of novel biomarkers of infection severity, such as sialic acid, can improve triage of severe dengue cases and may provide important insights into mechanisms of DENV pathogenesis and contribute to the development of new therapies.

905

HERD IMMUNITY TO ZIKA VIRUS MAY CAUSE CHANGES IN THE DYNAMICS OF DENGUE INCIDENCE IN THE AMERICAS

Vanio A. Mugabe[1], Lairton S. Borja[2], Cristiane W. Cardoso[3], Uriel C. Kitron[4], Mitermayer G. dos Reis[2], Guilherme S. Ribeiro[2]

[1]Instituto de Saude Coletiva - Universidade Federal da Bahia, Brasil, Salvador, Brazil, [2]Oswaldo Cruz Foundation (FIOCRUZ), Salvador, Brazil, Salvador, Brazil, [3]Secretaria Municipal de Saúde de Salvador, Salvador, Brazil, Salvador, Brazil, [4]Emory University, Atlanta, GA, United States

We have previously suggested that Zika virus (ZIKV) immunity may afford protection to dengue virus (DENV) infection. This hypothesis was raised based on analysis of long-term surveillance data showing a substantial reduction in dengue case detection after the ZIKV epidemics in Salvador, Brazil. We have therefore undertaken a broader explorative investigation covering DENV-endemic American countries that have recently undergone ZIKV epidemics to assess whether they also presented a decline in dengue occurrence. We analyzed the historical series (2008 to 2017) of dengue cases reported to World Health Organization (WHO) and Pan American Health Organization (PAHO) for the 12 countries with autochthonous ZIKV transmission in 2015, and with available dengue count data for the period (Brazil, Colombia, El Salvador, French Guiana, Guatemala, Honduras, Martinique, Mexico, Panama, Paraguay, Puerto Rico, and Venezuela). In the post-ZIKV period (2016-2017), dengue reported cases declined in 11 of the 12 countries, with Panama, where the number of cases increased, being an exception. Prior to the ZIKV epidemics, all countries displayed a

pattern of periodic oscillations of number of dengue cases over time, with each cycle lasting 1-3 years. In three countries (Puerto Rico, Martinique, and French Guiana), the number of dengue cases began to decline before 2015, and remains low for >3 years now, making it the longest sequence of years with low occurrence of dengue cases detected in this historical series. For other countries, such as Brazil, Puerto Rico, and Venezuela, the number of reported dengue cases in 2017 was the lowest reported since 2008. Although our analysis uses secondary, countrywide data (which may not reflect the true picture for each country due to reporting errors or absence of spatial overlap between ZIKV and DENV transmission within each country), our findings do corroborate the hypothesis that ZIKV epidemics may play a role in the dynamics of dengue occurrence in the Americas. Further long-term prospective follow-up of dengue reports are needed to confirm these findings and to assess whether they represent a long-lasting phenomenon.

906

FLAVIVIRUS NS1 INDUCES ENDOCYTOSIS AND PHOSPHORYLATION OF TIGHT AND ADHERENS JUNCTION PROTEINS, LEADING TO ENDOTHELIAL BARRIER DYSFUNCTION

Henry Puerta-Guardo[1], Jeffrey Shu[1], Julio Gallego-Delgado[2], Dustin R. Glasner[1], Nori Ueno[3], Melisssa Lodoen[3], Ana Rodriguez[2], Eva Harris[1]

[1]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, [2]Parasitology Division, Microbiology Department, New York University School of Medicine, New York, NY, United States, [3]Department of Molecular Biology & Biochemistry, University of California Irvine, Irvine, CA, United States

Flaviviruses cause systemic or neurotropic-encephalitic pathology in humans. Recently, we showed that nonstructural protein 1 (NS1) from different flaviviruses causes endothelial barrier dysfunction and vascular leakage in a tissue-dependent manner. This phenomenon depends in part on the integrity of the endothelial glycocalyx layer (EGL) lining the surface of endothelial cells. Besides the EGL, tight and adherens junctions (TJ/AJ) also help maintain endothelial barrier function. Here, we investigate the relative contribution of TJ/AJ proteins to the increased barrier dysfunction caused by different flavivirus NS1 proteins from dengue (DENV), Zika (ZIKV), West Nile (WNV), Japanese encephalitis (JEV), and yellow fever (YFV) viruses on human placenta (HUVEC) and brain (HBMEC) endothelial cells. Six hours post-treatment, only DENV and ZIKV NS1 proteins altered the normal distribution of ZO-1, VE-cadherin, and β-catenin in HUVEC monolayers, as determined by immunofluorescence assay. However, in HBMEC, this distribution was affected by all flavivirus NS1 proteins but YFV NS1. Western blot analyses showed no significant changes in expression of TJ/AJ proteins in both endothelial cell lines after NS1 treatment, except that DENV NS1 in HUVEC and WNV NS1 in HBMEC significantly reduced the expression of ZO-1. These results suggest that flavivirus NS1 proteins disrupt the integrity of TJ/AJ proteins by either altering their normal localization in the cell-to-cell contacts or reducing their expression. Mechanistically, we found that DENV NS1 induces clathrin/dynamin-dependent endocytosis of ZO-1 and VE-cadherin, as well as phosphorylation of β-catenin (Ser45) by CK-1 and GSK-3β kinases, resulting in the remodeling of the intercellular junction complex. Specific inhibitors of clathrin- and dynamin-dependent endocytosis and inhibitors of GSK-3β activity abrogated NS1-induced permeability of HUVEC monolayers, indicating that these mechanisms are also involved in the NS1-induced endothelial dysfunction. These findings add new insights into the modulation by flavivirus NS1 proteins of endothelial barrier function.

907

TRACKING THE POLYCLONAL NEUTRALIZING RESPONSE TO A DENV1 SEROTYPE-SPECIFIC EPITOPE ACROSS TWO POPULATIONS IN ASIA AND THE AMERICAS

Daniela V. Andrade[1], Douglas Widman[2], Ellen Young[2], Aravinda de Silva[3], Ralph Baric[2], Eva Harris[1]

[1]Division of Infectious Diseases & Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, [2]Department of Epidemiology, University of North Carolina School of Public Health, Chapel Hill, NC, United States, [3]Division of Infectious Diseases, University of North Carolina, Chapel Hill, NC, United States

Recent advances in the characterization of human antibody responses to primary dengue virus (DENV) infection indicate that highly neutralizing type-specific (TS) antibodies target quaternary epitopes on the DENV envelope protein. Within this class of potent TS neutralizing antibodies is 1F4, isolated from a donor with a primary DENV1 infection. Given the high neutralization capacity of 1F4, we created a recombinant DENV2 containing the 1F4 epitope (rDENV2/1) via structure-guided immunogen design and reverse genetics. Here, we use the rDENV2/1 chimeric virus to measure the proportion and kinetics of DENV1 TS neutralizing antibody (nAb) responses targeting this epitope in individuals living in two dengue-endemic areas. We analyzed convalescent sera of 10 individuals with primary DENV1 infection in Nicaragua and 10 in Sri Lanka to determine the prevalence and proportion of the DENV1 nAb response attributable to the 1F4 epitope. The nAb titers (NT_{50}) to the rDENV2/1 virus and its parental DENV1 and DENV2 viruses were obtained via a flow cytometry-based neutralization assay using human monocytic U937-DC-SIGN cells. To evaluate the kinetics of the nAb response to the 1F4 epitope, we analyzed samples collected 3 and 18 months post-infection from the same 10 individuals enrolled in a longitudinal dengue hospital-based study in Nicaragua. In preliminary data from the Nicaraguan and Sri Lankan populations, the polyclonal responses of 80% (8/10) and 90% (9/10) individuals, respectively, track to various degrees with the 1F4 epitope. The average proportion of the DENV1 nAb response attributable to the 1F4 epitope was 36% (3 months) and 56% (18 months) in Nicaraguan and 55% (1 month) in Sri Lankan samples. Longitudinal samples from additional individuals in Nicaragua are being analyzed from the hospital study as well as a cohort study over 4 years post-infection. Characterization of epitope-specific nAb responses in natural DENV infections in Asian and American populations can help elucidate the antibody repertoire to DENV epitopes, with implications for vaccine design.

908

EPIDEMIOLOGY OF DENGUE IN INDIA - OUTCOME OF A FACILITY BASED ACUTE FEBRILE ILLNESS (AFI) SURVEILLANCE

Govindakarnavar Arunkumar[1], Robin S[1], Aswathyraj Sushama[1], Sasidharan Pillai Sabeena[1], Santhosha Devadiga[1], Sudheesh Nair[1], Jazeel Abdulmajeed[1], Anup Jayaram[1], Prasad Varamballi[1], Revti Bhaskar[1], Chaithra Rao[1], Suresh Prabhu[1], Shahin Sheik[1], Yuvraj Bhandari[1], Hiren G Dodia[1], Mohan Papanna[2], Prabeen Kumar Sen[3], Jagdish Prasad[4], Kayla F. Laserson[2]

[1]Manipal Academy of Higher Education, Udupi, Karnataka, India, [2]U.S. Centers for Disease Control and Prevention, India Office, New Delhi, India, [3]National Vector Borne Disease Control Programme (NVBDCP), MOHFW, New Delhi, India, [4]Directorate General of Health Services, MOHFW, New Delhi, India

Dengue is a major public health problem potentially affecting 50 million people worldwide. The epidemiology of dengue in India is complex and has substantially changed over the years in terms of circulating serotypes, severity, and geographic spread. As the available data regarding dengue is mostly from tertiary care settings, through the Global Health Security supported hospital-based acute febrile illness (AFI) surveillance in India, we

tested all consenting eligible AFI cases for viruses, bacteria and parasites in 32 district / sub-district hospitals across 10 states. We enrolled in-patients with documented or reported fever <15 days duration and collected demographic, clinical, and epidemiological data; we also collected blood samples. A case with either NS1Ag ELISA, IgM ELISA, PCR positivity in acute or IgM /IgG seroconversion in convalescent serum was defined as dengue. We enrolled 27,431 patients between June 2014 to July 2017 and 14,134 (51.5%) had a definitive diagnosis. The major etiologies were influenza (16.6%), dengue (9.7%), scrub typhus (8.6%), leptospirosis (8.1%), malaria (4.7%) and KFD (2.2%). The percentage dengue positivity among AFI cases varied by state from 1.7 to 18.6 and was highest in Tamilnadu (18,6%), Assam (14.4%) and Kerala (9.9%). Based on presence of IgG antibodies in acute serum, 43% cases were secondary dengue. As per WHO classification, 10% had severe dengue, 25% had warning signs. The median age was 26 years (IQR: 17, 38) and 60% were male. Predominant clinical symptoms included abdominal pain (27.5%), retro-orbital pain (30.2%), and rash (1.2%). Thrombocytopenia was evident in 44.6% cases. Referral to higher centres occurred in 159 (6.5%) cases and 3 cases died. Circulating dengue virus serotypes were DENV1, DENV2, and DENV3. Dengue was prevalent throughout the year with increased activity May to December. Prevalence of dengue among AFI cases varied geographically and multiple serotypes co-circulated. Availability of diagnostic facilities at district / sub district hospitals may lead to more rapid diagnosis and these data can be used to help develop clinical guidelines for managing AFI cases in India.

909

THE RISING IMPACT AND COMPLEX ECOLOGY OF DENGUE IN RURAL MALAYSIA

Amanda Murphy[1], Jenarun Jilip[2], Timothy William[2], Marilyn Maluda[2], Giri S. Rajahram[2], Simon Reid[3], Wenbiao Hu[4], Gregor J. Devine[1], Francesca D. Frentiu[4]

[1]QIMR Berghofer Medical Research Institute, Brisbane, Queensland, Australia, [2]Sabah Department of Health, Kota Kinabalu, Sabah, Malaysia, [3]University of Queensland, Brisbane, Queensland, Australia, [4]Queensland University of Technology, Brisbane, Queensland, Australia

In South East Asia, dengue epidemics have increased in size and geographical distribution in recent years. In Malaysia, regular outbreaks occur across the country, causing significant morbidity and economic burden. While the majority of control efforts have focused on preventing dengue in urban areas, transmission dynamics are poorly understood in more rural states, or where urban and rural areas overlap. This study examined the epidemic characteristics and spatiotemporal distribution of reported dengue cases in the predominantly rural state of Sabah, in Malaysian Borneo. Our analyses of state-wide notification data over a 7-year period (2010-2016) indicated wide variability in the pattern of high-risk clusters detected over space and time, with a mean annual incidence rate of 49/100,000 people. The largest ever recorded outbreaks occurred in both urbanised cities and rural villages from late 2014 to 2016. The highest incidence rates were in people aged between 10-49 years, with a median age of 25. Severe dengue cases were geographically localised to two administrative divisions in the eastern area of the state: Tawau and Sandakan. Active surveillance of dengue case residences during the outbreaks identified the typically sylvatic vector mosquito *Aedes albopictus* as the dominant species breeding in all locations (comprising 65% of larvae identified in case residences). Our findings challenge the notion that human population density is the primary driver of dengue disease patterns, and provide a platform to further assess the complex interplay of local and regional climatic, ecological and anthropogenic factors that underlie dengue risk.

910

DISCRETE PHENOTYPIC SIGNATURES OF CD8+ T CELLS DURING DENGUE VIRUS INFECTION

Melissa Chg[1], Lim Mei Qui[2], David Lye[3], Yee Sin Leo[3], Paul MacAry[4], Evan Newell[1], **Laura Rivino**[2]

[1]Singapore Immunology Network, Singapore, Singapore, [2]Duke-NUS Medical School, Singapore, Singapore, [3]Tan Tock Seng Hospital, Singapore, Singapore, [4]National University of Singapore, Singapore, Singapore

Dengue virus (DENV), a mosquito-borne flavivirus, is estimated to cause up to 390 million infections per year, of which 100 million cases are symptomatic. The recently approved dengue vaccine has demonstrated only partial protection, despite optimal induction of neutralizing antibodies towards all DENV serotypes, thus highlighting the need for an improved definition of the correlates of protective immunity towards DENV. In particular, the nature and role of DENV-specific T cells remain unclear. Initial studies suggested a contribution of suboptimal cross-reactive CD8+ T cell responses to the development of severe disease during secondary infection. In contrast, more recent work suggests a key protective role of a vigorous DENV-specific T cell response restricted to "protective" HLA alleles. To better define the nature of the dengue-specific T cell response restricted to HLA molecules that are commonly expressed in South-East Asia, we performed an in-depth study of dengue-specific CD8+ T cells restricted to HLA-B*58:01, HLA-A*24:02 and HLA-A*11:01 using multiplex combinatorial tetramer staining and Time of Flight Mass Cytometry (CyTOF). T cells specific for >100 distinct epitopes from DENV 1-4, Epstein-Barr virus (EBV) and Influenza virus (Flu) were simultaneously analyzed for expression of 30 phenotypic and functional T cell markers during acute, post-febrile and convalescent dengue infection. High-dimensional phenotypic profiling reveals a distinctive and highly homogenous signature of DENV-specific T cells during acute infection, which was not affected by HLA restriction or epitope immunodominance. In contrast, at convalescence DENV-specific T cells diverged into T cells with two opposing phenotypic signatures characterized either by high expression of markers of terminal differentiation or of markers suggesting long-term memory persistence, the latter cells resembling those specific for EBV and Flu. Current efforts in our laboratory are aimed at investigating the influence of antigenic exposure in primary versus secondary dengue infection in driving these two opposing memory T cell signatures.

911

A NOVEL PROSPECTIVE FAMILY COHORT STUDY OF DENGUE VIRUS TRANSMISSION IN KAMPHAENG PHET, THAILAND BASELINE IMMUNOLOGICAL AND SUBCLINICAL SEROCONVERSIONS FROM THE FIRST YEAR

Darunee Buddhari[1], Kathryn B. Anderson[2], Greg Gromowski[3], Richard G. Jarman[3], Sopon Iamsirithaworn[4], Anon Srikiatkhachorn[5], Alan L. Rothman[5], Alden L. Weg[1], Damon W. Ellison[1], Louis R. Macareo[1], Stephen J. Thomas[6], Timothy P. Endy[6]

[1]U.S. Army Medical Directorate-Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [2]University of Minnesota, Minneapolis, MN, United States, [3]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [4]Ministry of Public Health, Nonthaburi, Thailand, [5]University of Rhode Island, Providence, RI, United States, [6]State University of New York, Syracuse, NY, United States

We describe results from the first year of a novel prospective study in Kamphaeng Phet, Thailand, which follows multigenerational family units for dengue virus (DENV) infection over several years. 368 families (2428 individuals) were enrolled between September 2015 and June 2016 with a median of 6 individuals per family and an age range of 0 to 93 years (median 21 years). Each family comprised of at least a pregnant female, her newborn child, one child aged below 18 years old, and one grandparent. Blood specimens were collected at enrollment; 73 families (416 individuals) underwent a first scheduled follow up blood collection

in mid-2016 (7-9 months post-enrollment). Flow-based neutralization antibody testing (FlowNT50) was used to characterize baseline serological profiles and to detect seroconversions, defined as a ≥3-fold rise in titer to one or more DENV type. Among newborns (as measured in cord blood), 85.9% had multitypic profiles, 2.8% monotypic, and 11.3% had no detectable DENV antibodies. Baseline seropositivity to DENV was lowest in children aged 0 to 5 years (26.8% multitypic, 19.5% monotypic, and 53.7% DENV-naïve). Above 30 years of age, 100% of individuals had multitypic DENV profiles. 53 seroconversions were identified by comparison of FlowNT50 titers from scheduled specimens, for a seroconversion rate of 12.7%. There was significant clustering of seroconversions within family units ($p<0.01$ by χ^2 testing) and, among families with one or more seroconversions, the median seroconversion rate was 25% (range: 8.3-100%). The maximum seroconversion rate was observed in individuals aged 16-20 years (34%), followed by children aged 0 to 5 years (20%). The lowest seroconversion rate was in adults aged 31-50 years (3%). This study demonstrates ongoing high incidence of DENV infection in north-central region of Thailand with clustering at the household level and continued risk affecting all ages.

912

EPIDEMIOLOGICAL SIGNIFICANCE OF DENGUE VIRUS GENETIC VARIATION IN MOSQUITO INFECTION DYNAMICS

Albin Fontaine[1], Sebastian Lequime[2], Isabelle Moltini-Conclois[1], Davy Jiolle[1], Isabelle Leparc-Goffart[3], Robert C. Reiner[4], **Louis Lambrechts**[1]

The kinetics of arthropod-borne virus (arbovirus) transmission by their vectors have long been recognized as a powerful determinant of arbovirus epidemiology. The time interval between virus acquisition and transmission by the vector, termed extrinsic incubation period (EIP), combines with vector mortality rate and vector competence to determine the proportion of infected vectors that eventually become infectious. However, the dynamic nature of this process, and the amount of natural variation in transmission kinetics among arbovirus strains, are rarely taken into account in epidemiological models. Here, we combine empirical measurements *in vivo* and outbreak simulations *in silico* to assess the epidemiological significance of genetic variation in dengue virus (DENV) transmission kinetics by *Aedes aegypti* mosquitoes. We found significant variation in the dynamics of systemic mosquito infection, a proxy for EIP, among eight field-derived DENV isolates representing the worldwide diversity of recently circulating type 1 strains. Using a stochastic agent-based model to compute time-dependent individual transmission probabilities, we predict that the observed variation in systemic mosquito infection kinetics drives significant differences in the probability of dengue outbreak and the number of human infections. Our results demonstrate that infection dynamics in mosquitoes vary among wild-type DENV isolates and that this variation can contribute to the risk and magnitude of dengue outbreaks. Our quantitative assessment of DENV genetic variation in transmission kinetics contributes to improve our understanding of heterogeneities in arbovirus epidemiological dynamics.

SPATIOTEMPORAL HETEROGENEITY OF DENGUE TRANSMISSION INTENSITY IN COLOMBIA

Natsuko Imai[1], Benjamin Jeffrey[1], Zulma M. Cucunubá[1], Marcela Mercado[2], Franklyn Prieto[2], Martha Ospina[2], Neil M. Ferguson[1], Ilaria Dorigatti[1]

[1]Imperial College London, London, United Kingdom, [2]Instituto Nacional de Salud, Bogota, Colombia

With the rapid development of new dengue control options, such as the release of *Wolbachia*-infected mosquitoes and a second-generation of dengue vaccines, characterising dengue transmission intensity at fine spatiotemporal resolution is essential for the optimal design of control programmes. Serological studies are considered the gold standard to quantify dengue transmission intensity as they capture both symptomatic and asymptomatic infections. However, they are often expensive to conduct and hence not widely available. Previously, we have shown that dengue transmission intensity can be inferred by fitting catalytic models to age-stratified case notification data, and that these estimates are largely comparable to those obtained from seroprevalence data. Here we apply these methods to estimate the average and time-varying dengue force of infection and reporting probabilities from age-stratified case-notification data reported to National Institute of Health Colombia in 2010-2016. Analysis was conducted at the first and second administrative unit levels (department and district-level, respectively). We found large spatial and temporal heterogeneity in transmission intensity within and between departments, with the highest transmission intensity clustered in the North and Central-Western parts of Colombia. The estimated variation in transmission intensity at small spatial scales suggests that future control measures may need to be targeted at the district rather than the department level. Reporting rates also varied substantially between and within departments, suggesting differences in healthcare accessibility, coverage and health-seeking behaviour. Although additional, currently ongoing analyses are needed to calibrate force of infection estimates obtained from serological data with those obtained from case-notification data, routinely collected age-stratified dengue incidence data represent a valuable source of information and a unique opportunity to quantify global and local trends in dengue transmission intensity.

914

COMPARISON OF CLINICAL MANIFESTATIONS AND DISEASE CLASSIFICATION OF ADULT AND PEDIATRIC DENGUE IN A PROSPECTIVE STUDY OF HOSPITALIZED DENGUE IN THAILAND

Anon Srikiatkhachorn[1], Darunee Buddhari[2], Alden L. Weg[2], Kamchai Rungsimanphaiboon[2], Angkhana Ouppapong[3], Surachai Kaewhiran[3], Janya Chaisirirat[3], Damon W. Ellison[2], Louis R. Macareo[2], Alan L. Rothman[1], Sharone Green[4]

[1]University of Rhode Island, Providence, RI, United States, [2]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [3]Kamphaeng Phet Provincial Hospital, Kamphaeng Phet, Thailand, [4]University of Massachusetts Medical School, Worcester, MA, United States

Although dengue is considered a childhood disease recent evidence has demonstrated increasing numbers of adult dengue. Comparisons across studies have reported differences in clinical features of adult and pediatric dengue. However, these differences may be due to other factors, such as virus transmission and host genetic differences. To better define characteristics of dengue in adults and children in the same geographical location, we conducted a prospective study of hospitalized suspected dengue cases in Kamphaeng Phet, Thailand. Suspected dengue cases were enrolled and their daily clinical, laboratory, and imaging information was collected following a standardized protocol. Between March 2016 and September 2017 seventy-nine cases were enrolled, 64 were confirmed dengue cases: 24 adults, 40 children. The mean ages of the adults and the children were 29.1 (2.6) and 11.5 (.5) years, respectively. Nine (37.5%), 6 (25%), and 9 (37.5%) of adults were diagnosed with dengue fever (DF), dengue hemorrhagic fever (DHF) grade I, and DHF grade II. Twenty six (65%), 7 (17.5%), 6 (15%), and 1 (2.5%) of children had DF, DHF grade I, grade II, and grade III. Classification using the World Health Organization 2009 scheme resulted in 50%, 42%, 8% of adults, and 35%, 62.5%, 2.5% of children diagnosed as dengue (D), dengue with warning signs (DWS), and severe dengue (SD), respectively. A significant correlation between the diagnosis of DHF and DWS/SD was observed in children but not in adults. The enrollment clinical findings that were associated with the diagnosis of DHF or DWS/SD were abdominal pain in both adults and children. Only 33% of adult DHF cases had evidence of hemoconcentration (defined as at least a 20% increase in

hematocrit) compared to 71.4% of children with DHF and the degree of hemoconcentration was significantly lower (18% in adults and 28.6% in children). These findings suggest that adult and pediatric dengue have different clinical features and disease progression and that the current case classification and management schemes which were developed primarily from children are not ideal for adults with dengue.

915

NK CELL DEGRANULATION ASSAY FOR ASSESSING DENGUE VIRUS SPECIFIC ANTIBODY-DEPENDENT CELLULAR CYTOTOXICITY ELICITING ANTIBODIES IN INFECTED AND VACCINATED INDIVIDUALS

Jeffrey R. Currier[1], Vihasi Jani[2], Nishith Nagabhushana[2], Heather Friberg[1], Maya Williams[2], Richard Jarman[1], Peifang Sun[2], Brian J. Morrison[2]

[1]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]Naval Medical Research Center, Silver Spring, MD, United States

Clinical development of a safe and efficacious dengue vaccine is a DoD force health protection priority. Traditionally, it was assumed that dengue vaccine efficacy would correlate with neutralizing antibody (NAb) titers. However, recent data from Phase II/III trials of a DENV vaccine product demonstrate a discordance of vaccine efficacy with NAb titers. Therefore, the development and testing of alternative assays for measuring and assessing functional antibody activity against dengue virus is warranted. The aim of this study was to assess cellular opsonization and develop an ADCC assay based on the level of NK cell degranulation elicited using DENV-infected CEM-NK^R-DC-SIGN cells (targets). CEM-NK^R-DC-SIGN cells are resistant to non-ADCC NK cell killing, devoid of surface FcRs, and permissive to DENV infection. CEM-NK^R-DC-SIGN target cells demonstrated permissiveness to all four DENV serotypes and surface expression of low levels of structural proteins and high levels of NS1. These cells also demonstrated opsonization with IgG from the sera of DENV-infected subjects. Opsonized target cells were then co-incubated with PBMCs (at 1:1 Effector: Target ratio) isolated from a healthy donor and consequently stained with an antibody cocktail (APC-CD56, PerCP-CD3, FITC-CD107a, and PE-CD16). The expression of CD107a, which correlates with both cytokine secretion and NK cell-mediated lysis of target cells, was used to assess degranulation and determine an ADCC-Ab titer. The assay was then used to assess vaccine-induced ADCC activity in the context of the TDEN-001 LAV/LAV (WRAIR #1151) vaccine trial. We determined that opsonization and antibody-dependent NK cell degranulation increased dramatically following receipt of the vaccine for all four serotypes of DENV. Assessing vaccine-induction of these different types of Ab are critical for understanding the full breadth of the immune response directed against DENV. This study demonstrates the utility of the CEM.NK^R-DC-SIGN cells as target cells to assess serum Ab activity capable of eliciting ADCC and other responses.

916

ANTIGEN-SPECIFIC B CELL ACTIVATION AFTER IMMUNIZATION WITH A TETRAVALENT DENGUE PURIFIED INACTIVATED VACCINE (DPIV)

Heather Friberg[1], Anuja Mathew[2], Morgan Becker[1], Kristin Hatch[1], Amanda Kong[1], Kaitlin Victor[1], Richard G. Jarman[1], Robert Paris[3], Alexander C. Schmidt[3], Stephen J. Thomas[1], Philippe Moris[4], Jeffrey R. Currier[1]

[1]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]University of Rhode Island, Providence, RI, United States, [3]GSK, Rockville, MD, United States, [4]GSK, Rixensart, Belgium

Dengue is a growing global health issue for which development of a protective vaccine has proven challenging. While neutralizing antibodies (NAbs) are thought to contribute to protection from disease, dengue infection still occurs in some individuals with measurable NAb titers. It is therefore postulated that both NAbs and cell-mediated responses are important for the generation of protective immunity. In a previously described Phase 1 study of a tetravalent dengue purified inactivated vaccine (DPIV) candidate (NCT01666652), we demonstrated the persistence of dengue-specific memory B cells up to 1 year post-vaccination despite waning NAb titers. Here we present data on vaccine-induced plasmablasts (PBs) and use fluorescently-labeled viruses to track antigen-specific cells in the periphery in a subset of subjects given a third booster dose of either the 1µg+AS01$_E$ (n=6) or the 4µg+Alum formulations (n=3). We observed robust expansion of these cells 7 days post-vaccination with discernible, multivalent binding of fluorescent viruses, which revealed a more distinct population compared to phenotyping PB alone. Freshly isolated peripheral blood mononuclear cells (PBMCs) were comparable to cryopreserved PBMCs with respect to the frequency of PBs detectable by ELISPOT, although spot size was notably smaller after cryopreservation. Isolated PBs were analyzed using Atreca's Immune Repertoire Capsule technology. Examination of over 500 heavy and light chain antibody pairs per subject revealed similar levels of overall somatic hypermutation between the two different vaccine formulations, although the antibody sequences with the highest mutation levels were observed in 1µg+AS01$_E$ recipients. Evidence of usage bias for particular heavy chain V genes was observed with minor differences between the two different vaccine groups. IgG1 was the most predominant IgG subclass used amongst isolated PBs, and similar levels of repertoire diversity were also noted. Overall, DPIV vaccination induced a distinct antigen-specific PB response. Future analyses to determine correlations of the PB response to memory B cell and NAb responses are planned.

917

THE IMPACT OF WEATHER ON THE SPATIO-TEMPORAL TRANSMISSION DYNAMICS OF DENGUE ACROSS SOUTH EAST ASIA

Robert C. Reiner[1], Moritz Kraemer[2], Alex Perkins[3], Derek Cummings[4]

[1]University of Washington, Seattle, WA, United States, [2]Harvard Medical School, Boston, MA, United States, [3]Notre Dame, South Bend, IN, United States, [4]University of Florida, Gainesville, FL, United States

Drivers of mosquito population dynamics have significant impact on the transmission of Dengue virus. Climatic variables, such as temperature, influence the development and survival of mosquitoes in complex and non-linear ways, which in turn influences ongoing transmission. Standard approaches to incorporate weather into transmission models identify, for each weather variable, at most a few lags by which to stagger the relationship between the climatic driver and transmission dynamics. Distributed lag non-linear models (DLNM) allow for the assessment of all possible non-linear lagged relationships within a single framework. Here, we combined a DLNM and a generalized additive model to adjust for seasonality within a TSIR transmission framework to assess the influence of weather on monthly dengue transmission from 1993 to 2010 across 300 locations within 8 countries in South East Asia. We found significant impact of day and night temperature, precipitation, humidity, total column water vapor, and enhanced vegetation index. Due to collinearity in these drivers, we analyzes their impacts in isolation and in parallel. The univariate analyses were able to recreate some expected relationships such as the inverted-U shaped relationship between temperature and transmission. Interestingly, other drivers' influence on transmission was not as straightforward, with, for example, heavy rainfall being both bad for transmission in the near past, but also beneficial a month before. The final model that incorporated all the significant distributed lag effects explained 76% of the variance in the case data. Dengue transmission is both local and focal, and even in hyperendemic locations, poorly predicted. Accurately quantifying the role of extrinsic drivers such as weather is a vital step to understanding when and where an outbreak is most likely. The models presented here have many applications from correctly understanding the expected number of cases during control trials to targeted interventions during a dengue season.

918

NATIONALLY REPRESENTATIVE SEROSTUDIES FROM BANGLADESH SHOW LARGE-SCALE HETEROGENEITY IN DENGUE RISK

Henrik Salje[1], Kishor Paul[2], Repon Paul[2], Ziaur Rahman[2], Mohammed Shafiul Alam[2], Mahmudur Rahman[3], H. M. Al-Amin[2], James Heffelfinger[4], Emily Gurley[5]

[1]Institut Pasteur, Paris, France, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]IEDCR, Dhaka, Bangladesh, [4]World Health Organization, Geneva, Switzerland, [5]Johns Hopkins University, Baltimore, MD, United States

Nationally representative serostudies are invaluable for answering a wide range of broadly generalizable questions on population-level immunity to pathogens, historic circulation patterns, and risk factors for infection, but are rare because they are resource-intensive. Such studies are particularly needed for dengue where undetected outbreaks are common. We present the first nationally representative study of dengue in Bangladesh. We visited 70 randomly selected communities twice (in 2014 and 2015) and recruited >80 individuals of all ages per community. We collected questionnaire data on potential risk factors, collected sera that were tested for dengue IgG antibodies (PanBio), trapped and speciated mosquitoes. We used multilevel logistic regression to explore the role of individual- (e.g., age, sex, travel), household- (e.g., mosquito control) and community-level (e.g., rural/urban, *Aedes aegypti/albopictus* presence) factors on seropositivity. We used catalytic models to estimate the annual number of infections and built predictive maps of seropositivity for the country. Out of 5,866 participants, 24% had evidence of prior infection, ranging from 3% for locations in the north to >80% in urban centers of Dhaka and Chittagong. While all communities had at least one seropositive individual, 41 (59%) of locations had <20% seropositivity. Being male (adjusted odds ratio [aOR]: 1.8, 95% confidence interval [95%CI]: 1.5-2.1), recent travel (aOR: 1.3, 95%CI:1.0-1.7) and urban setting (aOR: 2.0, 95%CI:1.1-3.7) were associated with increased seropositivity. *Ae. aegypti* was found in 23 (33%) communities and its presence was significantly associated with seropositivity (aOR: 2.3, 95%CI 1.3-4.0), whereas *Ae. albopictus* presence was not (p=0.92). We estimate 2.4 million annual infections and that 34 million in the population have ever been infected. Our findings show that outside urban centers, the majority of Bangladesh remains susceptible, with the limited presence of *Ae. aegypti* a key mitigating factor for occurrence of outbreaks. Changes in climate and land use that promote its habitat could increase future outbreak risk.

919

DEVELOPMENT AND IMPLEMENTATION OF A UNIVERSAL DENGUE VIRUS SEQUENCING ASSAY FOR GENOTYPING AND GENOMIC SURVEILLANCE

Gilberto A. Santiago[1], Glenda Gonzalez-Morales[1], Leticia Franco[2], Jairo Mendez-Rico[3], Jorge L. Munoz-Jordan[1]

[1]Centers for Disease Control and Prevention, San Juan, PR, United States, [2]Pan American Health Organization, Panama City, Panama, [3]Pan American Health Organization, Washington, DC, United States

The global expansion of dengue virus (DENV) has driven the divergence of genotypes and other sub-genotypic lineages, which have been associated with epidemic potential and more severe clinical manifestations. Knowledge of virus diversity and phylogeny in the Americas is limited, largely affected by the lack of genomic surveillance and substantial underrepresentation in the public genome repositories. In order to address this deficiency, we collaborated with the Pan American Health Organization (PAHO) to develop the Dengue Genomic Surveillance Project in the Americas (ViGenDA) to facilitate the systematic study of DENV genomic diversity integrated to molecular and epidemiological surveillance. Thereupon, we developed a partial genome sequencing assay capable of sequencing directly from clinical specimens and is readily adaptable to any dengue molecular surveillance laboratory. Serotype-specific oligonucleotides were designed to detect contemporary genotypes with public health relevance. The CDC Dengue Virus E Gene Sequencing Assay is serotype-specific and targets the envelope (E) glycoprotein gene, which is amplified by a single RT-PCR protocol and sequenced with a bi-directional terminator dye Sanger method. Consensus sequence of the complete E gene is assembled with a minimum 2x coverage achieved through this assay. To determine if the assay can amplify and sequence global strains of DENV, we tested a panel of 25 DENV strains isolated from diverse global regions representing a variety of genotypes within the 4 serotypes. We obtained E gene contigs of sequence with ≥ 2x coverage from all strains except for a sylvatic isolate whose target sequence varies significantly from the rest of the contemporary strains and only partial sequence was obtained. To date, this assay has been transferred to over 14 laboratories, partners of the network of arbovirus laboratories of the Americas (RELDA) through a series of laboratory workshops. More than 4 participating laboratories currently implement this assay as part of their surveillance and efforts are underway to harmonize dengue genomic surveillance across the Americas.

ZIKA VIRUS AND TRAVEL IN THE NEWS - A MEDIA CONTENT ANALYSIS

James Herrington[1], Linda Squiers[2], Molly Lynch[2], Suzanne Dolina[2], Sarah Ray[2], Bridget Kelly[2], Mallory Turner[1], Devika Chawla[1], Sylvia Becker-Dreps[1], Lola Stamm[1], Lauren McCormack[2]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [2]RTI International, Research Triangle Park, NC, United States

The purpose of this study was to understand what information the media communicated about Zika virus (ZIKV) and travel in 2016 and 2017. We obtained a stratified, random sample of English-language, U.S. print newspaper and television news coverage about ZIKV and travel from April 5, 2016 to March 31, 2017. We developed a coding scheme to assess key messages in the news, including how and where ZIKV is transmitted, symptoms and outcomes of ZIKV, and recommended preventive behaviors. Media coverage peaked in August 2016, when the Centers for Disease Control and Prevention (CDC) issued a travel advisory for Miami, FL. Almost all news stories mentioned mosquito-borne transmission (96.8%) and most stories mentioned pregnant women as an at-risk group (89.7%). News stories mentioned sexual transmission (55.3%) or men as an at-risk group (35.3%) less frequently. News stories were more likely to talk about outcomes (78.8%) than ZIKV symptoms (40.6%). CDC was the most frequently mentioned information source (79.5%). Although the media communicated key messages about ZIKV, more nuanced messages were missing. The study offers unique insights into what information the media provided the public about the risks of ZIKV and travel.

921

USE OF MACHINE LEARNING IN SURVEILLANCE CASE IDENTIFICATION FOR THE ZIKA EMERGENCY RESPONSE

Richard Lusk[1], John Zimmerman[1], Kelley VanMaldeghem[1], Suzanna Kim[1], Nicole Roth[2], James Lavinder[1], Anna Fulton[2], Meghan Raycraft[1], Romeo Galang[3]

[1]Deloitte, Atlanta, GA, United States, [2]Eagle Medical Services, Atlanta, GA, United States, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States

Zika virus (ZIKV) infection during pregnancy is a cause of birth defects including microcephaly and other central nervous system anomalies. In 2016, CDC and public health partners established pregnancy registries to monitor health outcomes among pregnant women with ZIKV infection and their infants. During an emergency response, clinical data are collected rapidly and must be reviewed to identify cases of interest using standardized surveillance case definitions. This is a resource and time-intensive effort. Machine learning and natural language processing

methods were applied to available data from the US Zika Pregnancy and Infant Registry (USZPIR), collected from January 2016 to October 2017, to identify potential cases of interest algorithmically and to reduce the number of non-cases of interest needing review. Cases of interest are defined as pregnancies with evidence of Zika-associated birth defects. Data were collected through systems tailored for the US territories and freely associated states (territories) and for the 50 US states and District of Columbia (states). An ensemble method was developed for each data set separately based on manually determined case outcomes. The method aggregates several models including support vector machines, random forests, and gradient boosted trees to determine potential cases of interest. Across both data sets, the machine learning models exhibited high sensitivity for identifying cases of interest while proving potential time savings. Models developed for data collected from the territories would have averaged a time savings of 66% while maintaining 97% sensitivity in predicting cases of interest. Models developed for data collected from the states would have averaged a time savings of 50% while maintaining 96% sensitivity in predicting cases of interest. These models demonstrate the potential application of machine learning and natural language processing for augmented case identification and for reducing unnecessary clinical review volume during a public health emergency response.

922

IS THERE A GENETIC BASIS FOR SALIVARY GLAND INFECTION AND ESCAPE BARRIERS TO ARBOVIRAL INFECTION AND TRANSMISSION?

Irma J. Sanchez-Vargas, Kennett E. Olson, William C. Black IV

Colorado State University, Fort Collins, CO, United States

In almost all arthropod vectors of disease the salivary gland is the organ that ultimately transmits a pathogen from an infected mosquito into the vertebrate host. Salivary gland infection barriers (SGIBs) and salivary gland escape barriers (SGEBs) determine whether the saliva of a mosquito will contain sufficient numbers of pathogens to overcome the vertebrate immune system. SGIBs are manifest as the absence of detectable pathogen in the salivary glands of mosquitoes that have a disseminated infection. There are large numbers of studies that document SGIBs for bunyaviruses and flaviviruses. SGEBs on the other hand are manifest as the absence of detectable virus in the saliva of mosquitoes that have infected salivary glands (as determined by bioassay of dissected glands). In contrast to SGIBs, there are very few studies that document SGEBs in mosquitoes and those have only examined bunyaviruses. Consequently we have little understanding of whether there is a genetic basis for SGEBs or whether they are random, subject to a few or many "environmental" factors. Herein we used a half-sib analysis to examine the quantitative genetics of SGIB and SGEB for three viral species in a freshly colonized strain of *Aedes aegypti* from Mapastepec, Mexico. We wished to determine the relative contributions of genetic and environmental factors to variation and covariation in SGIB and SGEB for DENV2 (QR094), ZIKV(PRABC59) and CHIKV(R99659) . With DENV2, the narrow sense heritability (&lth2 &gt) of SGIB was 0.789 (P &lt= &gt3.35E-07) while &lth2 &gt for SGEB was 0.172 (P &lt= &g0.0443). With ZIKV, &lth2 &gt of SGIB was 0.153 (P &lt= &g 0.041632) while h^2 SGEB was 0.336 (P = 0.00024). With CHIKV, the h^2 of SGIB was 0.000 (P &lt= &g 1) while the narrow sense heritability for SGEB was 0.461 (P &lt= &g0.0005075). In infections with DENV2 there is a large genetic component associated with a SGIB but not with ZIKV or CHIKV. In ZIKV and CHIKV the SGIB &lth2 &gt was low because the salivary glands of all individuals became infected at uniformly high titers. The genetic contribution to SGEB In infections with ZIKV and CHIKV was a moderate but with DENV2 was very low.

923

DEVELOPMENT OF A POINT OF CARE METHOD FOR DETECTION OF ZIKA VIRUS BASED ON LOOP-MEDIATED ISOTHERMAL AMPLIFICATION

Oscar Escalante-Maldonado[1], Maria Paquita Garcia[1], Cesar Cabezas[1], Ronnie Gustavo Gavilan[1], Wataru Yamazaki[2]

[1]National Institute of Health, Lima, Peru, [2]University of Miyazaki, Miyazaki, Japan

The recent emergence of Zika virus disease (ZVD), a febrile viral illness, highlight the need for point-of-care testing. One of the main problems is the lack of standardized diagnostic tools that involves minimal laboratory capacity which is urgently required to facilitate early detection of ZVD. We developed a novel method based on reverse transcriptase loop-mediated isothermal amplification (RT-LAMP) to detect Zika Virus (ZikV). The ZikV RT-LAMP primers were designed based on the NS5 region using a multiple alignment of 64 ZikV complete genomes. Dried LAMP reagent was used for the reaction. Initial specificity and sensitivity assays were performed. Seven RNA templates of different arboviruses were analyzed by the RT-LAMP and only the samples positive for zika virus returned positive. Additionally, serial dilutions of one of the ZikV RNA templates we tested by RT-LAMP and real time RT-PCR (CDC-US). Comparison results showed that RT-LAMP is 1000 times more sensitive than real time RT-PCR; reveling detection limit as low as 0.0007pg. We also evaluated 250 serum samples using the RT-LAMP and the results were compared with the RT-PCR and obtained a sensitivity of 96.77, a specificity of 100, a positive predictive value of 100 and a negative predictive value of 99.2. the sensitivity, specificity, (PPV) and (NPV). Our novel ZikV RT-LAMP proved to have good performance and reliability. Currently we are running a field validation where the ZikV RT-LAMP dried reagent was proven useful because its transportation and storage do not necessarily require refrigerated or frozen conditions. Confirmation of the utility of this point-of-care testing provide a low-cost alternative for rapid diagnosis of ZVD in primary health care facilities or local hospitals with resource-limited laboratories.

924

THE ROLE OF CROSS-REACTIVE DENGUE VIRUS ANTIBODIES IN SEXUAL TRANSMISSION OF ZIKA VIRUS

Cesar A. Lopez, Alison M. Schaefer, Sam K. Lai, Helen M. Lazear

University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

In addition to being the first example of a teratogenic human arbovirus, Zika virus (ZIKV) is also the first example of an arbovirus that can be sexually transmitted. ZIKV is now co-endemic in Latin America with the closely related flavivirus, dengue virus (DENV). Since DENV is highly prevalent throughout this region, a large proportion of individuals at risk of ZIKV transmission previously have been exposed to DENV. Antibody responses between ZIKV and DENV are highly cross-reactive but do not cross-neutralize and provide minimal cross-protection from vector-borne transmission of these viruses. However, the effect of cross-reactive DENV antibodies on sexual transmission of ZIKV is unknown. IgG is secreted from systemic circulation into vaginal mucus, and is the predominant antibody in the vagina. Unlike IgG in plasma, vaginal IgG interacts with mucins, and the cumulative effect of multiple low-affinity Fc-mucin interactions can immobilize antibody-bound particles, even if those antibodies are non-neutralizing. This immobilization contributes to protection from sexual transmission of pathogens including herpes simplex virus-2 because the virus is prevented from accessing a host cell even while the particle remains infectious. We evaluated whether a similar mechanism could allow cross-reactive non-neutralizing DENV antibodies to protect against ZIKV sexual transmission. We labeled purified ZIKV virions with a fluorescent dye and measured particle mobility in vaginal mucus in the presence of cross-reactive monoclonal and polyclonal antibodies from DENV-infected individuals. We also used a mouse model of ZIKV intravaginal infection to determine whether DENV antibodies in the vagina can protect against ZIKV intravaginal challenge, and to compare the quantity and quality of

antibody responses in the vagina to those in plasma. Future studies will include determining the epitope binding and neutralization of ZIKV by IgG in vaginal mucus from DENV and ZIKV immune women in Nicaragua.

925

DETERMINING AN IMMUNOCOMPETENT, SMALL ANIMAL SEXUAL TRANSMISSION MODEL FOR ZIKA VIRUS

Megan R. MIller, Richard Bowen, Tony Schountz, Brian Foy

Colorado State University, Fort Collins, CO, United States

Zika virus (ZIKV) is a mosquito borne flavivirus that has been prevalent in Asia, parts of Africa, and Central and South America. The recent pandemic in South and North America resulted in over 1,000,000 cases. The most common symptoms of Zika virus disease are rash, arthralgia, conjunctivitis and headache, however compilations have been observed including Guillain-Barré syndrome and birth defects in infected newborns. Interestingly, ZIKV is the only known flavivirus to be able to transmit sexually. This study was undertaken to determine an immune-competent, non-primate, small animal model that would be valuable for understanding the mechanism of ZIKV sexual transmission. Previous published evidence showed that cottontail rabbits and guinea pigs seroconvert after inoculation with ZIKV, and other infection studies suggested that *Mastomys natalensis* are host for serval arboviruses. We are looking for evidence of infections in male tissues and body fluid of these three animal models; rabbits (NZW strain), guinea pigs (Hartley strain) and *Mastomys natalensis*. Groups of each species are being inoculated with ZIKV or uninfected cell culture media, and then blood, oral swab, urine and semen samples are collected and tested for ZIKV by q-RT-PCR and plaque assays. To date, we have determined that NZW rabbits are not a competent model for ZIKV sexual transmission. Additional results are pending. Once an animal model is determined we will use it to study if differences in virus tropism or disease pathology occur by different route of infections (needle inoculation, mosquito bite, and sexual transmission). By determining an immune-competent, non-primate, sexual transmission animal model for ZIKV we hope to begin addressing many unknown questions about this mode of transmission and its influence on ZIKV disease.

926

IMAGINING ZIKA: EPIDEMIOLOGY, GLOBAL HEALTH, AND UNCERTAINTY

Rebecca R. Henderson[1], Kevin Bardosh[1], Anna M. Stewart Ibarra[2]

[1]University of Florida, Gainesville, FL, United States, [2]State University of New York (SUNY) Upstate Medical University, Syracuse, NY, United States

On September 25, 2017, the headline of the Tampa Bay Times wondered, "What Ever Happened to Zika?". In coming to understand "what happened to Zika", it is crucial to first understand how our ideas about Zika were formed. This paper offers a first answer this question through a reexamination of the evidence that formed the basis of scientific predictions, retracing the ways that a picture of the virus emerged based on limited knowledge, best guesses, and public anxiety. In so doing, it takes a close look at how inconsistencies in Zika predictions emerged from a series of gaps in knowledge about fundamental features of the disease. It demonstrates how representations of the epidemic throughout the sciences were mired in uncertainty at every level, and that these uncertainties allowed scholarship on Zika to be partially guided by social and cultural forces. This paper further suggests that this process had concrete consequences for policy. In understanding how scientists "created" a picture of Zika even as they attempted to locate it, this paper further examines the ramifications for arboviruses and for tracking future emerging epidemics. It suggests that in the context of fundamental uncertainty about how a new disease works, scientists must learn to depart from the norms of scientific publication in order to make especially explicit the degree to which their findings are certain. Further, uncertainty is particularly underrepresented in attempts to communicate findings to those interested in creating policy. It is crucially important to critically examine methods of communication of uncertainty, as well as the potential consequences of action guided by uncertain evidence. However, this paper further proposes that by reexamining the assumptions behind epidemiology, there is an opportunity to creatively redesign scientific processes to better depict and predict disease in ways that will be more useful to those engaged in disease control.

STRUCTURAL PROTEINS PRME DICTATE SEXUAL TRANSMISSION POTENTIAL OF ZIKV IN AN IMMUNOCOMPETENT MOUSE MODEL

Erin M. McDonald[1], Nisha K. Duggal[2], Jana M. Ritter[3], Aaron C. Brault[1]

[1]Division of Vector-Borne Diseases, Centers for Disease Control and Prevention, Fort Collins, CO, United States, [2]Department of Biomedical Sciences & Pathobiology, Virginia-Maryland College of Veterinary Medicine, Blacksburg, VA, United States, [3]Division of High-Consequence Pathogens and Pathology, Centers for Disease Control and Prevention, Atlanta, GA, United States

The sexual transmission potential of African genotype Zika virus (ZIKV) strains cannot be studied in models deficient of IFN response [type I/II receptor knockout (AG129) mice] due to rapid and high mortality rates after inoculation with African genotype viruses. To overcome this challenge, a longitudinal ZIKV study was carried out in immunocompetent C57bl/6 mice treated with a monoclonal antibody against type I IFN receptor. In C57bl/6 mice, following transient knockdown of type I IFN signaling, delayed and/or reduced mortality was observed with all ZIKV strains compared to similar inoculations of AG129 mice. The African and Asian genotype ZIKVs, with the exception of a 2015 Asian genotype isolate (PRVABC59), demonstrated similar sexual transmission potential in this C57bl/6 model. Similar proportions of ejaculates from C57bl/6 mice inoculated with either Asian or African genotype ZIKV strains contained both viral RNA and infectious virus; however, none of the ejaculates from mice inoculated with PRVABC59 virus contained virus. To determine if viral structural elements mediate sexual transmission potential differences observed between PRVABC59 and African genotype ZIKVs, the prME genes from MR766 (African genotype) were cloned into a cDNA clone of PRVABC59. Mice inoculated with a prME chimeric virus generated higher viral titers in the epididymis during acute infection compared to PRVABC59-inoculated mice. Furthermore, ejaculates from mice inoculated with the prME chimeric virus contained infectious virus at titers similar to ejaculates collected from mice inoculated with MR766 virus. Overall, all ZIKVs tested, except for a strain from the current outbreak, had the potential for sexual transmission in an immunocompetent mouse model. The potential significance of type II IFN for modulation of sexual transmissibility of ZIKV is evidenced by the lack of sexual transmission potential of the PRVABC59 Asian genotype virus in transient type I knockdown mice as opposed to sexual transmission in type I/II IFN receptor deficient mice.

HUMAN TESTICULAR ORGANOID MODEL AS AN *IN VITRO* SYSTEM TO INVESTIGATE ZIKA VIRUS PATHOGENESIS

Daniel P. Strange[1], Nima P. Zarandi[2], Goral Trivedi[1], Anthony Atala[3], Colin E. Bishop[2], Hooman Sadri-Ardekani[3], Saguna Verma[1]

[1]Department of Tropical Medicine, Medical Microbiology, and Pharmacology, John A. Burns School of Medicine, University of Hawaii at Manoa, Honolulu, HI, United States, [2]Wake Forest Institute for Regenerative Medicine (WFIRM), Salem, NC, United States, [3]Wake Forest Institute for Regenerative Medicine (WFIRM); Department of Urology, Wake Forest School of Medicine, Salem, NC, United States

Zika virus (ZIKV) is an arbovirus belonging to the *Flavivirus* genus of the *Flaviviridae* family. The 2015-16 ZIKV epidemic in South America resulted

in more than 1.5 million symptomatic cases. Traditionally associated with mild fever, the recent outbreak presented new severe features of ZIKV disease, including neonatal microcephaly and Guillain-Barre syndrome in adults. Further, sexual transmission of ZIKV emerged as a cause of disease spread to non-endemic regions, a unique finding not reported for other flaviviruses. ZIKV has been detected in semen for up to 188 days after symptoms onset and is shown to potentially affect fertility, indicating ZIKV establishes persistence in the testes. Our recent study demonstrated that ZIKV could efficiently infect human Sertoli cells (SC), an important cell type that contributes to the immune privilege environment of seminiferous tubules. However, due to lack of relevant animal models to study ZIKV pathogenesis and apparent limitations of monolayer cultures, an *in vitro* system that incorporates multiple human testicular cell types to partially recapitulate testis function is considered ideal to investigate pathogenic features of ZIKV infection in the human testes. Our collaborators recently developed a human testicular organoid (hTO) model, consisting of multiple testicular cell types, that produces testosterone continuously and partially supports early stages of spermatogenesis. Our objective here was to evaluate the hTO model as an *in vitro* system to study ZIKV pathogenesis. hTOs were infected with an epidemic ZIKV strain and then subsequently assessed for virus replication, viability, and function post-infection. We found that hTOs supported productive ZIKV replication, which resulted in reduced hTO survival and function. Our results also demonstrated induction of key antiviral genes *IFNB* and *IFIT1* and the pro-inflammatory cytokine gene *IL6* following ZIKV infection. Collectively, our results indicate that the hTO model can be used as a relevant *in vitro* system to study ZIKV infection of human testes, including cellular tropism, immune response, and potential effects on spermatogenesis.

929

LOCAL AND REGIONAL DYNAMICS OF ZIKA VIRUS TRANSMISSION IN THE AMERICAS: THE ROLE OF MISMATCHED SPATIAL HETEROGENEITY

Sean Moore[1], James Soda[1], Benoit Raybaud[2], Edward Wenger[2], Philip Welkhoff[3], Alex Perkins[1]

[1]University of Notre Dame, Notre Dame, IN, United States, [2]Institute for Disease Modeling, Bellevue, WA, United States, [3]Bill & Melinda Gates Foundation, Seattle, WA, United States

Models of transmission dynamics are routinely fit to spatially-aggregated epidemiological time series even though transmission is typically heterogeneous at fine spatial scales. For example, numerous models have used national-level time series of Zika cases for forecasting and inferential purposes in the Americas since Zika virus was first reported in Brazil in 2015. Analyses of nationally aggregated time series data might bias model inference or prediction, leading to poorly targeted public health interventions. To examine whether modeling transmission dynamics below the scale of spatially-aggregated case reports could improve model fit and capture spatial heterogeneity in disease incidence, we fit an individual-based transmission model to case data from several Central and South American countries as follows: (1) single-patch national models fit to national data; (2) multi-patch national models fit to national data, where patches represent 1st-level administrative units; and (3) multi-patch sub-national models fit to sub-national data, where patches represent 2nd-level units. Model consistency with observed dynamics improved with increasing model granularity. For the majority of countries (7 of 10), the multi-patch national model better captured national-level temporal patterns than did the single-patch national model, reducing the weekly mean absolute error (MAE) (e.g., MAEs for El Salvador and Costa Rica were reduced by 19.9% and 11.4%, respectively). Furthermore, sub-national predictions of incidence benefitted significantly from incorporating information about the timing of introduction at the sub-national level into the fitting process. For example, the correlation between modeled and reported province-level incidence in Ecuador was 0.48 (95% CI: -0.02-0.93), significantly higher than a null model assuming uniform incidence across provinces (Wilcox signed rank test; $p<0.01$). Overall, more granular models performed better by better matching human populations with locally relevant risk, suggesting that these models can be used to estimate heterogeneity in incidence at policy-relevant spatial scales.

LONG TERM PERSISTENCE OF ZIKA VIRUS IN RHESUS MACAQUE TISSUES

Michael K. McCracken, Mark A. Sanborn, Bridget S. Lewis, J. Robert Putnak, Richard G. Jarman, Gregory D. Gromowski, Irina Maljkovic Berry, Wiriya Rutvisuttinunt

Walter Reed Army Institute of Research, Silver Spring, MD, United States

Previous *in vitro* studies have demonstrated cross-reactivity of antibodies derived from dengue virus (DENV) and yellow fever virus (YFV) infections with Zika virus (ZIKV), as well as antibody-mediated enhancement of infection in cell culture. We evaluated the impact of prior heterotypic flavivirus infection on ZIKV titers in biofluids and tissues of rhesus macaques at multiple time points post exposure. Animals previously infected (≥420 days) with DENV2, DENV4, or yellow fever virus ("flavivirus-immune") were compared to flavivirus-naïve animals following infection with a Brazilian ZIKV strain. Both the flavivirus-immune and flavivirus-naïve groups exhibited similar ZIKV titers across most tested tissues through day 10 post exposure. Long after the biofluids no longer presented detectable ZIKV in all animals, the spleen and the draining lymph node nearest the inoculation site were consistently positive through day 56 in both groups, and positive in only the flavivirus-naïve group on day 112 post exposure. Overall, the results indicate that prior infection with DENV or YFV did not meaningfully alter ZIKV titers or tissue distribution during the viremic period, and suggest the potential for greater tissue persistence in the flavivirus-naïve animals at later time points.

931

DURATION OF DETECTION OF ANTI-ZIKA VIRUS IGM ANTIBODY IN A PROSPECTIVE COHORT STUDY

Matthew J. Lozier[1], Eli Rosenberg[2], Kate Doyle[3], Jorge L. Muñoz-Jordan[1], Emma Little[4], Liore Klein[4], Manuela Beltran[1], Laura Adams[1], Luisa I. Alvarado[5], Gabriela Paz-Bailey[1], Tyler M. Sharp[1]

[1]Centers for Disease Control and Prevention, San Juan, Puerto Rico, [2]University at Albany-SUNY, Albany, NY, United States, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Oak Ridge Institute for Science and Education, Oak Ridge, TN, United States, [5]Ponce Health Sciences University, Ponce, Puerto Rico

Understanding the duration of detection of anti-Zika virus (ZIKV) IgM antibody is necessary to inform diagnostic testing algorithms. CDC recommends testing serum specimens collected up to 12 weeks after symptom onset or ZIKV exposure for anti-ZIKV IgM. Using data from a cohort of patients with ZIKV disease in Puerto Rico confirmed by RT-PCR, we estimated the time to first detection and loss of detection of anti-ZIKV IgM antibody. Index patients were recruited following detection of ZIKV RNA in serum or urine specimens. Index-patients' household contacts were also tested, and if positive by RT-PCR were invited to join the cohort. Follow-up visits occurred every week for four weeks and at 2, 4 and 6 months post-enrollment. Serum collected at each visit was tested by anti-ZIKV IgM antibody capture enzyme-linked immunosorbent assay (MAC ELISA). Data were used to determine appearance and loss of anti-ZIKV IgM detection as a function of days post-symptom onset (DPO). We used repeated-measures logistic regression to model the proportion of specimens with detectable IgM over time, yielding the estimated times at which 50% and 25% of specimens were still IgM-positive. Of 279 symptomatic cohort participants, 135 (48.4%) were female, including nine pregnant women, and median age was 36 years (range: 9 months–83 years). Anti-ZIKV IgM antibody was detected in 271 (97.1%) participants. Of 22 specimens collected from 0–3 DPO, anti-ZIKV IgM was detected in six (27.3%). About 80% (61/77) of the specimens collected from 4–7 DPO had detectable ZIKV IgM. The estimated time when 50% and 25%

of participants still had detectable anti-ZIKV IgM was 97 days (95%CI: 91, 103) and 125 days (95%CI: 118, 134), respectively. Participants aged <18 years had a significantly shorter time to 50% detection than other participants (p=0.03). No significant differences were observed by sex. These data suggest nearly all symptomatic ZIKV-infected individuals develop anti-ZIKV IgM antibody, and half will still have detectable IgM antibodies about three months after symptom onset. These observed estimates are consistent with current CDC testing recommendations.

932

EFFECTS OF AGE, BLOOD MEAL ACQUISITION, AND MORTALITY ON THE TRANSMISSION POTENTIAL OF ZIKA VIRUS

E. Handly Mayton, Rebecca C. Christofferson

Louisiana State University School of Veterinary Medicine, Baton Rouge, LA, United States

Zika virus (ZIKV) is a mosquito-borne flavivirus currently circulating in South America. A widespread outbreak of the virus was first detected in Brazil in 2015, and has quickly spread throughout South and Central America. Unlike previous outbreaks, cases of ZIKV from the current outbreak have been linked to severe symptoms, including microcephaly in newborns and neurological complications in adults. There are currently no antiviral treatments or vaccines available, and prevention relies solely on vector control. Understanding the factors that affect viral transmission from mosquito to human is critical when designing vector control strategies. Specifically, we investigated the interactions of mosquito age, order of infectious blood meal, and mosquito mortality in order to assess the transmission potential of ZIKV. Cartons of *Aedes aegypti* were subjected to three different treatments to assess average time to viral dissemination. These treatments include a single ZIKV blood meal 3-5 days post-emergence, a single ZIKV blood meal 10-12 days post-emergence, and a non-infectious blood meal 3-5 days post-emergence, followed by a ZIKV blood meal 10-12 days post-emergence. Sampling was performed at multiple days post-exposure. Using qRT-PCR, abdomens and legs were tested separately for infection and dissemination, respectively. To assess average time to death, the same treatments were used, and dead mosquitoes were collected and counted daily for 23 days. We found no significant difference in average time to dissemination between the three treatments; however, the average time to death was significantly different among the three treatments. Our results suggest that interactions between age, order of infectious blood meal, and mortality change the transmission potential of ZIKV in *Aedes aegypti.* Furthermore, these observations provide insight into potential vector control methods for ZIKV-exposed mosquitoes.

933

SAFETY AND IMMUNOGENICITY OF MEASLES, MUMPS, AND RUBELLA VACCINE [PRIORIX, GLAXOSMITHKLINE BIOLOGICALS] CO-ADMINISTERED WITH LIVE ATTENUATED SA 14-14-2 JAPANESE ENCEPHALITIS VACCINE [CD.JEVAX, CHENGDU INSTITUTE OF BIOLOGICAL PRODUCTS]

Maria Rosario Capeding[1], Edison Alberto[1], **Jodi Feser**[2], Jessica Mooney[2], Yuxiao Tang[2], Judy A. Beeler[3], Damon W. Ellison[4], Lei Zhang[5], G. William Letson[2], Anthony A. Marfin[2]

Japanese encephalitis (JE) virus is the leading cause of viral encephalitis across temperate and tropical zones of Asia. The live attenuated SA 14-14-2 JE vaccine (CD-JEV) is one of several vaccines prequalified by the World Health Organization to prevent JE. When incorporating a new vaccine into a country's Expanded Programme on Immunization, it is important to show that the new vaccine can be administered concurrently with other routine pediatric vaccines without impairing the immune response or safety profile of the coadministered vaccines. This Phase 4 open-label study evaluated the safety and immunogenicity of measles, mumps, and rubella (MMR) vaccine co-administered with CD-JEV. The study randomized 628 healthy Filipino children aged between 9 and 10 months to receive MMR and CD-JEV concurrently or separately. JE immunogenicity was assessed 28 days after CD-JEV vaccination using plaque reduction neutralization test (PRNT). MMR immunogenicity was assessed 56 days after MMR vaccination using a measles PRNT, anti-mumps immunoglobulin G (IgG) enzyme-linked immunosorbent assay (ELISA), and anti-rubella IgG ELISA, respectively. Safety was assessed through observation for reactions immediately following immunization, solicitation of systemic adverse reactions occurring within 14 days of vaccination, and follow-up of serious adverse events during 7 to 8 months of study participation. During the study, no vaccine-associated encephalitis cases or serious adverse events were reported in either group, and concurrent immunization with CD-JEV and MMR vaccines was not associated with any unusual safety signals when compared with sequential immunization. Complete serologic results will be available by June 2018.

934

DETECTION AND MOLECULAR CHARACTERIZATION OF ZIKA VIRUS IN SPECIMENS COLLECTED DURING 1998 TO 2017 FROM THAILAND

Damon W. Ellision[1], Chonticha Klungthong[1], Piyawan Chinnawirotpisan[1], Wudtichai Manasatienkij[1], Yongyuth Poolpanichupatam[1], **Kittinun Hussem**[1], Butsaya Thaisomboonsuk[1], Jindarat Lohachanakul[1], Ananda Nisalak[1], Darunee Buddhari[1], Benjawan Khuntirat[1], Piyarat Suntarattiwong[2], Veerachai Watanaveeradej[3], Detchvijitr Suwanpakdee[4], Sriluck Simasathien[4], Thippawan Chuenchitra[5], Sarunyou Chusri[6], Rome Buathong[7], Alden L Weg[1], Katie Anderson[1], Louis R. Macareo[1]

[1]Department of Virology, United States Army Medical Directorate, Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [2]Department of Pediatrics, Queen Sirikit National Institute of Child Health, Bangkok, Thailand, [3]Department of Microbiology, Phramongkutklao College of Medicine, Bangkok, Thailand, [4]Department of Pediatrics, Phramongkutklao Hospital, Bangkok, Thailand, [5]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [6]Department of Internal Medicine, Faculty of Medicine, Prince of Songkla University, Songkla, Thailand, [7]Bureau of Epidemiology, Department of Disease Control, Ministry of Public Health, Nonthaburi, Thailand

The Department of Virology, AFRIMS has conducted surveillance for mosquito-borne viral pathogens for several years in Thailand. Following the WHO's declaration of Zika virus (ZIKV) as a public health emergency in 2016, AFRIMS added ZIKV testing to our current prospective dengue surveillance studies and outbreak investigations, and also began retrospectively testing specimens collected to assess for the extent of ZIKV circulation in Thailand. Since March 2016, ZIKV real-time RT-PCR has been performed on a total of 3,634 acute specimens collected in Thailand from 1998 to 2017. The specimens tested include whole blood, serum, plasma, and urine. Seventy percent of the specimens (2,528/3,634) had previously tested negative for dengue virus RT-PCR. The overall ZIKV positivity rate of detection by real-time RT-PCR in this study was 1.7% of total specimens tested (61/3,634). The positive detection rate by specimen type was 12% for whole blood (19/164), 0.5% for serum (14/2,796), 0% for plasma (0/62) and 4.6% for urine (28/612). ZIKV was detected in the specimens collected from five years including 2011, 2013, 2014, 2015, and 2017. We were able to isolate a total of 9 ZIKV viruses from RT-PCR positive specimens including 8 new isolates reported here and 1 previously reported isolate from 2014. Complete genome sequences of the 8 new isolates, obtained from specimens collected from the five years, were generated and analyzed with other sequences from GenBank. Phylogenetic analysis showed that all of the isolates were clustered close

to and belonged to the Asian genotype. The single mutation in the prM protein that has been suggested to contribute to fetal microcephaly was not found in our ZIKV sequences. The sequences of binding sites for the primers and probes used in ZIKV real-time RT-PCR were also observed in order to monitor mutations that might impact to the sensitivity of the used assay. Mismatch at five positions were found. Continued investigation and analysis of the molecular characteristics of ZIKV circulating in Thailand will provide more accurate and up-to-date information about ZIKV transmission and its clinical impact on global public health.

935

LABORATORY ANALYSIS OF ARBOVIRUS SURVEILLANCE IN SOUTHERN THAILAND FROM 2012-2015

Butsaya K. Thaisomboonsuk[1], Sarunyou Chusri[2], Damon W. Ellison[1], Chonticha Klungthong[1], Winai Kaneechit[1], Piyawan Chinnawirotpisan[1], Yongyuth Poolpanichupatam[1], Prinyada Rodpradit[1], Taweewun Hunsawong[1], Prapapun Ong-ajchaowlerd[1], Rungarun Suthangkornkul[1], Jindarat Lohachanakul[1], Thongchai Khiankaew[1], Chutithorn Tawilert[1], Kanittha Sirikajornpan[1], Ananda Nisalak[1], Richard G. Jarman[3], In-Kyu Yoon[4], Stefan Fernandez[5], Kathryn B. Anderson[1], Alden L. Weg[1], Louis R. Macareo[1]

[1]Department of Virology, Armed Forces Research Institute of Medical Sciences (AFRIMS), Bangkok, Thailand, [2]Department of Internal Medicine, Faculty of Medicine, Prince of Songkla University (PSU), Hat Yai, Thailand, [3]Department of Virus Diseases, Walter Reed Army Institute of Research (WRAIR), Bethesda, MD, United States, [4]International Vaccine Institute (IVI), Seoul, Republic of Korea, [5]The United States Army Medical Materiel Development Activity (USAMMDA), Fort Detrick, MD, United States

Since 2012, the Armed Forces Research Institute of Medical Sciences (AFRIMS), in collaboration with Prince of Songkla University (PSU) has conducted arbovirus surveillance in Southern Thailand in an effort to identify and characterize dengue (DENV), chikungunya virus (CHIKV), Japanese encephalitis Virus (JEV), and Zika virus (ZIKV) circulation. Patients presenting with undifferentiated febrile illnesses and dengue-like symptoms were enrolled at PSU Hospital and the surrounding local hospitals. Acute and convalescent samples were collected for flavivirus nucleic acid testing and when possible a 14 day convalescent sample was taken. Semi-nested DENV/JEV/CHIKV RT-PCR and Zika real time RT-PCR conducted on acute samples identified 219 DENV (219/970), 3 CHIKV (3/679), 0 JEV (0/755) and 3 ZIKV (3/337) positive specimens. Serological testing on acute and convalescent samples included DENV/JEV EIA and Hemagglutination Inhibition (HAI) for DENV and CHIKV. DENV HAI seroconversion in DENV PCR positive (211 acute and 202 convalescent) and DENV PCR negative (696 acute and 676 convalescent) ranged from 58-78% and 58-81%, between 2012-2015 and both peaked at 78% and 81% in year 2013, respectively. Both DENV PCR and HAI revealed that DENV was highly endemic in Southern Thailand. CHIKV HAI seroconversion in DENV PCR positive samples was 42%, 35%, 23%, and 24% in 2012, 2013, 2014, and 2015 whereas in the DENV PCR negative group, rates were 36%, 30%, 23%, and 19% in years 2012, 2013, 2014, and 2015, respectively. A downward trend of CHIKV HAI seroconversion is seen in later years following the CHIKV outbreak in 2006-2008 but CHIKV appears to still be circulating in the area as asymptomatic cases. Plaque Reduction Neutralization Titers confirmed all 105 pairs of CHIKV HAI seroconversion. Our data showed that HAI seroconversion is useful tool to predict the endemicity of DENV and CHIKV in both DENV and CHIKV PCR positive and negative patients. This data will help us to understand arbovirus transmission and disease burden in a population living in rural and urban areas of Southern Thailand.

936

A RETROSPECTIVE STUDY USING A SEROSURVEY TO DETECT ZIKA VIRUS IN MOMBASA, KENYA

Elizabeth A. Hunsperger[1], Dennis Odhiambo[2], Albina Makio[2], Moshe Alando[2], Melvin Ochieng[2], Victor Omballa[2], Godfrey Bigogo[2], Peninah Munyua[1], Marc-Alain Widdowson[1]

[1]Centers for Disease Control and Prevention, Nairobi, Kenya, [2]KEMRI, Nairobi, Kenya

Zika virus (ZIKV) has not been confirmed in Kenya and WHO classifies Kenya as having a competent vector but no past or current documented infection. Previous ZIKV serology studies demonstrated evidence of ZIKV in Kenya using outdated immunoassays with limited specificity. We used specimens collected from a dengue seroincidence study to retrospectively test for the recent presence of ZIKV in Kenya. The dengue seroincidence study was conducted amidst a dengue outbreak to determine the incidence of dengue amongst residents of Tudor Mombasa, Kenya from May 3 to May 11, 2013 where 1500 residents from 986 randomly selected households consented to participate in the study. A questionnaire was administered to each household and a venous blood specimen was collected and tested for DENV by real-time reverse transcription polymerase chain reaction (rRT-PCR) and anti-DENV IgM. From these specimens, there were 746 determined to be DENV negative with sufficient volume to test for ZIKV by rRT-PCR, and anti-ZIKV IgM. To confirm the specificity of the results from the anti-ZIKV IgM antibody capture enzyme linked immunosorbent assay (MAC-ELISA), all positive (positive to negative ratio (P/N) ≥3) and equivocal (P/N=2-2.99) specimens are being tested with the 90% plaque reduction neutralization test (PRNT90) for ZIKV and DENV. From the 746 specimens tested to date, none were ZIKV rRT-PCR positive, 35 (4.7%) were anti-ZIKV IgM positive and 23 (3.1%) anti-ZIKV IgM equivocal. The PRNT testing is in progress however from the four specimens that were tested by PRNT, two were confirmed as a ZIKV cases, defined as ZIKV PRNT90, positive with a 4 fold higher titer for ZIKV compared to DENV. This is the first study that confirms that ZIKV infections occur in Kenya. The results suggest that similar to DENV, ZIKV may be endemic in the coastal region of Kenya and should be included in the differential diagnosis especially amongst pregnant women.

937

SEROPREVALENCE, RISK FACTOR, AND SPATIAL ANALYSES OF ZIKA VIRUS INFECTION AFTER THE 2016 EPIDEMIC IN MANAGUA, NICARAGUA

Fausto Bustos[1], José Victor Zambrana[2], Raquel Burger-Calderon[1], Damaris Collado[2], Nery Sanchez[2], Sergio Ojeda[2], Jairo C. Monterrey[2], Miguel Plazaola[2], Brenda Lopez[2], Sonia Arguello[2], Douglas Elizondo[2], William Avliés[2], Josefina Coloma[1], Guillermina Kuan[3], Angel Balmaseda[4], Aubree Gordon[5], Eva Harris[1]

[1]Division of Infectious Diseases & Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, [2]Sustainable Sciences Institute, Managua, Nicaragua, [3]Centro de Salud Sócrates Flores Vivas, Ministry of Health, Managua, Nicaragua, [4]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministry of Health, Managua, Nicaragua, [5]Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, MI, United States

In 2015, a Zika epidemic in Brazil began spreading throughout the Americas. Zika virus (ZIKV) entered Managua, Nicaragua, in January 2016 and caused an epidemic that peaked in July-September 2016. ZIKV seropositivity was estimated among participants of pediatric (n=3,740) and household (n=2,147) cohort studies, including an adult-only subset from the household cohort (n=1,074), in Managua. Seropositivity was based on a highly sensitive and specific assay, the Zika NS1 blockade-of-binding ELISA, which can be used in dengue-endemic populations. Overall seropositivity for the pediatric (ages 2-14), household (ages 2-80) and adult (ages 15-80) cohorts were 36%, 46%, and 56%, respectively. Trend, risk factor, and contour mapping analyses demonstrated that ZIKV

seroprevalence increased non-linearly with age and that body surface area was statistically associated with increasing seroprevalence in children. Seropositivity to anti-ZIKV antibodies was higher in females than in males across almost all ages, with adjusted prevalence ratios in children and adults of 1.11 (95% CI: 1.02-1.21) and 1.14 (95% CI: 1.01-1.28), respectively. No household-level risk factors were statistically significant in multivariate analyses. A spatial analysis revealed a 10-15% difference in the risk of ZIKV infections across our 3km-wide study site, suggesting that ZIKV infection risk varies at small spatial scales. To our knowledge, this is the largest ZIKV seroprevalence study reported in the Americas, and the first in Central America and in children. It reveals a high level of immunity against ZIKV in Managua as a result of the 2016 epidemic, making a second large Zika epidemic unlikely in the near future.

938

CHANGES IN BEHAVIORS ASSOCIATED WITH TRANSMISSION AMONG A COHORT OF ZIKA VIRUS INFECTED PARTICIPANTS IN PUERTO RICO

Eli Rosenberg[1], Kate Doyle[2], Laura Adams[2], Jorge Munoz[2], Liore Klein[3], Matthew Lozier[2], Tyler M. Sharp[2], Gabriela Paz-Bailey[2]

[1]University at Albany School of Public Health, Rensselaer, NY, United States, [2]Centers for Disease Control and Prevention, San Juan, PR, United States, [3]Oak Ridge Institute for Science and Education, San Juan, PR, United States

Little is known about behaviors associated with Zika virus (ZIKV) infection and transmission to either mosquitos or humans after infection, including how they may change after diagnosis with ZIKV disease. We evaluated changes in repellent use and sexual activity using data from the Zika virus Persistence (ZiPer) cohort study in Puerto Rico that began in May 2016. After presentation to healthcare facilities, ZIKV RNA-positive patients were offered study participation, including a questionnaire and testing to detect: a) ZIKV RNA in serum, urine, saliva, and vaginal fluid or semen; and b) anti-ZIKV IgM antibody in serum. All study participants were educated at enrollment about routes of ZIKV transmission, and the risks due to mosquitos and unprotected sexual contact. Questionnaires and specimens were collected weekly for the first month and at 2, 4, and 6 months. Among ZIKV RNA-positive participants, we used x^2 tests to assess changes in the percentage of participants reporting repellent use in the past 30 days, sexual activity and condom use in the past 7 days, by day post-illness onset (DPO). Among 295 RNA-positive participants, 63% reported repellent use at enrollment. In prospectively followed symptomatic participants, repellent use was 33% at 0-7 days DPO, 69% at 8-14 DPO, and 51% by ≥125 DPO. Of 226 adults, at enrollment 52% were sexually active, of whom 19% reported condom use. Sexual activity was 71% at 0-14 DPO and 50% at ≥125 DPO. Condom use among sexually-active participants was low and peaked at 34% at 46-60 DPO. Of 96 men with semen specimens, 62% were sexually active and of them 19% reported condom use at baseline. During follow-up visits, 55% were sexually active and 44% of these periods involved condom use. Between men with and without detectable RNA in semen, differences in sexual activity trends and condom use were not significant. In summary, although reported repellent use was higher after symptom onset, it declined over time. Condom use overall frequencies were low, including among men with ZIKV RNA in semen, illustrating the risk of sexual transmission. Counselling of patients with ZIKV disease should emphasize protective behaviors.

939

NEUROLOGICAL ASSESSMENT OF CHILDREN BORN TO PREGNANT WOMEN RETURNING FROM ZIKA AFFECTED AREAS: RESULTS FROM SURVEILLANCE IN A NON-ENDEMIC AREA

Elena Marbán-Castro[1], Dolors Salvia[2], Anna Goncé[2], Carolina Esteve[2], Miguel J. Martínez[1], Izaskun Alejo-Cancho[3], Marta López[2], Laura García[2], Laura Salazar[2], Marina Fuente-Moreno[1], Aina Casellas[1], Claudia Fortuny[2], Clara Menéndez[1], Azucena Bardají[1], Victoria Fumadó[1]

[1]ISGlobal, Hospital Clínic - Universidad de Barcelona. Barcelona, Spain, Barcelona, Spain, [2]Department of Maternal-Fetal Medicine, BCNatal – Barcelona Center of Maternal-Fetal and Neonatal Medicine, Barcelona, Spain, [3]Department of Clinical Microbiology, Hospital Clínic, Barcelona, Spain, Barcelona, Spain

Zika virus (ZIKV) epidemic has dramatically impacted the health of mothers and infants in affected areas. Research on ZIKV has focused on the characterization of the congenital ZIKV syndrome and the severe clinical manifestations of affected children. The long-term consequences of ZIKV infection in pregnancy on children health remain unclear. We aimed to assess the physical, neurological and psychomotor development of children born to pregnant women returning from ZIKV affected areas with a possible ZIKV infection (probable or confirmed). Active surveillance of pregnant travellers, potentially exposed to ZIKV was established at the Hospital Clínic of Barcelona, Spain, that included follow up of their children until 18 months of age. Follow up consisted of ZIKV screening at birth, weight, length, head circumference measurements, neuroimaging, ocular, hearing and psychomotor assessment, as well as the Bayley Scale for development at 18 months of age. All variables were collected using standardized questionnaires. Here, we describe a cohort of 43 children born to pregnant women with probable or confirmed ZIKV infection. All children tested negative for ZIKV at birth by PCR. Serological analysis revealed placental transfer of ZIKV maternal IgG antibodies. No growth retardation or delay in the psychomotor development was found among study children during follow up. Cerebral ultrasound did not reveal major pathological findings, however two children were found with choroid plexus cysts and with cerebral ventricular asymmetry, respectively, as a variant of normality. In addition, a study infant was diagnosed with a non-affiliated hepatitis at two months of age. Data from follow up of healthy children exposed to ZIKV in uterus is scarce, almost inexistent. Prospective studies to comprehend the neurological impact of ZIKV in these children in the long-term and its clinical and developmental consequences are crucial.

CHARACTERIZING THE IMMUNE RESPONSE TO ZIKA VIRUS USING EPITOPE MAPPING, REPORTER VIRUS PARTICLES, AND ANTI-ZIKV ANTIBODIES

Edgar Davidson[1], Chuck Whitbeck[1], Anu Thomas[1], Aubrey Bryan[1], Tabb Sullivan[1], Lewis J. Stafford[1], Gopal Sapparapu[2], James Crowe Jr.[2], Benjamin J. Doranz[1]

[1]Integral Molecular, Inc., Philadelphia, PA, United States, [2]Vanderbilt University, Nashville, TN, United States

We have characterized the immune response to ZIKV infection and vaccines by epitope mapping over 50 anti-ZIKV MAbs at amino acid-resolution, using a comprehensive ZIKV prM/E library of 672 single alanine mutants expressed in human cells. A published study described epitopes of MAbs isolated from a Brazilian patient, including a highly neutralizing MAb protective in animal models of ZIKV fetal disease. The epitope location suggested that the MAb acts by binding across adjacent protein E dimers, preventing the rearrangements necessary for ZIKV infectivity. The epitope maps obtained also reveal which epitopes are specific for ZIKV or are common to DENV, information that can be used to create better vaccines and therapeutics. We have also identified mutations that

increased ZIKV RVP budding, and which may be applicable to the design and production of anti-ZIKV vaccines, by screening each individual ZIKV library prM/E variant for ZIKV particle budding and infectivity. To provide critical reagents, we have isolated anti-ZIKV MAbs for ZIKV-specific immunodetection, diagnostic applications, and ZIKV neutralization studies. MAbs were isolated after immunization with DNA and sub-viral particles, and phage library panning with ZIKV reporter virus particles (RVPs) that we have developed, capable of one round of infectivity with luminescent or fluorescent readout. We isolated 48 conformational MAbs specific to prM/E from ZIKV, but not DENV, including a MAb that potently neutralized ZIKV RVPs (IC_{50} 45 ng/ml) and for which mapping identified a quaternary epitope spanning adjacent E proteins. We have also used ZIKV RVPs to identify new cellular receptors and attachment factors that enable ZIKV entry. ZIKV RVPs were tested on our Membrane Proteome Array (MPA), comprising 5,300 unique human membrane proteins individually expressed in live human cells. Known receptors and attachment factors were identified (validating the approach), as well as a number of membrane proteins not previously known to enable ZIKV entry. These newly identified proteins help explain viral tropism and pathogenesis, and may be useful as therapeutic targets.

941

CHARACTERIZATION OF POPULATION EXPOSURE (SEROPREVALENCE) TO ARBOVIRUSES AFTER RECENT OUTBREAKS IN COLOMBIA: DENGUE, CHIKUNGUNYA AND ZIKA

Pierre Nouvellet[1], **Zulma M. Cucunubá**[1], Isabel Rodríguez-Barraquer[2], Jessica Vanhomwegen[3], Maria-Consuelo Montoya[4], Andrea Trujillo Correa[5], Erwin Camacho Burgos[6], Maria I. Estupiñán[7], Anyela Lozano[8], Margarita Gelves[8], Mauricio Herrera[9], Jean-Claude Manuguerra[3], Maria-Gloria Basañez[1], Christl A. Donnely[1], Jorge Osorio[10], Luis A. Villar[8], Neil M. Ferguson[1]

[1]Imperial College London, London, United Kingdom, [2]University of California, San Francisco (UCSF), San Francisco, CA, United States, [3]Institute Paster, Paris, France, [4]Universidad Industrial de Santander, Pidecuesta, Colombia, [5]Universidad de Antioquia, Medellín, Colombia, [6]Imperial College London, Universidad de Sucre, Colombia, [7]Universidad Industrial de Santander, Piedecusta, Colombia, [8]Universidad Industrial de Santander, Piedecuesta, Colombia, [9]Universidad Autónoma de Bucaramanga, Bucaramanga, Colombia, [10]University of Wisconsin, Madison, WI, United States

The 2015-16 Zika (ZIKV) epidemics in Latin America took the world by surprise, much as did the chikungunya (CHIK) epidemics in 2013-14. Nevertheless, the extent of exposure among the population at risk is still uncertain. Based on probabilistic population sampling, between October and December 2016 we conducted household-based seroprevalence studies in four different cities in Colombia, South America (Cúcuta, Neiva, Sincelejo and a sector of the city of Medellín). Over 2400 participants were enrolled, provided a blood sample and answered a questionnaire assessing risk factors for exposure. Prior infection by dengue (DENV), ZIKV and CHIK was ascertained using a multiplex recombinant antigen-based microsphere immunoassay measuring IgG against the three viruses. We found large variation in seropositivity, suggesting large variation in the rate of infection between the four cities. For DENV, seropositivity varied from 48.9 (CI 44.8 - 53.0) to 88.9 % (CI 86.1 - 91.3); for CHIK, seropositivity varied from 7.1 % (CI 5.2 - 9.4) to 72.3 % (CI 68.7 - 75.8); while for ZIKV, seropositivity varied from 6.7% (CI 4.8-9.0%) to 65.9 (CI 62.0 - 69.6). The increase in DENV seropositivity with age confirmed the endemic nature of its transmission, whereas exposure to both ZIKV and CHIK appeared unrelated to age confirming their epidemic nature. Among the four cities, Medellin had the lowest seroprevalence for all the three viruses measured. Interestingly, history of DENV or ZIKV disease in the past was not associated with antibody presence against these viruses. In contrast, having been previously clinically diagnosed with CHIK was strongly associated with being seropositive to CHIK (OR 10.32; 95% CI 7.20 - 14.79) and 41.16% of individuals who tested positive for CHIK IgG reported presenting symptoms associated to this infection in the past. This study provides the first estimation of population attack rates and exposure levels to two emerging arboviral infections in Colombia, a Dengue endemic country, and provides key elements towards the general understanding of the transmission patterns of arboviral infections.

942

EVALUATING DIFFERENCES IN ZIKA VIRUS DIAGNOSTIC TEST RESULTS BY SPECIMEN TYPE AMONG PREGNANT WOMEN DURING THE ZIKA VIRUS OUTBREAK, PUERTO RICO 2016

Asher Rosinger[1], Sascha Ellington[2], Janice Perez-Padilla[3], Samantha Olson[2], Regina Simeone[2], Caitlin Pedati[4], Betsy Schroeder[5], Jorge L. Munoz-Jordan[3], Laura E. Adams[3], Romeo Galang[2], Miguel Valencia-Prado[6], Candimar Colón[3], Mary Goodwin[2], Dana Meaney-Delman[2], Lyle Petersen[7], Denise Jamieson[8], Carmen Deseda[9], **Margaret Honein**[2], Brenda Rivera-García[6], Carrie Shapiro-Mendoza[2]

[1]The Pennsylvania State University, State College, PA, United States, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Centers for Disease Control and Prevention, San Juan, PR, United States, [4]Nebraska Department of Health and Human Services, Nebraska City, NE, United States, [5]Indiana State Department of Health, Indianapolis, IN, United States, [6]Puerto Rico Department of Health, San Juan, PR, United States, [7]Centers for Disease Control and Prevention, Fort Collins, CO, United States, [8]Emory University, Atlanta, GA, United States, [9]Puerto Rico Department of Health, Atlanta, GA, United States

Zika virus (ZIKV) infection during pregnancy can cause adverse outcomes such as microcephaly, brain abnormalities, eye abnormalities, and other problems at birth. To help women and infants, early identification of ZIKV infection is essential. To evaluate the difference between ZIKV diagnostic tests by different specimen types and inform an optimal strategy for diagnosis of ZIKV infection among pregnant women to identify those needing additional monitoring. From October 1st to November 4, 2016, 532 pregnant women with no prior positive ZIKV test were recruited during prenatal visits and provided serum, urine, and whole blood for ZIKV nucleic acid testing (NAT) and immunoglobulin M (IgM) testing. For NAT, specimens were tested by the Trioplex Real-Time RT-PCR assay; if positive, specimens were tested using the Singleplex ZIKV assay to confirm. A positive by NAT or IgM indicates a recent ZIKV infection. Data were collected on patient age, trimester of pregnancy, ZIKV symptoms, and days since symptom onset. Women were considered symptomatic if ZIKV symptoms were present during specimen collection. Of 532 women, 495 (93.1%) were asymptomatic and 37 (7.0%) were symptomatic. Among asymptomatic women, 40/489 (8.2%) tested positive by IgM and 10/490 (2.0%) tested positive by NAT. Among positive NAT samples, 7 were positive in serum, 5 in whole blood, and 0 in urine. Among symptomatic women, 4/37 (10.8%) tested positive by IgM and 1/37 (2.7%) tested positive by NAT (serum and whole blood). Only one asymptomatic pregnant woman tested positive by both NAT (serum and whole blood) and IgM. There was little overlap in positive ZIKV test results by different diagnostic tests and specimen types. The majority of women tested were asymptomatic; however, positive ZIKV test results were identified among 10% (49/490) of women by at least one diagnostic test and specimen type. This data may inform guidance for testing pregnant women living in areas with ongoing risk of ZIKV infection by both NAT and IgM tests to identify pregnancies that require additional monitoring.

943

UNEXPECTED PROPERTIES OF A ZIKA NS2B EPITOPE SUGGEST ITS POTENTIAL AS A BIOMARKER FOR DIAGNOSIS AND PROGNOSIS

Felix Loeffler[1], Roberto Lins[2], Nico Fischer[3], Isabelle Viana[2], Catarina Cataldi[2], Bruno Leite[2], Tereza Magalhaes[4], Marli Tenorio Cordeiro[2], Ernesto T. Marques[5], **Thomas Jaenisch**[3]

[1]Max Planck Institute of Colloids and Interfaces, Potsdam, Germany, [2]Oswaldo Cruz Foundation, Recife, Brazil, [3]Heidelberg University Hospital, Heidelberg, Germany, [4]Colorado State University, Fort Collins, CO, United States, [5]University of Pittsburgh, Pittsburgh, PA, United States

Latin America and the Caribbean are facing an epidemic of three co-occuring arboviruses - Dengue (DENV), Chikungunya (CHIKV), and Zika (ZIKV). Major efforts have been made to develop reliable diagnostic tools, capable of differentiating between Zika and other Flavivirus infections. However, clinical overlap and cross-reactivity in serological assays between Flavivirus family members remain a main challenge. We postulate that ZIKV-specific epitopes can allow for a specific serological detection. Therefore, we translated the proteomes of 15 different ZIKV and 211 DENV strains (retrieved from NCBI database) into overlapping linear 15-mer peptides on high-density peptide arrays. To identify antibody response profiles differentiating between ZIKV and DENV infections, 84 clinically well-characterized patient and control serum samples were screened with peptide arrays. Comparison groups included (1) acute *vs.* convalescent adults, stratified by previous DENV background, (2) mother-infant pairs, and (3) neuro-Zika patients. Our data shows specific IgG responses towards peptides from the NS1 protein of DENV and peptides from the NS2b protein of ZIKV in convalescent samples, whereas background signal in control samples was low. Interestingly, no differences in the ZIKV-specific antibody profiles were observed, when comparing samples with or without DENV background. We could identify a 20mer epitope in the NS2b protein region, which may serve as a biomarker for specific diagnostics and a candidate target for drug development. In our initial microarray-based study, this marker shows high sensitivity and specificity. The reactivity of this NS2b epitope was also evaluated against a sample set with confirmed DENV or ZIKV infection only, whereas 71% of subjects possessed NS2b-specific antibodies. The affinity of this epitope to the respective human IgG antibodies is currently being assessed by microscale thermophoresis and a fusion protein was engineered, which will be used to elicit neutralizing antibody responses in future vaccination approaches. [Eur. patent registration EP17209651.3; 21 Dec 17]

NEUROLOGICAL SEQUELAE ASSOCIATED WITH ACQUIRED ZIKA VIRUS INFECTION IN CHILDREN

Jill F. Lebov[1], Linda M. Brown[1], Teresa Alemán Rivera[2], Norma Pugh[1], Stephen R. Hooper[3]

[1]RTI International, Research Triangle Park, NC, United States, [2]Universidad Nacional Autónoma de Nicaragua, León, Nicaragua, [3]University of North Carolina, Chapel Hill, NC, United States

Although studies have evaluated biochemical pathways for congenital Zika virus (ZIKV) infection and related severe neurodevelopmental fetal and neonatal outcomes, research on health outcomes related to postnatally acquired ZIKV infection in children is lacking. Reports of acute central nervous system disease in adults and adolescents secondary to ZIKV infection suggest that acquired ZIKV infection may impact neurological health (e.g., neuropsychological deficits, long-term fatigue, and spinal cord lesions with paresthesia and muscle weakness). To better understand the epidemiology of neurological sequelae of acquired ZIKV infection in children, we conducted a cohort study of 36 ZIKV-infected and 35 uninfected children in León, Nicaragua. Children were evaluated for neurological symptoms (e.g., self-reported history of fatigue, headaches, seizures, memory loss, changes in vision and hearing; and observed visual acuity, facial and limb strength, reflexes, cold touch and vibration response) using a clinical neurological exam at baseline and for neurodevelopmental functioning (e.g., executive function, visual-spatial thinking, processing speed, attention, behavior) 6 months later. At baseline, 14 children were aged 2-6, 28 aged 7-12, and 29 aged 13-17, and 56% percent of children were female. ZIKV-infected children were slightly younger than uninfected children, but the sex distribution was similar. We found no statistically significant differences in neurological symptoms or neurodevelopmental function by ZIKV status. However, several characteristics were more prevalent among infected vs. uninfected children: decreased speed of thought (35% vs. 28%); aggressive behavior (45% vs. 33%); attention problems (45% vs. 27%); rule-breaking behavior (38% vs. 21%); limited cognitive efficiency (86% vs. 64%); and limited verbal ability (27% vs. 9%). Of note, somatic problems and lower non-verbal IQ were more common among uninfected children. Although limited by a small sample size, this study is the first to systematically compare short-term neurological sequelae among children with and without acquired ZIKV infection.

945

REPURPOSING NOVOBIOCIN AS A FLAVIVIRUS PROTEASE INHIBITOR

Jasper Chan, Shuofeng Yuan, Kenn Chik, Cyril Yip, Kah-Meng Tee, Kin-Kui Lai, Richard Kao, Kwok-Yung Yuen

The University of Hong Kong, Hong Kong, Hong Kong

Flaviviruses such as yellow fever virus (YFV), dengue virus (DENV), West Nile virus (WNV), Japanese encephalitis virus (JEV), and Zika virus (ZIKV) continue to be global public health threats. Currently, there are limited treatment options for medically important flavivirus infections. We previously reported the *in vitro* and *in vivo* antiviral activity of novobiocin against the closely related ZIKV through inhibition of the ZIKV NS2B-NS3 protease. In this study, we expanded from these established results to investigate whether novobiocin also inhibits the protease activity of other medically important flaviviruses. The *in vitro* antiviral activity of novobiocin against DENV, WNV, and JEV was assessed in Vero and Huh-7 cells using cytopathic effect inhibition, viral load reduction, and plaque reduction assays. A fluorescence-based protease inhibition assay was used to assess the anti-flaviviral protease inhibitory activity of novobiocin. Molecular docking was performed to predict the binding between novobiocin and the proteases of DENV, WNV, and JEV. Novobiocin inhibited DENV, WNV, and JEV in Vero and Huh-7 cells in cytopathic effect inhibition, viral load reduction, and plaque reduction assays at low micromolar concentrations. The functional protease inhibition assay showed that novobiocin inhibited the protease activity of all three flaviviruses. Molecular docking predicted that novobiocin bound to the viral proteases with high stability. Our study showed that novobiocin inhibited medically important flaviviruses *in vitro*. The likely mechanism is through inhibition of the viral proteases. Further studies should be conducted to assess whether novobiocin possesses similar antiviral activity through inhibition of viral protease activity of other medically important flaviviruses. Clinical trials should be considered to assess the treatment effects of novobiocin in patients infected with these flaviviruses.

946

FORECASTING ZIKA INCIDENCE USING DENGUE SURVEILLANCE DATA FROM COLOMBIA

Henri Chung, Guido España, Amir Siraj, James Soda, Alex Perkins

University of Notre Dame, South Bend, IN, United States

Effective public health response to infectious disease outbreaks stands to benefit from accurate forecasts. The recurring seasonal nature of vector-borne disease incidence in countries where diseases such as dengue are endemic has resulted in the use of time series to inform models for forecasting future disease incidence. However, time series analyses are limited in their ability to make accurate predictions when there is little or no prior data available, such as during the recent 2015-2016

Zika epidemic in Colombia. In this increasingly common context of a disease emergence event, data from diseases with similar ecology and epidemiology could be used to form a basis of prior understanding for forecasting the emerging disease of interest. Similar to Zika virus, dengue virus is transmitted primarily by the *Aedes aegypti* mosquito and has epidemiological characteristics, such as incubation period and duration of immunity, similar to Zika. Here, we fitted time series models to weekly dengue incidence data from 2007-2015 at the departmental level in Colombia to predict peak time, peak height, and cumulative incidence of the Zika epidemic during the 2016 season. Individual models and predictions were made for each department, accounting for geographic differences in transmission. We compared our predictions to Zika incidence data and categorized our results based on the strengths of seasonality in the data. Our results suggest that model performance was heavily dependent on the strength of seasonality in departmental incidence. Models fitted to data from departments with stronger seasonality performed better at forecasting peak height and cumulative incidence than those fitted to data from departments with more irregular seasonal patterns of dengue incidence. However, the models we used were unable to accurately predict peak week, irrespective of seasonality in a region. Our results show some promise for formalizing the use of data from historically endemic diseases in forecasting emerging diseases, but at the same time they highlight limitations about the contexts in which doing so may or may not be successful.

947

DURATION OF INFECTIOUS ZIKA VIRUS

Freddy A. Medina, Giselle Torres, Jenny Acevedo, Sharon Fonseca, Leslie Casiano, Carlos De Leon, Gilberto A. Santiago, Katherine Doyle, Tyler M. Sharp, Gabriela Paz-Bailey, Jorge L. Muñoz-Jordán

Centers for Disease Control, San Juan, PR, United States

Zika virus (ZIKV) has recently caused a large epidemic in the Americas associated with birth defects. Although ZIKV is primarily transmitted by Aedes spp. mosquitoes, ZIKV RNA is detectable in blood and semen of infected individuals for weeks or months, during which time sexual and other modes of transmission are possible. However, viral RNA is expected to be detectable for longer than infectious virus is present. We determined the frequency of isolation of infectious virus from semen and serum samples prospectively obtained from a cohort of patients in Puerto Rico. Positive isolation was confirmed by cytopathic effect, increase in virus genome copy equivalents (GCE), immunofluorescence, and quantitation of infected cells by flow cytometry. These criteria confirmed infectious virus in semen from 8 of 97 patients for up to 38 days after initial detection when virus loads are higher than $1.4x10^6$ GCE/mL. Two serum isolates were obtained from 296 patients. One of these came from an aymptomatic individual. These findings can help inform important prevention guidelines for persons that may potentially be infected and transmit ZIKV sexually.

948

CHARACTERIZATION OF ATTENUATING AND COMPENSATING MUTATIONS IN DOMAIN III OF THE WEST NILE VIRUS ENVELOPE PROTEIN

Maria D. Alcorn, David W. Beasley

University of Texas Medical Branch, Galveston, TX, United States

West Nile virus (WNV) is a mosquito-borne flavivirus that can cause severe neuroinvasive disease often resulting in death or long term neurological sequelae. WNV is a global pathogen that is endemic in the United States, and for which no licensed vaccines or therapeutics are available for human use. The envelope (E) protein of flaviviruses has three structural domains and is the major component of the virion surface. Domain III of E (EIII) is the putative receptor-binding domain, and contains epitopes recognized by virus-specific potently neutralizing antibodies, although all three domains are targets for neutralizing antibodies. Mutagenesis of surface exposed EIII BC loop residues (aa 329-333) has been shown to affect the antigenicity and/or infectivity of WNV. Several non-conservative mutations at the highly conserved amino acid residue G331 were not tolerated. However, mutation to G331A yielded a virus that had altered antigenicity, moderately restricted growth in Vero cells, and a highly attenuated phenotype in mouse models of neuroinvasive disease, including in immunodeficient mice. Recovery of viruses from mice that succumbed to G331A WNV infection has identified putative compensating mutations that independently partially restore a neuroinvasive phenotype. This study aims to identify the potential mechanism(s) of attenuation that may be associated with G331A mutation. Recombinant WNV EIII and live infectious clone-derived WNV will be used to assess the effects of G331A and putative compensating mutations on structure and stability of WNV and WNV EIII, and whether the mutations affect WNV interactions with target cells *in vitro* and/or *in vivo*.

949

METAGENOME ANALYSIS OF WEST NILE VIRUS AND OTHER ARBOVIRUSES IN CULEX MOSQUITOES FROM THE SAN GABRIEL VALLEY, CALIFORNIA

Jun Hang[1], Kimberly Nelson[2], Yu Yang[1], Alice N. Maina[3], Angela Brisco[2], Jared Dever[2], Allen L. Richards[3], Richard G. Jarman[1]

[1]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]San Gabriel Valley Mosquito and Vector Control District, West Covina, CA, United States, [3]Viral and Rickettsial Diseases Department, Silver Spring, MD, United States

California has its unique warm climate and landscapes favorable for the proliferation of disease transmission vectors. Vector-borne pathogens including arthropod-borne viruses (arboviruses) remain a serious threat to the public health requiring constant vector control and disease surveillance. In June to September of 2017, 1,522 pools of Culex mosquitoes (11,559 specimens) from 23 cities in the San Gabriel Valley, California were collected and tested for arboviruses. Approximately 10% of the pools were positive for West Nile virus (WNV). Random reverse transcription, PCR amplification and next-generation sequencing (NGS) were conducted for 81 WNV positive pools for a metagenome analysis of WNV and other arboviruses. Moreover, methods of whole genome amplification and enrichment using pan-viral-pathogen probes were applied to acquire WNV genome sequences for genome-wide phylogeny and variation determination. The sequence-based taxonomic classification identified eukaryotic, bacterial, viral and unclassified genetic material in the Culex mosquito pools. Additional viruses, other than WNV, were found in 50 out of the 81 mosquito pools (61.7%). These viruses shared various degrees of nucleotide sequence similarity with viral sequences in GenBank, which included sequences from Alphamesonivirus, Biggievirus, Bunyavirus, Cordoba virus, Culex flavivirus, Marafivirus, Houston virus, Negevirus, etc. WNV genome analysis revealed that these viruses belong to the genetic lineage I, which is the same as for the clinical WNV isolates in the United States. The genome sequence that encodes a polyprotein with the expected length of 3,433 amino acids is genetically homologous with WNV genomes from mosquitoes, birds and humans in the U.S., with a small number of nucleotide differences and a few amino acid substitutions. Further genetic, phylogenetic and taxonomic characterization of these arboviruses, and the deep analysis of genetic variation of the mosquito-borne WNV and their relationship with the WNVs in avian and clinical specimens will enhance knowledge-based disease surveillance and control of arboviral infections.

950

ORAL SHEDDING OF JAPANESE ENCEPHALITIS VIRUS IN INFECTED SWINE SPECIES

Yan-Jang S. Huang, Amy C. Lyons, So Lee Park, Victoria B. Ayers, Susan M. Hettenbach, Stephen Higgs, Dana L. Vanlandingham

Kansas State University, Manhattan, KS, United States

Japanese encephalitis virus (JEV) is a zoonotic mosquito-borne flavivirus maintained among swine and avian species as amplifying hosts in the Asian Pacific region. Infection of pigs with JEV can cause rapid onset of viremia, which supports the infection of competent mosquitoes. Systemic infection that allows viral dissemination into various organs has also been reported. Although the detection of JEV in oronasal tissues of experimentally infected pigs has been attributed to the transmission of JEV in the absence of arthropod vectors under laboratory conditions, quantities and duration of viral shedding during the infection process of JEV in pigs remains unclear. In this study, shedding of JEV was monitored in two JEV challenge models based on domestic pigs and miniature pigs with feral swine phenotypes. Oral fluids were collected from infected animals using a noninvasive rope-based technique followed by quantitative detection of the viral genome. Maximal viral shedding coincided with peak viremic titers at the acute phase of infection. Presence of JEV genomes in oral fluids persisted after the clearance of detectable viremia. Consistent with the detection of JEV in the lymphoid tissues at the convalescent phase of diseases, prolonged periods of JEV oral shedding into the environment provides the basis for our understanding of persistent infection of JEV in infected swine species and its transmission in the absence of competent vectors. The detection of viral genomes also demonstrated the feasibility and advantage of using oral fluids as a noninvasive sampling approach to improve existing diagnostic and surveillance methods in endemic regions.

951

CROSS REACTIVITY BETWEEN WEST NILE VIRUS AND ST. LOUIS ENCEPHALITIS VIRUS ASSAYS IN FLAVIVIRUS NEUROINVASIVE DISEASE CASES IN LOUISIANA

Kaitlyn A. Hardin[1], Raoult C. Ratard[2], Christine Scott-Waldron[2]

[1]University of California Los Angeles Medical Center, Los Angeles, CA, United States, [2]Louisiana Office of Public Health, New Orleans, LA, United States

Serolologic assays are widely utilized in the diagnosis of flavirviral clinical disease and in public health surveillance. Previous studies have shown high rates of cross-reactivity between closely related members of the Flavivirdae family. We examined cross-reactivity between West Nile and St Louis Encephalitis serologic assays in 616 cases with presumed or confirmed flaviviral neuroinvasive disease in Louisiana. A total of 291 of 458 cases (63.5%) tested for both viruses had cross-reactivity. Of the 444 West Nile virus neuroinvasive disease cases tested, 286 (64.4%) had positive serologic tests for St Louis Encephalitis. Five of the 14 (35.7%) St Louis Encephalitis cases tested had positive serologic tests for West Nile virus. Cross-reactivity was high for both IgM and IgG tests. Cross reactivity in our large number of cases was higher than many previous estimates. As flaviviruses continue to spread, clinicians, researchers and public health personnel should be aware of the limitations of serologic assays in diagnosis and surveillance, especially in areas of the world with co-occurring viruses.

952

EXPOSURE OF FREE RANGING BIRDS TO ST. LOUIS ENCEPHALITIS AND WEST NILE VIRUSES (FLAVIVIRUS) IN AGRICULTURE AND CATTLE RAISING LANDSCAPES IN ARGENTINA

Ana P. Mansilla[1], Diego Gallego[1], Aitue Farana[1], Mikel Larrea[1], Romina Gallardo[2], Diego L. Arias Builes[2], Brenda S. Konigheim[2], Juan Manuel Grande[1], **Adrian Diaz**[3]

[1]Instituto de Ciencias de La Tierra y Ambientales de La Pampa - CONICET, Santa Rosa, Argentina, [2]Instituto de Virología - Universidad Nacional de Córdoba, Córdoba, Argentina, [3]Instituto de Virología - Universidad Nacional de Córdoba / Instituto de Investigaciones Biológicas y Tecnológicas - CONICET - UNC, Córdoba, Argentina

Anthropogenic changes affect biological communities of host and vectors driving arbovirus activity. In general, urban and agricultural landscapes host less avian and mosquito diversity and frequently these are dominated by few species. The St. Louis encephalitis (SLEV) and West Nile viruses (WNV) are infectious agents that have emerged and re-emerged worldwide. The aim of this work was to evaluate activity of SLEV and WNV in bird communities in agricultural and cattle raising landscapes. Field work was carried out in four different sites in La Pampa province (Argentina) between February and June 2017 (summer and fall). Avian sera samples were analyzed by plaque reduction neutralization test. Generalized Linear Models were performed to determine the effect of bird species and sampling site on the infection of SLEV/WNV. Neutralizing antibodies against SLEV were found in 45 out of 348 samples (12.9%) while WNV seroprevalence overall was 3.4% (12/348). House Wren (*Troglodytes aedon*), House Sparrow (*Passer domesticus*), Monk Parakeet (*Myiopsitta monachus*), Rufous Hornero (*Furnarius rufus*), Rufous-collared Sparrow (*Zonotrichia capensis*) and Picui Ground-dove (*Columbina picui*) were the most exposed avian species to SLEV. On the other hand, Shiny Cowbird (*Molothrus bonariensis*), Rufous Hornero (*Furnarius rufus*), Monk Parakeet (*Myiopsitta monachus*), and Picui Ground-dove (*Columbina picui*) showed the highest seroprevalence values for WNV. The sampling site was a significant variable affecting the chance to detect an infected bird by SLEV/WNV. Sites located in northern area showed higher seroprevalence values than those located southern. Our data confirm the geographic expansion of WNV in Argentina from center region to southern latitudes. Northern area of La Pampa is subject of intense agricultural activities (soy, corn, wheat) whilst southern area has a mixed of agricultural and cattle raising activities. These preliminary data indicate a potential positive effect of agricultural activities over the SLEV/WNV activity.

953

DETECTION AND QUANTIFICATION OF WEST NILE, RIFT VALLEY FEVER, AND DENGUE FEVER VIRUSES FROM DRIED BLOOD SPOTS TO IDENTIFY ZOONOTIC POTENTIAL

Emma Hale, Tonia Schwartz, Sarah Zohdy

Auburn University, Auburn, AL, United States

Wildlife, non-human primates (NHPs) in particular, can serve as reservoirs for arboviruses such as Dengue Fever, West Nile Fever, and Rift Valley Fever Viruses, which can all be found in human populations in Madagascar. To better understand the zoonotic potential of Malagasy wildlife species to act as reservoirs of these viruses, methods for rapid, minimally invasive sample collection and preservation are necessary. With this study we aim to (1) validate the use of dried blood spots on TropBio cards as a method for detecting RNA viruses, (2) to determine the prevalence of these viruses in wild NHP species (lemurs of Madagascar). To validate the protocol, house mouse (*Mus musculus*) blood was spiked with non-infectious viral RNA or inactivated viral particles in a dilution series. The spiked blood and applied to TropBio cards, dried, and preserved at room temperature over several time-points. RNA was isolated from the cards and the target viral RNA was detected by qPCR. Lemur blood samples were collected from

intact forest and deforested regions of Madagascar. We are testing these samples for each of the viruses using qPCR and the prevalence will be presented.

IVERMECTIN-TREATED BIRD FEED TO CONTROL WEST NILE VIRUS TRANSMISSION

Chilinh Nguyen, Meg Gray, Timothy A. Burton, Soleil L. Foy, Claudia Ruckert, John Foster, Wojtek S. Kuklinski, Brian D. Foy

Colorado State University, Fort Collins, CO, United States

Arbovirus transmission control with insecticides sprayed into the environment are often reactive interventions and inadequate for localized control during outbreaks, can be poorly-targeted, and often face opposition due to environmental and toxicity concerns. In this study, we developed endectocide-treated feed as a systemic endectocide for wild birds to target blood feeding *Culex tarsalis,* the primary West Nile virus (WNV) vector in the Western United States, and we conducted preliminary tests on the effects of deploying this feed in the field. In lab tests, ivermectin (IVM) in a powder formulation was the most effective endectocide tested against *Cx. tarsalis*. Chickens and wild Eurasian collared doves fed solely on treated bird feed concentrations up to 200 mg IVM/kg feed exhibited no signs of toxicity, and most *Cx. tarsalis* that blood fed on these IVM-fed birds died compared to control birds. Mosquito survivorship following blood feeding correlated with IVM serum concentrations at the time of blood feeding, which dropped rapidly after the withdrawal of IVM feed. Two pilot field trials were conducted during the summers of 2016 and 2017. The 2016 season was designed with three field sites, each with a central IVM-treated bird feeder with mosquito traps at 10 m and 150 distances from the feeder. Results from 2016 showed that wild birds frequently visited the IVM-treated feeders and there was an observable trend where the 150 m traps that are expected to be beyond the zone of control had more WNV-positive *Cx. tarsalis* pools compared to 10 m traps. The 2017 trial was designed with three control and three IVM sites, where each site had an array of three bird feeders around a central mosquito trap. Results from 2017 demonstrated that 87% of birds captured around IVM bird feeders had detectable levels of IVM in their blood, and entomological data suggested the treatment may have reduced WNV transmission around treated bird feeders. With further development, deployment of ivermectin-treated bird feed might be an effective hyper-localized WNV transmission control tool.

955

INTRAHOST GENETIC DIVERSITY OF WEST NILE VIRUS IN HORSE BRAIN AND PLASMA

Dhani Prakoso[1], Michael J. Dark[1], Anthony F. Barbet[1], Marco Salemi[1], Helen Piontkivska[2], Sarah E. Beachboard[1], Maureen T. Long[1]

[1]University of Florida, Gainesville, FL, United States, [2]Kent State University, Kent, OH, United States

In 1999, a highly virulent West Nile virus (WNV) was introduced to North America resulting in more than 28,012 equine infections. WNV has been shown to be genetically diverse within the mosquitoes in nature. These genetic variations are essential in the adaptation of flaviviruses in a new and changing environment and host. A genetically diverse virus population would seem to have an advantage on adaptation because the virus has pre-existing variants which are better adapted to a new and changing environment. Other than in the mouse, there is limited information regarding viral diversity, tissue tropism, manifestation, and severity of this disease in mammalian tissues. Little is known regarding viral evolution within the natural vertebrate host. A wide variety of vertebrate hosts are infected with WNV, but only humans and horses develop significant neurological clinical disease and much can be derived by studying pathogenesis in the horse. The goal of this project was to sequence the WNV genes to investigate the hypothesis that different viral variants are present in plasma and brains of WNV infected horses. Five brain tissues and plasma of two horses were sequenced using Pacific Biosciences (PacBio) sequencing to investigate genetic variation in the NS4B gene of the WNV. The NS4B gene was chosen for this preliminary sequencing run because of the size, signal noise, and conserved sites. The mean read quality of the WNV NS4B gene sequences obtained from PacBio sequencing was 99.18% with 22 average passes. Brain had the highest number of total virus variants with most of the variants were in the cerebrum of the horses. DNA sequencing showed significant difference in sequence variation and reads in different days post infection. This preliminary finding indicated that WNV could adapt in different tissues and generated more variation overtime in the horses. More WNV gene sequences and phylodynamic analysis are on the way to further analyze the WNV diversity in horse brain and plasma.

INFLUENCE OF EARLY INFLAMMATION, TRACE ELEMENTS, AND ANTIBIOTIC EXPOSURE ON IMMUNE RESPONSES TO ROTAVIRUS VACCINATION

Jessica L. Prince-Guerra[1], Christopher Miller[2], Melissa Delgado[1], Laura Calderwood[3], Rachel M. Burke[3], Paulina A. Rebolledo[2], Parminder Suchdev[1], Rita Revollo[4], Volga Iñiguez[5], Juan Leon[1]

[1]Hubert Department of Global Health, Rollins School of Public Health, Emory University, Atlanta, GA, United States, [2]Emory School of Medicine, Atlanta, GA, United States, [3]Department of Epidemiology, Rollins School of Public Health, Emory University, Atlanta, GA, United States, [4]Servicio Departamental de Salud, La Paz, Plurinational State of Bolivia, [5]Instituto de Biología Molecular y Biotecnología, La Paz, Plurinational State of Bolivia

Rotavirus (RV) is the leading cause of diarrheal mortality in children globally. Oral RV vaccines are less effective in resource-limited settings, where the greatest RV disease burden occurs. Immunological responses to the RV vaccine may be influenced by systemic inflammation or malnutrition, such as trace element deficiencies. Antibiotic use, through perturbing the gut microbiome, is also hypothesized to impact RV vaccine responses. We tested these possible mechanisms in a RV vaccine immunogenicity study of 305 infant-mother pairs from El Alto, Bolivia. Infants received two doses of the monovalent RV vaccine (at ~2 and 4 months of age) and were followed from 2 weeks to 12-18 months of age. RV-specific IgA titers were measured in infant serum at 2 and 6 months, and seroconversion was defined as a four-fold or greater increase in geometric mean titers (GMT). Systemic inflammation (α-1-acid-glycoprotein [AGP], C-reactive protein [CRP]) and trace element concentrations (copper, iron, zinc, magnesium, and calcium) were measured in serum at 2 and 6 months by ELISA and inductively coupled plasma atomic emission spectrometry. Six-month serum copper was positively correlated with AGP ($\rho = 0.54$; $p < 0.01$) and CRP ($\rho = 0.48$; $p < 0.01$), but serum iron was negatively correlated with AGP ($\rho = -0.19$; $p < 0.01$) and CRP ($\rho = -0.26$; $p < 0.001$). The fold change in rotavirus IgA GMT between pre- and post-vaccination was negatively associated with 6-month serum CRP ($\rho = -0.16$; $p = 0.005$) and copper ($\rho = -0.14$; $p = 0.01$), but positively associated with 6-month serum iron ($\rho = 0.11$; $p < 0.05$). Antibiotic prescriptions prior to 6 months were extracted from clinical chart reviews for a subset of infants (135). Thirty-three (24%) received at least one course of antibiotics. Antibiotic prescription was not significantly associated with RV IgA seroconversion (OR = 1.1; 95% CI = 0.5 - 2.6; $p = 0.85$). We hypothesize that inflammation is driving the association between trace elements and RV vaccine immune responses. It will be important to test this hypothesis to assess the relative contributions of both inflammation and trace elements on impaired RV vaccine responses in global infant cohorts.

957

MELITTIN AS REGULATOR OF APOPTOSIS LATE IN CHRONIC CELL LINE INFECTED WITH HTLV-1 ADULT T-CELL LEUKEMIA / LYMPHOMA

Sophia I. Velarde, Giovanni M. Lopez, Michael J. Talledo

Institute of Tropical Medicine Alexander von Humboldt; Universidad Peruana Cayetano Heredia, Lima, Peru

The human T-cell leukemia virus type-1 has in Perú a prevalence of 5% to 10% people infected globally. Perú an endemic area of which only 2% -6% of infected develop Adult T Cell Leukemia / Lymphoma (ATLL), a malignant neoplasm that has been seen to have a high proliferation of infected cells. As HTLV-1 is an important risk factor for development of ATLL; we raised the question if Melittin (compound extracted from bee venom) plays a role in the proliferation of a chronic cell line infected with HTLV-1.Differents non-lytic concentrations of commercial Melittin [0.5 mM to 2.5mM] were used in cell culture exposing on the logarithmic phase both MT-2 cell line as K562 cell line (not infected with HTLV-1). The viability of these lines was observed for 48 hours and was measured with cell tracker Calcein AM Green, Anexin V and 7-AAD, to Trypan Blue Exclusion and cytometer. No increase in apoptosis late between MT-2 without treatment and at 2.5 mM melittin (0.1% to 9.5% 12% to 28% of cells in apoptosis late) with no statistically significant ($P < 0.05$) between different melittin concentrations; whereas with the uninfected cell line, a higher apoptosis increase is observed (12% to 28% of cells in apoptosis late). Our results showed that Melittin for apoptotic late K562 that control the cellular proliferation but the use of melittin in non-sublitic doses same with MT-2 no significance in apoptosis late.

GENETIC DIVERSITY OF CIRCULATING NOROVIRUS, SAPOVIRUS AND ASTROVIRUS IN A PEDIATRIC HOSPITAL AT LIMA-PERÚ

Macarena D. Vittet[1], Gerardo Sanchez[1], Mayra Ochoa[1], Fabiola Colquechagua-Aliaga[2], Dante Figueroa-Quintanilla[2], Robert Gilman[3], Mayuko Saito[4], Sarah Blythe Ballard[3], Holger Mayta[1]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Unidad de Rehidratación Oral, Instituto Nacional de Salud del Niño, Lima, Peru, [3]Department of International Health, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, United States, [4]Department of Virology, Tohoku University Graduate School of Medicine, Sendai, Japan

The most common etiological viral agents of gastroenteritis are Norovirus, Rotavirus, Sapovirus, and Adenovirus after the introduction of rotavirus vaccine. This study evaluated the genetic diversity and prevalence of Norovirus (NoV), Sapovirus (SaV), and Astrovirus (AstV). 1778 Fecal and swab samples were collected from children less than 5 years old presenting WHO's criteria for diarrhoea that attend the Hospital del Niño in Lima Peru between December of 2013 and April 2015. Control samples were collected from children attending the hospital for reasons other than diarrhoea. Samples were individually tested for NoV, Sav and AstV using RT-qPCR. Positive samples were amplified by conventional PCR and the amplification product was sequenced. Phylogenetic analysis was performed to establish genetic relationships with reference strains. Among diarrhoea cases, Norovirus was the most predominant virus (36%) followed by Sapovirus (8%) and Astrovirus (5%). We were able to identify: *(i)* among NoV positive samples, 4 and 13 genotypes from genogroups GI and GII respectively; GI.3 and GII.4 were the most predominant genotypes in each genogroup; *(ii)* among SaV positive samples the genotype GI.2 as the most predominant, *(iii)* among the AstV positive samples, the genogroups MastV1, MastV6, MastV8 were detect and MastV1 as the most predominant genogroup.Viral agents showed a high diversity among children with diarrhoea that seeks medical attention. Surveillance needs to be implemented to identify genotype changes among those viral agents, especially for vaccine development.

USING COMPLEX DATA AND DEEP LEARNING TO PREDICT RIFT VALLEY FEVER OUTBREAKS

Jochen Kumm[1], **Elysse N. Grossi-Soyster**[2], Krish Seetah[3], A. Desiree LaBeaud[2]

[1]InSightAI, Palo Alto, CA, United States, [2]Stanford University School of Medicine, Stanford, CA, United States, [3]Stanford University, Stanford, CA, United States

Disease outbreaks are difficult to predict because they rely on the alignment of multiple complex factors and circumstances, many of which have not yet been identified or are not well understood. Rift Valley fever virus (RVFV) is a vector-borne zoonotic phlebovirus that primarily infects livestock and humans via transmission by mosquito or direct contact with contaminated bodily fluids. RVFV is a Category A biodefense pathogen because it can cause life-threatening hemorrhagic fever, meningoencephalitis and organ failure in humans, and has the potential to result in catastrophic economic harm to livestock. Previous models of RVFV outbreaks in Kenya have often focused on a single data source, such as climate, or estimated the contributions of a specific metric, such as rainfall, genetic diversity, or severity of El Niño effects. Such models have identified key factors affecting outbreaks but have not delivered effective outbreak prediction. In this study, we utilized a deep learning platform trained on the history of outbreaks in Kenya. A variety of data on socio-economic and behavioral traits in multiple communities from various regions of Kenya was part of the training set. Traditional machine learning approaches, such as clustering, decision trees, and naïve Bayes were used to analyze these epidemiological data on RVFV outbreaks, but failed to provide sufficient predictive power. Deep Learning (DL) using recurrent neural networks allowed us to incorporate climate data spanning 100 years and data from the 2009 census. The resulting DL model predicted about ~80% of Kenyan outbreaks to date. The epidemiology of RVF, massive periodic outbreaks and continued spread to new areas, suggest that increased efforts and expanded data sources are needed to predict, prevent, contain, and control this economic, veterinary, and public health threat.

NON-SECRETOR HISTO-BLOOD GROUP ANTIGEN PHENOTYPE DOES NOT IMPAIR SUSCEPTIBILITY TO INFECTION WITH ROTARIX VACCINE AMONG INFANTS IN BANGLADESH

Benjamin Lee[1], Abdul Kader[2], Dorothy Dickson[1], E. Ross Colgate[1], Sean A. Diehl[1], Muhammad I. Uddin[2], Salma Sharmin[2], Shahidul Islam[2], Taufiqur R. Bhuiyan[2], Masud Alam[2], Uma Nayak[3], Josyf C. Mychaleckyj[3], Mami Taniuchi[3], William A. Petri, Jr.[3], Rashidul Haque[2], Firdausi Qadri[2], Beth D. Kirkpatrick[1]

[1]University of Vermont, Burlington, VT, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]University of Virginia, Charlottesville, VA, United States

Rotavirus (RV) is the leading cause of infectious diarrhea among infants worldwide. This occurs despite availability of oral, live-attenuated vaccines, which underperform in low-income settings. Children with non-secretor histo-blood group antigen phenotype (HBGA) have reduced susceptibility to RV diarrhea (RVD), raising concerns that non-secretors may also be less susceptible to oral, live-attenuated RV vaccines. However, direct evidence of susceptibility (or lack thereof) to vaccine strains among non-secretors is lacking. It also remains unknown if HBGA-mediated differences in RV susceptibility is limited to RVD or extends to asymptomatic infection, as seen in oral vaccination. Therefore, we investigated associations between secretor status, asymptomatic RV infection, and post-vaccination fecal vaccine shedding in PROVIDE, a Rotarix vaccine trial conducted among infants in Bangladesh. Secretor phenotyping was performed on saliva. Eleven surveillance stool specimens were collected over the first year of life, and a subset of vaccinees had additional specimens collected within

one week following both Rotarix doses. Stools were tested for RV by real-time RT-PCR; positive specimens underwent Sanger sequencing for strain confirmation. To assess HBGA in asymptomatic RV infection, we evaluated unvaccinated infants who were RVD-free through one year. Among 112 such infants, significantly fewer non-secretors experienced asymptomatic infection (12%) compared to secretors (42%; P<0.0001). We then evaluated for Rotarix shedding. Among 182 vaccinated infants, 115 (63.2%) shed Rotarix following either dose. No significant differences were seen in the proportion of non-secretors who shed Rotarix (65%) compared to secretors (60%). Non-secretors had decreased risk for natural RV infection but are successfully infected with vaccine during Rotarix challenge. These results provide the first direct evidence that susceptibility to RV vaccine is unaffected by secretor status, and that HBGA-mediated resistance to oral RV vaccines is thus an unlikely mechanism of vaccine underperformance.

Zika virus is a single stranded RNA virus and a member of the family *flaviviridae*. It is transmitted to humans by mosquito bite, sexual transmission or during pregnancy to the fetus. A large outbreak of zika disease emerged in Yap State, Polynesia in 2007 and again in French Polynesia in 2013. The latest outbreak in Brazil in 2015 produced severe syndrome of microcephaly in infants. Real-time Reverse transcription Polymerase Chain Reaction (rRT-PCR) is the primary method used to detect zika virus in samples. Being able to isolate virus is also very useful and allows analysis of virus evolution, epidemiology, molecular markers of virulence or attenuation and other factors that may be implicated in disease pathogenesis and/or protection from the disease. In this study, two procedures of viral isolation are described using various types of clinical specimens, e.g., sera, plasma, whole blood, urine. Specimens that were rRT-PCR positive (Ct value ≤38) were used for virus isolation using *Toxorhynchitis splendens* mosquito (*Tox*) and tissue culture (C6/36, *Aedes albopictus*) inoculation. The specimens originated from various sites in Thailand and the Philippines. All specimens were collected during year 2014-2018. From zika virus PCR positive serum samples, 9/13 (69%) were successfully isolated using *Tox* while only 1/13 (7.6%) was able to be cultured in C6/36-3 blind passages. We were unable to isolate zika virus from any of the PCR positive plasma samples using *Tox* or C6/36-3 (0/4 tested). From whole blood, 2/15 (13%) were isolated by *Tox* but none were successfully isolated using C6/36 cells. Only 1/25 (4%) urine PCR positive samples were successfully isolated in C6/36-3 but none by using mosquito inoculation. These data indicated that *Tox* mosquito inoculation provides a high success rate for zika virus isolation over C6/36 cells when using serum or whole blood samples.

962

PREVALENCE OF DENGUE VIRUS, CHIKUNGUNYA VIRUS, AND ZIKA VIRUS DETERMINED THROUGH ENHANCED SURVEILLANCE OF EMERGING INFECTIOUS DISEASES IN MALAYSIA

Tupur Husain[1], Brian Pike[1], Chee-Sieng Khor[2], Nurul-Farhana Mohd-Rahim[2], Habibi Hassan[2], Siti-Sarah Nore[2], Jefree Johari[2], Shih-Keng Loong[2], Juraina Abd-Jamil[2], Keivan Zandi[2], Jing-Jing Khoo[2], Hai-Yen Lee[2], Yvonne Ai-Lian Lim[3], Sazaly AbuBakar[2]

[1]Naval Medical Research Unit No. 2, FPO, AE, United States, [2]Tropical Infectious Diseases Research and Education Center (TIDREC), University of Malaya, Kuala Lumpur, Malaysia, [3]Department of Parasitology, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia

Peninsular Malaysia has been the site of an increase in the ability to rapidly detect disease outbreaks and accurately diagnose infectious agents, a capacity that is paramount to any public health surveillance program. The viral pathogens for dengue (DENV), chikungunya (CHIKV), and Zika (ZIKV), cause diseases of particular medical importance in that they have been detected in Malaysia previously adding to other notable historic outbreaks in Reunion Island and Latin America. Besides these viruses, there are other unique vector-borne pathogens found in Malaysia. Proper evaluation of these pathogens enables tracking of emerging infections at their potential origin sites. Implementation of syndromic surveillance protocols has enabled the surveillance and laboratory-based diagnostic testing for uncommon diseases in patients presenting to select healthcare facilities in peninsular Malaysia, such as members of the indigenous Orang Asli community and rural farm/agricultural workers living and working at the animal-human interface in the forest fringe areas. Surveillance and laboratory-based diagnostic testing for asymptomatic members of the community were performed to screen patients using serological assays and molecular detection, respectively. Patients were recruited from settlements and nearby public health clinics. By November 2017, 730 blood samples had been collected from patients that were either febrile (144) or asymptomatic (586). DENV and CHIKV were found in 10 (6.9%) and 6 (4.2%) of the samples, respectively, that were collected from febrile patients. DENV (41.6%), CHIKV (32.9%) and ZIKV (20.9%) were also found to have the highest seroprevalence among all the pathogens screened. In addition to DENV, CHIKV, and ZIKV fevers are likely to be endemic in communities living in the forest fringe areas of Malaysia but presently under-detected. These latter infections are probably not recognized due to the high prevalence of DENV, which may mask identification of the infections. Further studies with higher sample sizes from other localities would aid in obtaining a better estimate of the extent of these infections.

[1]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]Armed Forces Research Institute of Medical Sciences, Bangkok,

Thailand, [3]Royal Centre for Disease Control in place of Public Health Laboratory, Thimphu, Bhutan, [4]Walter Reed/Armed Forces Research Institute of Medical Sciences Research Unit Nepal, Kathmandu, Nepal, [5]Phramongkutklao Hospital, Bangkok, Thailand

Asia plays a major role in the global transmission of influenza A and B viruses, yet the epidemiology of influenza in tropical and subtropical Asia is not entirely clear. We therefore evaluated the temporal epidemic dynamics of influenza viruses in five Asian countries over an entire decade. Human respiratory specimens derived from year-round influenza-like illness surveillance activity in Bhutan, Cambodia, Nepal, Thailand and the Philippines during 2007- 2016 underwent complete HA segment sequencing for all subtypes. These data were collated with public HA sequences available on the Influenza Research Database (www.fludb.org) to yield curated datasets for Bhutan (n=252), Cambodia (n=73), Nepal (n=373), Philippines (n=393) and Thailand (n=1,449). The datasets were further aligned with curated public HA sequence data from all other countries to yield global alignments for sH1N1 (n = 1,110), pdm2009H1N1 (n = 9,694), H3N2 (n=7,655), B Yamagata [B Yam] (n=2,932) and B Victoria [B Vic] (n = 2,191). Maximum-likelihood phylogenetic trees were constructed for each subtype using RAxML or PhyML, and used to estimate subtype strain persistence for the five countries. Across all subtypes, there were frequent new strain introductions which had short median persistence times in Bhutan (sH1N1 = 18 days, pdm2009H1N1 = 14.5 days, H3N2 = 30 days, B Yam = 20.5 days, B Vic = 37 days), Cambodia (sH1N1 = 53 days, pdm2009H1N1 = 20 days, H3N2 = 3 days, B Yam = not detected (n=0), B Vic = 170 days), Thailand (sH1N1 = 34.5 days, pdm2009H1N1 = 1 day, H3N2 = 2 days, B Yam = 54 days, B Vic = 70 days), Nepal (sH1N1 = 63 days, pdm2009H1N1 = 27 days, H3N2 = 23.5 days, B Yam = 19 days, B Vic = 65 days) and the Philippines (sH1N1 = 78 days, pdm2009H1N1 = 32.5 days, H3N2 = 11 days, B Yam = 50 days, B Vic = 124.5 days). Influenza A and B virus epidemics in Bhutan, Cambodia, Nepal, Philippines and Thailand are characterized by repeated introductions and limited persistence of circulating strains, similar to influenza viruses in temperate regions. The longer persistence of influenza B may represent differences in epidemic dynamics between the influenza A and influenza B subtypes and warrants further study.

964

DISCOVERY OF NOVEL VIRUSES IN MOSQUITOES FROM THE UNITED STATES AND MEXICO

Jermilia Charles[1], Chandra S. Tangudu[1], Stefanie L. Hurt[1], Charlotte Tumescheit[2], Andrew E. Firth[2], Ryan C. Smith[1], Julian E. Garcia-Rejon[3], Carlos Machain-Williams[3], Lyric C. Bartholomay[4], Bradley J. Blitvich[1]

[1]Iowa State University, Ames, IA, United States, [2]University of Cambridge, Cambridge, United Kingdom, [3]Universidad Autónoma de Yucatán, Mérida, Mexico, [4]University of Wisconsin Madison, Madison, WI, United States

Metagenomics was used to identify novel and previously discovered viruses in mosquitoes from the United States and Mexico. To facilitate the identification of viruses in the U.S., 1432 mosquitoes (8 species) from Iowa were sorted into 54 pools, homogenized, filtered and inoculated onto monolayers of *Aedes albopictus* (C6/36) cells. Another 37 pools, comprised of 1359 mosquitoes (7 species) from the Yucatan Peninsula of Mexico were also processed as described above. A second blind passage was performed then total RNA was extracted from all cultures showing cytopathic effect as well as select cultures that did not and analyzed by Ion Torrent sequencing. Three novel and two previously recognized viruses were detected in the mosquitoes from Mexico. The first novel virus is a Negevirus recovered from several pools of *Aedes taeniorhynchus*. The second is a member of the *Tymoviridae* family that was isolated from *Culex quinquefasciatus*. The final novel virus is most closely related to an unclassified RNA virus known as Hubei noda-like virus 5 and was isolated from *Psorophora ferox*. The two recognized viruses identified in the Mexico collections are Culex flavivirus (family *Flaviviridae*) and Houston virus (family *Mesoniviridae*), isolated from *Culex quinquefasciatus* and *Ae. taeniorhynchus*, respectively. Culex flavivirus and Houston virus were also isolated from mosquitoes originating from Iowa. The Iowa collections also yielded two novel orbiviruses and two recognized orbiviruses. Both of the novel orbiviruses were isolated from *Aedes trivittatus*. The two recognized orbiviruses, Umatilla virus and Koyoma Hill virus, were isolated from *Ae. trivittatus* and *Aedes triseriatus*, respectively. We are currently determining the *in vitro* host ranges of these viruses by assessing their ability to replicate in 11 cell lines of human, monkey, hamster, duck, mouse, moth and mosquito (*Aedes*, *Anopheles* and *Culex*) origin.

965

EFFECT OF MASS ARTESUNATE-AMODIOQUINE DISTRIBUTION ON EBOLA-RELATED MORTALITY IN SIERRA LEONE

Stephanie C. Garbern[1], Adam R. Aluisio[1], Tao Liu[2], Derrick Yam[2], Daniel Cho[2], Shiromi M. Perera[3], Adam C. Levine[1], Adam C. Levine[1]

[1]Warren Alpert Medical School of Brown University, Providence, RI, United States, [2]Brown University, Providence, RI, United States, [3]International Medical Corps, Washington, DC, United States

There are no known treatments for Ebola Virus Disease (EVD). Although the mechanism is unknown, *in vitro* experiments have shown that the drug amodiaquine may inhibit Ebola virus activity. During the Ebola epidemic in Sierra Leone in 2014/15, the government implemented two mass drug administrations (MDA) of artesunate-amodiaquine (ASAQ), a 3-day oral malaria treatment regimen, to decrease the burden of malaria. Each MDA was implemented over a four-day period (Dec 5-8, 2014 and Jan 16-19, 2015) to chiefdoms with previously confirmed EVD cases. Mortality data for EVD+ patients admitted to three Ebola Treatment Units (ETUs) in Sierra Leone were analyzed retrospectively to evaluate the potential effect of ASAQ administration on mortality. All patients admitted to the ETUs during the days of the MDA until 10 days after (based on amodiaquine's half-life) from chiefdoms where the MDA was implemented were presumed to have received amodiaquine. The primary outcome was ETU mortality comparing EVD cases treated with ASAQ versus those not treated. Kaplan-Meier survival analyses were performed with significant differences assessed using log-rank tests. Cox proportional hazards models were used adjusting for patient age and malaria co-infection status to yield adjusted hazard ratios (aHR). In the cohort 1524 patients were treated of whom 254 had EVD. Overall mortality for EVD patients was 55.1%. EVD patients from MDA chiefdoms admitted to the ETUs during the presumed therapeutic effect window of amodiaquine had a 25% decreased risk of death compared to all other EVD+ patients, although this was not statistically significant (aHR 0.75; 95%CI 0.40-1.43). There was no evidence of reduction in mortality risk in EVD patients from MDA chiefdoms admitted during the presumed therapeutic window of amodiaquine as compared to EVD patients from non-MDA chiefdoms admitted during the same time period (aHR 1.05; 95%CI 0.29 - 3.72). Further investigation in patient cohorts known to have received amodiaquine at an individual level is needed to determine whether amodiaquine may directly modify mortality risk in EVD+ patients and the mechanism by which this may occur.

966

EARLY INTRAVENOUS FLUID THERAPY AND MORTALITY OUTCOMES AMONG PATIENTS WITH EBOLA VIRUS DISEASE: A MULTISITE RETROSPECTIVE PROPENSITY-MATCHED COHORT STUDY

Adam R. Aluisio[1], Tao Liu[2], Derrick Yam[2], Jillian L. Peters[3], Daniel K. Cho[4], Shiromi M. Perera[5], Stephen B. Kennedy[6], Adam C. Levine[1]

[1]Department of Emergency Medicine, Brown University Alpert Medical School, Providence, RI, United States, [2]Brown University, School of Public Health, Center for Statistical Sciences, Department of Biostatistics, Providence, RI, United States, [3]Warren Alpert Medical School of Brown University, Providence, RI, United States, [4]Brown University, Providence,

RI, United States, [5]International Medical Corps, Washington, DC, United States, [6]Ministry of Health, Monrovia, Liberia

This retrospective cohort study investigated the relationship between early intravenous fluid (IVF) therapy (initiated within 48 hours of care) and mortality among patients with Ebola Virus Disease (EVD) admitted to five International Medical Corps run Ebola Treatment Units (ETU) in two countries during the 2014/15 epidemic. Standardized treatments with antimicrobials and nutritional supplementation were provided to all patients, however IVF was administered based on clinical indication and resource availability. A propensity score incorporating factors associated with IVF exposure was derived and cases were matched using a caliper of <0.2. Post-matching absolute standardized bias was <0.25 for all parameters. The overall cohort was analyzed, and additionally, stratified analyses were performed based on cycle threshold (CT) values as low (>22) or high (<22), corresponding to high and low Ebola viral loads respectively. The outcome of interest was proportional mortality during care compared between cases exposed to early IVF and those not. Risk differences (RD) with 95% confidence intervals (CI) were calculated in comparative analyses. There were 424 cases analyzed, of which 257 (38.9%) received early IVF. In the propensity-matched analysis of the overall cohort mortality prevalence was 53.2% for non-IVF cases and 58.9% for IVF treated cases (RD=5.7%, 95% CI: -3.6%, 14.9%; p=0.23). In matched stratified analysis of cases with low CT values mortality prevalence was 71.1% for non-IVF cases and 70.2% for IVF treated cases (RD=0.9%, 95% CI: -10.8%, 12.6%; p=0.88). Among cases with high CT values mortality prevalence was 31.9% for non-IVF cases and 41.8% for IVF treated cases (RD=9.9%, 95% CI: -4.1%, 23.3%; p=0.17). Although mortality prevalence was greater with early IVF treatment in the overall cohort, and among cases stratified by viral loads, there were no significant differences in outcomes, suggesting minimal utility for a therapy requiring relatively high-resource allocation and greater provider risk in epidemic settings.

967

DIFFERENCES IN THE PEDIATRIC ENTERIC VIROME ACROSS WATERY, LOOSE AND FORMED STOOL CONSISTENCY TYPES

Kristen Aiemjoy[1], Eda Altan[1], Solomon Aragie[2], Dionna Fry[1], Tung G. Phan[1], Xutao Deng[1], Zerihun Tadesse[2], Kelly Callahan[3], Eric Delwart[1], Jeremy Keenan[1]

[1]University of California San Francisco, San Francisco, CA, United States, [2]The Carter Center, Addis Ababa, Ethiopia, [3]The Carter Center, Atlanta, GA, United States

Stool consistency is an important diagnostic criterion in both research and clinical medicine. Most epidemiologic studies use stool consistency, specifically 'loose or watery stool', to define diarrhea disease. We examine the pediatric enteric virome across characterized stool sample consistency to evaluate differences in viral abundance community composition. We collected stool samples from children participating in a clinical trial evaluating a water improvement intervention in the Amhara region of Ethiopia. The consistency of each fecal sample was graded according to the modified Bristol Stool Form Scale for children (mBSFS-C) before a portion of stool was preserved for viral metagenomic analysis. The number of viral reads along with the taxonomic assignments and sample characteristics were assembled using the *phyloseq* package in R. Differential abundance was determined at the genotype level using negative-binomial modeling in the *DESeq2* package in R. Of 446 censured children who were eligible to participate, 317 children presented for the study visit examination and 269 provided stool samples. The mean age of children with stool samples was 2.7 years old. Stool samples were grouped into 29 pools according to stool consistency type. Species richness was highest in watery-consistency stool and decreased consistently as stool consistency became firmer (Spearman's r=–0.45, p=0.013). The median number of distinct viruses (richness) was 6.5 in Type 5 (watery) stool, 5.5 in Type 4, 4.0 in Type 3, 3.0 in Type 2 and 2.0 in Type 1 (hard pellets). The greatest $\log_2$ fold change in differential abundance comparing loose or watery to formed stool was for Norovirus GII (7.64) followed by Aichivirus A (5.92), Adeno-associated dependoparvovirus A (5.8), Enterovirus A (4.85), Human mastadenovirus C (3.84), Cosavirus A (3.20), and Anellovirus (3.09). In conclusion, we documented a difference in pediatric enteric viromes according to mBSFS-C stool consistency category, both in species richness and composition. The findings may support the content validity of using stool consistency as a proxy for viral infection.

968

EPIDEMIOLOGY OF G12 ROTAVIRUS AMONG INDIAN CHILDREN IN A MULTI-CENTRIC HOSPITAL-BASED SURVEILLANCE FROM 2005 TO 2016

Samarasimha Reddy N, Sidhartha Giri, Gagandeep Kang

Christian Medical College, Vellore, Vellore, India

G12 rotavirus strains were first isolated in India in 2001, and have emerged as a predominant strain causing diarrhea in the under-five age group. The Christian Medical College(CMC), Vellore, Child Jesus Hospital, Trichy from south India, and St. Stephen's hospital, Delhi from north India took part in hospital-based surveillance from December 2005 to July 2016 to evaluate rotavirus associated diarrhea in children <5 years of age. Stool samples were collected from children within 48 hours of admission after obtaining informed consent from parents/guardian. 6907 children were recruited across three sites of which, stool samples was not collected for 5 children, and for 10 children sample was inadequate for testing. All the samples were tested at CMC, Vellore. 6892 samples were tested and 2759(40%) were positive for rotavirus antigen by Enzyme Immunoassay (EIA). Rotavirus genotypes (VP7 and VP4) were determined by hemi-nested multiplex PCR for 2732 EIA positive samples. G12 strains were detected in 10.5% (286/2732) of the genotyped samples. The proportion of G12 was 18.7% (179/955) in north India and 6% (107/1777) in south India. Overall, G12P[6] (137/286, 49.7%) and G12 P[8] (82/286, 28.6%) were the common circulating genotypes. In northern India, G12P[6] (60%, 107/179) was the most common genotype, followed by G12P[8] (15%). In contrast, G12P[8] (50%, 54/107) was the most common genotype in south India, followed by G12 P[6] (28%). G12P[11] (1 isolate each from the north and south India), and G12P[4] (2 strains from north India) were the other uncommon genotypes isolated. In conclusion, G12 rotavirus infection was more common in north India and there was a difference in circulating G12 strains between northern and southern parts of India.

969

VECTOR-HOST ASSOCIATIONS AND REASSORTMENT POTENTIAL OF TICK-BORNE ORBIVIRUSES

Anna C. Fagre, Nicholas Bergren, Rebekah C. Kading

Colorado State University, Fort Collins, CO, United States

Orbiviruses are segmented dsRNA viruses with a wide range of arthropod vectors and vertebrate hosts, including humans. Owing to the segmented nature of orbiviruses, species-level classification is often obfuscated. The International Committee on the Taxonomy of Viruses outlines a polythetic definition of orbivirus species, including but not limited to the reassortment of genome segments, conserved terminal nucleotide sequences, serological cross-reactions, comparison of homologous genome segments or proteins by sequence analysis, and host and vector ranges. With the advent and ubiquity of whole-genome sequencing, recent reports often rely solely on phylogenetic analysis of the conserved viral polymerase gene and other more variable segments. Bats have been identified as natural hosts for many high-profile zoonotic viruses. Four species of orbiviruses have been isolated from free-ranging bat species, two of which fall into the tick-borne orbivirus clade (Bukakata and Fomede). The viral polymerase genes of these viruses are genetically similar to one another and also to Chobar Gorge, an orbivirus isolated from a pool of ticks in Nepal. We have determined strong serologic cross-reactivity between polyclonal sera obtained from mice hyperimmunized with Chobar Gorge virus and both Bukakata and Fomede viruses. However, few studies have integrated whole genome sequencing and serology with *in vitro* segmental genetic reassortment potential. Ongoing work to further

define the species-level classification of this group of tick-borne orbiviruses includes pairwise co-infection of Bukakata, Fomede, and Chobar Gorge followed by serial passage on IDE8 cells (derived from *Ixodes scapularis*), Vero cells, and R06E cells (derived from *Rousettus aegyptiacus* bats). Plaque purification of isolates following serial passage will be analyzed for the occurrence of segmental reassortment utilizing RT-PCR and Sanger sequencing. Analysis of reassortment potential in cell lines derived from both the purported host and arthropod vector species will provide unique and valuable information to the study of orbivirus speciation.

970

SENSITIVITY OF A RAPID DIAGNOSTIC TEST FOR INFLUENZA

John Mark Velasco[1], Ma. Theresa Valderama[1], Ma. Theresa Alera[2], Paula Corazon Diones[1], Susie Leonardia[1], Cynthia Liao[3], Domingo Jr. Chua[3], Damon Ellison[4], Louis Macareo[4]

[1]PAVRU, Quezon City, Philippines, [2]PAVRU, Cebu City, Philippines, [3]VLMC, Quezon City, Philippines, [4]U.S. Army Medical Directorate-Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Influenza causes considerable morbidity and has significant operational impact in the military. Rapid influenza diagnostic tests (RDTs) which detect viral antigens of influenza are used as tools to screen patients with suspected influenza and are used to reduce inappropriate antibiotic use, decrease unnecessary diagnostic testing and to facilitate timely control measures prior to results of confirmatory tests during outbreaks or during field deployments where access to confirmatory tests is unavailable. Between Aug 2011 to Oct 2016, patients presenting with influenza-like illness (ILI) (n=2,333) at the V Luna Medical Center, Quezon City, Philippines were tested using Quickvue (QV) influenza A+B RDT and influenza real-time RT-PCR. Statistical tests of association were done to determine effect of age, viral titers (Ct values), and timing of collection on QV sensitivity/specificity to detect different influenza sub-types (Flu A/H3, Flu A/pdmH1, Flu A/H3+Flu A/pdmH1and Flu B). P value <0.05 was considered statistically significant. QV sensitivity, specificity, positive and negative predictive values can be seen in Table 1. Linear regression showed that QV sensitivity across all sub-types was significantly correlated with lower Ct values (higher virus titers) ($p<0.001$) and except for Flu A/H3 ($p=0.974$), was also significantly associated with timing of specimen collection ($p<0.05$). There were no statistically significant difference noted in QV sensitivity for Flu A/H3 ($p=0.130$), pandemic H1/N1 ($p=0.207$), Flu A/H3+pandemic H1/N1 ($p=0.341$), and Flu B ($p=0.103$) across different age groups but sensitivity of QV significantly differed ($p<0.001$) across the different influenza sub-types. The findings highlight the need to develop more sensitive influenza RDTs to detect circulating influenza strains.

971

SPATIAL AND TEMPORAL SPREAD OF ZIKA AND CHIKUNGUNYA VIRUSES IN COLOMBIA, A GRAVITY-MODEL BASED APPROACH

Kelly A. Charniga[1], Zulma M. Cucunubá[1], Marcela Mercado[2], Franklyn Prieto[2], Martha Ospina[2], Neil M. Ferguson[1], Pierre Nouvellet[3], Christl A. Donnelly[1]

[1]Imperial College London, London, United Kingdom, [2]National Institute of Health of Colombia, Bogota, Colombia, [3]University of Sussex, Brighton, United Kingdom

Zika virus (ZIKV) and chikungunya virus (CHIKV) were recently introduced into the Americas resulting in significant disease burdens. Understanding the spatial and temporal dynamics of the recent outbreaks in Colombia is key to informing control strategies at the subnational level. We have analyzed anonymized line lists data on 100,000 ZIKV and 380,000 CHIKV cases reported to SIVIGILA, Colombia's national public health surveillance system, between 2014 and 2017. These data include both suspected and laboratory confirmed cases. We fitted gravity models to analyze transmission between cities based on population size and distance, utilizing the approach of Eggo et al. in their study of the 1918 influenza pandemic. We were able to track the spread of reported cases between more than 300 locations (administrative level 2) on a weekly basis. We assessed the extent to which transmission depended on population density and then examined the effects of altitude, temperature, and annual precipitation on ZIKV and CHIKV spread. These environmental factors affect mosquito development and could help explain observed disease trends. Modeling at such fine spatial scale will inform both surveillance and control strategies.

972

ASSESSMENT OF POLIOVIRUS ANTIBODY SEROPREVALENCE IN HIGH RISK AREAS FOR VACCINE-DERIVED POLIOVIRUS TRANSMISSION IN MADAGASCAR

Richter Razafindratsimandresy[1], Jean-Michel Heraud[1], William Weldon[2], Steven Oberste[2], Ondrej Mach[3], Roland Sutter[3]

[1]Institut Pasteur de Madagascar, Antananarivo, Madagascar, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]World Health Organization, Geneva, Switzerland

Vaccine-derived polioviruses (VDPV) outbreaks typically occur in areas of low poliovirus immunity. Madagascar successfully eradicated wild poliovirus in 1997. However, multiple VDPV outbreaks have occurred since then, and numerous vaccination campaigns have been carried out to control the VDPV outbreaks. We conducted a survey of poliovirus neutralizing antibodies among Malagasy children to assess the performance of vaccination campaigns and to estimate the risk of future VDPV outbreaks. A random community survey was undertaken in children aged 6-11 months, 36-59 months and 5-14 years of age in four high-risk areas of Madagascar (Mahajanga, Toliara, Antsalova, and Midongy-atsimo) and in a reference area (Antananarivo). After obtaining informed consent, basic demographic and vaccination history, 2 mL of peripheral blood were collected. Neutralizing antibodies against all three poliovirus serotypes 1, 2, 3 (PV1, PV2, PV3 respectively) were detected by using a standard microneutralization assay. There were 1500 children enrolled and 1496 (>99%) provided sufficient quantity of blood for analysis. Seroprevalence for PV1 was >90% in all age groups and the study areas. PV2 seroprevalence ranged between 75-100% with the lowest found in the youngest age group in Midongy and Toliara. PV3 seroprevalence ranged between 79-100%. The seroprevalences in the reference area was not significantly different from that of high risk areas. Madagascar achieved high population immunity. In order to sustain the protection, routine immunization needs to be strengthened. Currently, the risk of new VDPV emergences in Madagascar appears low.

973

CLINICAL DEVELOPMENT OF VIRAL VECTORED VACCINES AGAINST MERS-COV

Katie Ewer[1], Pedro Folegatti[1], Duncan Bellamy[1], Catherine Mair[1], Naif Alharbi[2], Teresa Lambe[1], Danny Wright[1], George Warimwe[1], Sarah Gilbert[1]

[1]The Jenner Institute, University of Oxford, Oxford, United Kingdom, [2]King Abdullah International Medical Research Centre, Ministry of National Guard – Health Affairs, Riyadh, Saudi Arabia

Viral vectors have been used as delivery platforms for vaccines against several pathogens including malaria, HIV, TB, influenza, Ebola and hepatitis and have demonstrated acceptable reactogenicity in all age-groups including neonates, as well as excellent immunogenicity. Of seven vaccine candidates in clinical development against ebolavirus disease (EVD) during the recent West African outbreak, six were based on viral vectored technology with rVSV-ZEBOV demonstrating high, short-term efficacy against disease in a Phase III ring vaccination study in Guinea. Chimpanzee adenoviruses (ChAd) are attractive as viral vectors due to ease of genetic manipulation, compatibility with high-yielding GMP production processes, a safety profile suitable for administration to infants as young as 1-week of age and induction of potent cell-mediated immunity and neutralising

antibody responses. Building on these features, we are undertaking clinical development of a number of vaccines against important outbreak pathogens identified by the WHO Blueprint for R&D preparedness. Using ChAd vectors, the Jenner Institute is currently evaluating vaccine candidates against CCHF, EVD and Marburg, Lassa Fever and Nipah in pre-clinical models. Vaccines against MERS-CoV, Rift Valley Fever, Chikungunya and Zika will enter Phase I clinical trials during 2018 and early 2019. MERS-CoV is a zoonotic virus that causes respiratory infection and severe disease in humans with a fatality rate as high as 35%. Camels are the animal reservoir for the virus and hence a vaccine with utility in both dromedaries and humans would be of significant public health benefit. We will present safety and immunogenicity data from this Phase I, dose-escalation, first-in-man trial of ChAdOx1 MERS describing humoral and cellular immune responses from the study, which started in March 2018. A second Phase I trial will begin in Saudi Arabia in late 2018. This reinforces the utility of ChAd vectors as vaccines for outbreak pathogens because of the capability to rapidly produce GMP vaccine stockpiles for pandemic preparedness.

974

OXIDATIVE STRESS IN MALARIA ENDOTHELIAL PATHOLOGY

Marisol Zuniga, Ana Rodriguez

New York University School of Medicine, New York, NY, United States

Malaria remains a global burden worldwide, causing approximately 400,000 deaths annually. Blood stage malaria is characterized by a strong inflammatory response and also considered to be highly oxidative. Recent work in our laboratory indicates that oxidative stress could be an important driver of inflammation in malaria. In particular, we have found the host enzyme xanthine oxidase (XO) in combination with *Plasmodium falciparum*-infected erythrocytes induces a strong inflammatory response in human monocyte-derived macrophages. XO is an enzyme involved in purine catabolism, but is most noted for its ability to produce reactive oxygen species (ROS). XO has been shown to be elevated in African children with malaria and we have also found elevated activity of XO in adult Indian patients with uncomplicated or cerebral malaria. To further investigate the role of oxidative stress and disease pathology, precisely the role of XO in cerebral malaria, we studied the effects of XO alone on human brain microvascular endothelial cells (HBMECs). When we incubated HBMECs with XO, we observed a disruption in endothelial cell junctions. We will study the role of oxidative stress in cerebral malaria further by determining the effects of XO in combination with *P. falciparum*-infected erythrocytes on HBMECs and the signaling involved. Using mice models of malaria, we will also determine whether XO binds the endothelium during malaria infection, as described when this enzyme is in the circulation. Through these investigations we hope to obtain a better understanding of the interplay between oxidative stress and malaria endothelial pathology.

975

ASSESSMENT OF ARTEMISININ COMBINATION REPEATED TREATMENT EFFECT ON BLOOD CELL LINES PARAMETERS DURING A TWO-YEAR FOLLOW UP INVOLVING 3ACT, ARTESUNATE-PYRONARIDINE (PYR), DIHYDROARTEMININ-PIPERAQUINE (DHA-PQ) COMPARED TO ARTESUNATE-AMODIAQUINE (ASAQ) IN THE TREATMENT OF THE UNCOMPLICATED ACUTE *PLASMODIUM FALCIPARUM* MALARIA CASES IN BANFORA HEALTH DISTRICT

Issiaka Soulama, Maurice Ouattara, Noélie Henry, Aboubacar Sam Coulibaly, Moise T. Kaboré, Amidou Diarra, Daouda Ouattara, Edith C. Bougouma, Alphonse Ouedraogo, Amidou Ouedraogo, Benjamin Sombie, Issa N. Ouedraogo, Alfred B. Tiono, Sodiomon B. Sirima

Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso

Artemisinin combination therapies (ACTs) still remains in Sub Saharan Africa, the most effective anti-malarial drugs for the malaria treatment in areas with multidrug resistant *Plasmodium falciparum* malaria. The use of these drugs to treat malaria may be associated with possible side effects on the blood cells. It was therefore the aim of this study to undertake a comparative effect of a repeatedly administration of artesunate-amodiaquine, dihydroartemisinine-piperaquine, and artesunate-pyronaridine on haematological parameters (RBC count, Hb, WBC count, Platelets count) in *P. falciparum* uncomplicated malaria patients living in Burkina Faso. Confirmed malaria infected patients (n=763) aged from 6months to 54 years of both sexes were included in the study carried out in Banfora Health District area in Burkina Faso. About 2ml of blood sample was collected into EDTA tube from the same patient before the ACT administration and after at day 3, 7 and 28 of the follow up for blood cell lines analysis at each malaria episode. The findings of this present study show that Artesunate-Amodiaquine, Dihydroartemisinine-Piperaquine and Pyronaridine-Artesunate have effects on the hematological parameters in *P. falciparum* malaria infected patients. The three ACTs significantly reduced the proportion of abnormal blood levels of white blood cells, neutrophils, eosinophils and lymphocytes without significant effects on the proportion on the abnormal level of basophils cell. The proportion of abnormal blood level of RBC, hb and platelets were significantly increased at the day 3 after treatment before decreasing at day 28. However a repeatedly treatment of these three ACTs had no significantly effect on the blood cell level.

976

DEVELOPMENT OF RELIABLE MOSQUITO INFECTIONS WITH EAST AFRICAN *PLASMODIUM FALCIPARUM* STRAINS FOR HETEROLOGOUS CONTROLLED HUMAN MALARIA INFECTION

Kathryne D. Walker, Megan Dowler, Kathleen Moch, Hoseah Akala, Jorge O. Lopez, Norman C. Waters, Edwin Kamau, Lindsey S. Garver

Walter Reed Army Institute of Research, Silver Spring, MD, United States

Since 1985, the Walter Reed Army Institute of Research (WRAIR) has produced *P. falciparum*-infected mosquitoes for use in clinical trials to evaluate anti-malarial vaccines, drugs, and immunity. The vast majority of those &gt 110 experimental malaria challenges used Pf3D7 and its parent strain, PfNF54, but the recent progression of candidate anti-malarial products necessitates development of *P. falciparum* strains that are heterologous to Pf3D7. The standard methodology used to grow PfNF54 is insufficient to produce sporozoite infections with most other *P. falciparum* strains, therefore new methodology must be formulated to support heterologous strain production. In a multi-laboratory effort, the capabilities and resources of WRAIR and USAMRD-Kenya combine to form a *P. falciparum* development pipeline which has led to the advancement

of four new *P. falciparum* lines for use in Controlled Human Malaria Infections (CHMI) with over 30 additional lines still in various stages of progress. These lines were derived from parasitemic patient collections at hospitals or centers within the USAMRD-Kenya Surveillance Network and initially adapted to culture at USAMRD-K. Once received at WRAIR, strains were prioritized based on geographic diversity and CSP, MSP-1, and AMA1 sequence diversity, then individually optimized in two critical determinants of Pf mosquito infection: culture process and vector-parasite interactions. Strains initially propagated under PfNF54-like culture conditions were subjected to a suite of culturing protocol adjustments with assessment of gametocyte yield and exflagellation to measure progress. Strains with robust gametocyte yields were subjected to additional adjustments to the mosquito membrane feeding protocol and resulting infected mosquitoes were evaluated for oocyst and sporozoite burden. Using this workflow, we report 8 strains now produce sporozoites in anopheline mosquitoes; several produce infection levels similar to PfNF54. Over 25 additional Kenyan lines remain to be evaluated and this process is being extended to field isolated parasites collected by other DoD labs throughout the world.

977

EVALUATING LIFE CYCLE PROGRESSION OF *PLASMODIUM FALCIPARUM* USING IMAGING FLOW CYTOMETRY

Quentin D. Watson, Jürgen Bosch, Peter A. Zimmerman

Case Western Reserve University School of Medicine, Cleveland, OH, United States

Conventional flow cytometry (FC) has been used for evaluating a multitude of assays involving *Plasmodium falciparum* (Pf) red blood cell (RBC) infections. While FC allows characterization of Pf infected cells using fluorescent labeling (e.g., labeled antibodies for Pf-specific proteins), alone, this approach requires cell sorting to integrate image analysis for further assessment of parasite morphology and development. Imaging flow cytometry combines the power of fluorescence-labeling with visual inspection of individual cells. Using this technique, false-positive rate of a fluorescent signal can be minimized and higher resolution of probe localization achieved. Here, we studied erythrocyte invasion and development of the Pf transgenic strain, 3D7, expressing green fluorescent protein (GFP). Pf can be exposed to different perturbations (e.g., Cytochalasin D [CytoD], Heparin, and Phenylmethylsulfonyl fluoride [PMSF]). The underlying RBC invasion mechanism involves an actin-myosin motor termed "glideosome". CytoD inhibits actin polymerization and interferes with the glidosome, while PMSF, a serine protease inhibitor prevents the cleavage of the merozoite coat proteins through subtilisin-2 and thereby prevents a successful invasion. We hypothesized that CytoD and PMSF would strongly inhibit Pf RBC invasion based on our previous experiments. In addition, we hypothesized that Heparin would inhibit as well but to a lesser degree and the mode of action is unknown. By simply analyzing Hoechst positivity as a measure for infected cells, a surprising result was obtained with CytoD treatment. CytoD samples resulted in a significantly higher amount of parasites localized to the exterior of the RBC compared to the untreated sample, suggesting that parasites are trapped during their invasion step. These cells are marked as Hoechst positive although the parasite has not invaded the RBC and would not be able to maintain infectivity. The PMSF treated sample showed similar results, however with reduced parasite numbers (~85%). The remaining parasites seem to be trapped in late stages prevented from egressing the already infected RBC.

978

PLASMODIUM VIVAX CIRCUMSPOROZOITE PROTEIN (CSP) IS UNABLE TO FUNCTIONALLY COMPLEMENT *P. FALCIPARUM* CSP

Catherin Marin-Mogollon[1], Fiona van Pul[1], Shinya Miyasaki[1], Beatrice Winkel[1], Ahmed Salman[2], Jai Ramesar[1], Hans Kroeze[1], Syibli Othman[3], Takashi Imai[1], Meta Roestenberg[1], Chris J. Janse[1], Shahid M. Khan[1]

[1]LUMC, Leiden, Netherlands, [2]The Jenner Institute, University of Oxford, Oxford, United Kingdom, [3]Universiti Sultan Zainal Abidin, Terengganu, Malaysia

Rodent malaria parasites in which the endogenous gene encoding circumsporozoite protein (CSP) has been replaced with csp genes of human malaria parasites, *Plasmodium falciparum* (Pf) or *P. vivax* (Pv), are currently being used as pre-clinical evaluation tools to assess CSP vaccines *in vivo*. These chimeric rodent parasites produce fully infectious sporozoites in Anopheles stephensi mosquitoes that are capable of infecting rodent and human hepatocytes. Here we describe the creation, using CRISPR/Cas9 gene editing methodologies, and evaluation of two chimeric Pf parasites where the Pf csp gene has been replaced by two major Pv csp alleles, either the VK210 or VK247. The availability of fully infectious Pf-Pv CSP chimeric lines would open up possibilities to perform Controlled Human Infections to examine the potency of different Pv CSP vaccines in small scale clinical trials, and overcome several limitations that currently prevent the rapid evaluation Pv CSP vaccines in humans. The two chimeric Pf-Pv CSP lines have normal asexual and sexual blood stage development *in vitro* and A. stephensi mosquitoes fed with Pf-Pv CSP gametocytes produce sporozoite-containing oocysts. However, most oocysts degenerate before sporozoites are released from oocysts. In contrast, when we examine Pf parasites in which we have disrupted Pf csp, we find that oocysts are produced but sporulation is absent. By immunofluorescence analyses we demonstrate expression of Pv CSP in oocyst-derived sporozoites and that Pf CSP expression is absent. The absence of chimeric sporozoites in A. stephensi salivary glands demonstrates that Pv CSP can only partially complement Pf CSP and that species-specific features of CSP govern full maturation and development of sporozoites of these two human malaria parasites.

979

ME: HANDSOME MALARIA PARASITE. YOU: PUNCTUAL HOST THAT EXERCISES INFREQUENTLY AND LOVES DINNER. LET'S GET TOGETHER.

Aidan J. O'Donnell, Kimberley F. Prior, Nicholas J. Savill, Sarah E. Reece

University of Edinburgh, Edinburgh, United Kingdom

How biological rhythms influence the interactions between organisms is poorly understood. That parasites and hosts display rhythms in behaviours and immunity, suggests that rhythms are important in host-parasite interactions. These interactions matter for the outcome of infections, and understanding why they have evolved and how they're regulated could lead to innovative disease control measures. Malaria parasites have cyclic developmental rhythms that last multiples of 24-hours. The survival and transmission of malaria parasites is determined by whether their developmental rhythms are synchronised to the host's circadian rhythms, but how parasite and host rhythms interact to shape host health is poorly understood. We address this using rodent malaria (*Plasmodium chabaudi*) infections of wild type (WT) and arrhythmic clock mutant (Per1/2 double knock out) mice. We compare parasite and host rhythms in WT mice kept in LD and DD, with rhythms observed in mutant mice in DD. Second, we compare parasite and host rhythms in group- and singly-housed mice in DD. Finally, we use the mutant mice and a restricted feeding regime to decouple host rhythms in feeding from body temperature and locomotor activity and examine the consequences for parasite rhythms.

We show that: (i) parasites maintain normal rhythms in WT and mutant mice in DD, ruling out a circadian oscillator entrained by light; (ii) parasite rhythms match the phase of the host's feeding rhythm but not the phase of rhythms in activity or body temperature; (ii) parasite development in food-restricted mice is more synchronous than in ad-lib fed hosts; and (iv) mutant mice suffer no additional health costs of infection thus the intact clock in WT mice provides little obvious benefit in this disease model. We discuss how host feeding and social interactions could shape rhythms in parasite development and co-evolutionary trajectories between hosts and parasites.

980

VECTOR SPECIES SELECTION IS CRITICAL FOR OPTIMIZATION OF *PLASMODIUM FALCIPARUM* (7G8) INFECTION OF MOSQUITO SALIVARY GLANDS FOR CONTROLLED HUMAN MALARIA INFECTION

Tatyana Savransky[1], Ying Jin Clark[1], Kathryne Walker[1], Megan Dowler[1], Paul Howell[2], Jorge O. Lopez[1], Lindsey S. Garver[1]

[1]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States

Pf7G8 is a Brazilian strain of *Plasmodium falciparum* originally cloned from a patient sample at the Walter Reed Army Institute of Research over 25 years ago. Despite demonstrable mosquito infectiousness at that time, most attempts in the last decade to achieve robust Pf7G8 mosquito infections (oocysts and sporozoites) have been inconsistent and unreliable while the need to test pre-erythrocytic vaccines and drugs against *P. falciparum* strains that are heterologous to Pf3D7 has increased. Pf7G8 is an ideal heterologous parasite strain, given its genetic diversity, geographic origin, chloroquine resistance, and existing cryostocks prepared under GMP condition. However, to be useful for Controlled Human Malaria Infection (CHMI), strains must reliably produce robust infections on a precise timeline, which has been elusive for Pf7G8. Here, we report the reliability of Pf7G8 mosquito infections depends not only on growth conditions of the asexual stage culture but also on the mosquito vector species. Using parallel membrane feeding assays to evaluate the ability of three different Anopheles species to sustain CHMI-worthy sporozoite infections, we determined these species differentially give low, medium, and high infection rates, indicating the vector species is a primary determinate of Pf7G8 success. Using this optimized protocol, Pf7G8-infected mosquitoes were prepared for CHMI with oocyst and sporozoite infection prevalence and intensity equivalent to Pf3D7. Ongoing experiments are testing Pf7G8 as the second *P. falciparum* strain to produce oocysts and sporozoites in our cell-free continuous *in vitro* culture system.

981

ENDOTHELIAL GLYCOCALYX DEGRADATION IS ASSOCIATED WITH SEVERE DISEASE AND FATAL OUTCOME IN ADULTS WITH *PLASMODIUM FALCIPARUM* MALARIA

Nicholas M. Anstey

Menzies School of Health Research, Darwin, Australia

The pathogenesis of severe falciparum malaria is not fully understood. Microvascular sequestration of parasite erythrocytes and microvascular dysfunction/activation independently predict severity and outcome. The glycocalyx, a carbohydrate rich gel like layer lining the endothelium, is required for constitutive endothelial nitric oxide (NO) production and regulates endothelial activation and vascular permeability. We investigated the role of the glycocalyx loss in falciparum malaria pathogenesis. Inpatients (≥18 years old) with severe (SM, n=42) and moderately severe (MSM, n=56) falciparum malaria, and healthy controls (HCs, n=27) were enrolled at RSMM district hospital in Papua, Indonesia. Disease severity was assessed by WHO criteria. Glycocalyx degradation products (total glycosaminoglycans [GAG]) were measured on enrolment urine using a dimethylmethylene blue assay and normalised to creatinine. The GAG:creatinine ratio [GAG:Cr]) was related to disease severity and vascular NO bioavailability measured by reactive hyperemia peripheral arterial tonometry (RH-PAT). GAG:Cr was significantly higher in severe disease (mean 3.89; 95%CI 2.44-5.33) than in MSM (1.77; 1.26-2.28) and HCs (0.22; 0.06-0.39) p<0.001. In severe disease, GAG:Cr was higher in those with a fatal outcome (n=3; median 6.72, IQR 3.8-27.87) than in survivors (n=39; 3.1, 0.46-4.5) p=0.03. There was a significant association between parasite biomass (plasma HRP2) and GAG:Cr in MSM (r=0.48, p<0.001) and SM (r=0.47; p=0.002), and an inverse association between RH-PAT and GAG:Cr in SM (r=-0.4, p=0.007) and MSM (r=-0.27, p=0.05). The association between mortality and GAG:Cr remained significant after adjusting for parasite biomass (p=0.01) or lactate (p=0.02). The severity of endothelial glycocalyx breakdown is associated with impairment of endothelial NO, severe disease and a fatal outcome in adults with falciparum malaria. Glycocalyx degradation is likely to be a key process exacerbating endothelial NO deficiency, dysfunction and activation, parasite sequestration and disease severity, and predicts mortality in falciparum malaria.

982

A BACTERIAL COMPLEX IS REQUIRED FOR PLASTID INTEGRITY IN *PLASMODIUM FALCIPARUM*

Anat Florentin, Dylon R. Stephens, David W. Cobb, Jillian D. Fishburn, Manuel A. Fierro, Vasant Muralidharan

University of Georgia, Athens, GA, United States

The deadly malaria parasite, *Plasmodium falciparum*, contains a non-photosynthetic plastid known as the apicoplast, that functions to produce essential metabolites. Little is known about its biology or regulation, but drugs that target the apicoplast are clinically effective. Previous studies have identified several prokaryotic Clp (caseinolytic protease) genes, encoded by the *Plasmodium* genome. In bacteria, the evolutionary ancestors of the apicoplast, and in plants chloroplasts these proteins form complexes that degrade proteins in a proteasome-like manner to regulate key cellular processes, but their function in the apicoplast is completely unknown. Using phylogenetic analysis, we identified the Clp members that may form a regulated proteolytic complex in the apicoplast. We genetically targeted members of this complex and generated conditional mutants of the apicoplast-localized PfClpC chaperone, PfClpP protease and PfClpR inactive protease subunit. Conditional inhibition of the PfClpC chaperone resulted in growth arrest and apicoplast loss, and was rescued by addition of the essential apicoplast-derived metabolite, IPP. Moreover, cellular assays suggest that PfClpC inhibition interferes with the ability of the schizont stage parasites to divide and sort functional apicoplast organelles to daughter-merozoites. Using a double conditional-mutant parasite line, we discovered that the chaperone activity is required to stabilize the active protease, revealing functional interactions. Finally, bacterial Clp inhibitors were screened to test selective activity against *Plasmodium* Clp members. These data demonstrate the essential function of PfClpC in maintaining apicoplast integrity and its role in regulating the proteolytic activity of the Clp complex.

983

PLACENTAL MALARIA INDUCES OXIDATIVE STRESS IN HUMAN SYNCYTIOTROPHOBLAST

Demba Sarr, Jeffrey Ecker, David S. Peterson, **Julie M. Moore**

University of Georgia, Athens, GA, United States

Placental malaria is characterized by accumulation of *Plasmodium falciparum*-infected erythrocytes and maternal inflammation in the intervillous space of the placenta. These features, in particular the latter, are associated with placental damage and fetal compromise. However, understanding of the mechanisms that lead to poor pregnancy outcome and interventions targeting excessive host responses to placental malaria are still lacking. The syncytiotrophoblast, a cell of fetal origin, is known to

be responsive to malaria-infected erythrocytes as well as the malaria toxin, hemozoin, but its susceptibility to oxidative stress and how this might contribute to placental damage and dysfunction has not yet been directly investigated. The characteristics and key drivers of the syncytiotrophoblast response to oxidative stress were investigated using *ex vivo* human placental tissues and primary trophoblasts isolated from healthy pregnant women. Primary syncytiotrophoblast was exposed to hemozoin and tumor necrosis factor, a critical inflammatory cytokine, to model conditions found in pathogenic placental malaria. The data show remarkable lipid peroxidation in human placental samples from a malaria endemic setting and increased markers of an anti-oxidative response and oxidative damage in syncytiotrophoblast exposed to hemozoin, tumor necrosis factor, and tumor necrosis factor combined with hemozoin. These results suggest that oxidative stress may be a key driver of trophoblast functional compromise in placental malaria and could be targeted therapeutically to mitigate the poor outcomes associated with this syndrome.

984

LOW TO INEXISTENT KEY COMPONENTS OF NECROPTOSIS PROTECTS SYNCYTIOTROPHOLAST FROM DEATH RECEPTOR DEPENDENT PATHWAY OF NECROPTOTOSIS

Jeffrey Ecker, Demba Sarr, **Julie M. Moore**

University of Georgia, Athens, GA, United States

The syncytiotrophoblast is the main site of exchange of nutrients, waste products, gases, metabolites and drugs between the mother and the fetus. Efficient transfer of these products across the placenta is essential for healthy fetal growth and development. Dysfunction of the syncytiotrophoblast is implicated in poor birth outcomes in a number of syndromes, including placental malaria, but a complete understanding of the mechanisms by which this multinucleated cell is damaged and lost in the context of malaria is lacking. In particular, the susceptibility or resistance of the syncytiotrophoblast to necroptotic death is unknown. The objective of this study was to investigate how the syncytiotrophoblast reacts to necroptosis signals through death receptors, namely those detecting tumor necrosis factor, which has been linked to poor birth outcomes associated with placental malaria. Primary trophoblast and placental tissue explants were isolated from term healthy pregnancies and exposed to tumor necrosis factor and cyclohexemide after pretreatment with Z-VAD-fmk, a pan caspase inhibitor, conditions demonstrated to induce necroptosis in other epithelial cell types. Total proteins were isolated and subjected to western blot for the key components of the necroptosis and apoptosis pathways. A cell viability assay was used to assess cell death/viability on syncytialized primary trophoblast and immunofluorescence staining was used to localize proteins of interest. Results indicate that necroptosis through death receptor pathway is almost inexistent in primary trophoblast (cytotrophoblast and syncytiotrophoblast) as indicated by the very low expression of the receptor interacting protein kinase 3 and phosphorylated mixed lineage kinase domain-like, two key markers for necroptosis. In contrast, apoptosis was detected and confirmed by cell viability assay. These findings indicate that primary human trophoblast is resistant to necroptosis through death receptors and suggest that regulation of cell death pathways in syncytiotrophoblast is unique.

985

INVESTIGATING THE ROLE OF *PLASMODIUM VIVAX* DUFFY BINDING PROTEIN IN THE INVASION OF DUFFY NEGATIVE RETICULOCYTES IN THE PACIFIC COAST OF SOUTH AMERICA

Fabian E. Saenz[1], Andrés Núñez[1], Bibiana Salazar[1], Francis B. Ntumngia[2], John H. Adams[2]

[1]Centro de Investigación para la Salud en América Latina, Pontificia Universidad Católica del Ecuador, Quito, Ecuador, [2]Department of Global Health, College of Public Health, University of South Florida, Tampa, FL, United States

Ecuador is focusing in elimination of malaria; nevertheless, outbreaks and infections of the disease persist in the Coast and Amazon of the country. *Plasmodium vivax* is the most prevalent malaria parasite in Ecuador and it is endemic in the coast and Amazon regions. The invasion of reticulocytes has been considered dependent of the interaction of the *P. vivax* Duffy binding protein (PvDBP) in the merozoite of the parasite with the Duffy antigen receptor of chemokines (DARC) in the erythrocyte. Recently we reported that Duffy negative individuals were infected by *P. vivax* in northwest Ecuador and that Duffy negativity does not seem to provide protection against vivax infection in the northwest of the country. Consequently, we are investigating the role of PvDBP in this process. For this purpose, we have sequenced the binding region of *PvDBP* in 50 Ecuadorian *P. vivax* samples from the Amazon and Coast of the country in addition to determine the *PvDBP* copy number in Ecuadorian samples and we are in the process of studying the differential binding ability of DBP naturally found polymorphisms to DARC genotypes present in Ecuadorian individuals. Our results so far indicate that *PvdbpII* is highly diverse: 45 polymorphic sites were found, 35 sustitutions were non synonymous and 28 haplotypes were identified. There was a very high genetic variability for *Pvdbp RII* (Hd= 0.940 ± 0.019) while nucleotidic diversity was low (ϖ= 0.00736 ± 0,00059). Most haplotypes were unique for each locality. As expected, the Amazon region (where more cases are reported) was more diverse for *P. vivax* than the Coast (where a small number of infections are recorded). Even though the number of reported cases in Ecuador is low, there is important variability in merozoite invasion ligands. Nucleotidic diversity of *PvDBPII* may be involved in differential binding ability of PvDBP to DARC negative erythrocytes.

986

HOST ANEMIA INCREASES *PLASODIUM FALCIPARUM* GAMETOCYTOGENESIS *IN VITRO*

Morgan M. Goheen[1], Martha A. Clark[2], Rowena Neville[3], Fatou Joof[3], Andrew M. Prentice[3], Carla Cerami[3]

[1]University of North Carolina Chapel Hill School of Medicine, Chapel Hill, NC, United States, [2]Harvard School of Public Health, Cambridge, MA, United States, [3]MRC Unit The Gambia at the London School of Hygiene & Tropical Medicine, Fajara, Gambia

Gametocyte formation is essential for transmission of the malaria parasite. Several stress factors can contribute to increased levels of sexual conversion of the RBC stage of the parasite, including such conditions as sickle-cell trait. We thus hypothesized that asexual stage parasite growth attenuation in RBCs from anemic donors may additionally impact the rate and magnitude of gametocytogenesis. Clinical and epidemiological studies, as well as our *in vitro* modeling of asexual blood stage *Plasmodium falciparum* infection, have revealed iron deficiency and anemia are protective against malaria infection. Studying the impact of anemia on *P. falciparum* sexual reproduction can provide important insight into parasite transmission in populations where anemia is common - thus much of the malaria-endemic world. To study the impact of host anemia on gametocytogenesis, in this pilot study, we collected RBCs from 10 anemic and 10 non-anemic, otherwise healthy, Gambian children between the ages of 6 mo-3 years. We used these donor RBCs to quantify gametocyte production *in vitro* in relation to anemia status. Gametocyte detection was facilitated using a transgenic parasite strain expressing a GFP-tagged gametocyte specific protein, Pfs16. This allowed for flow cytometry-based high-throughput and more accurate detection of gametocyte formation, particularly at the early stages when gametocytes are difficult to distinguish from trophozoites by standard Giemsa-based microscopy. The gametocyte conversion rate was directly related to host hemoglobin and ferritin using linear regression modeling. Understanding the relationship between host anemia and malaria transmission, may guide public health strategies aimed at eliminating both. (This parasite strain was a kind gift from the laboratory of Dr. David Fidock.)

987

CRYOPRESERVATION OF *PLASMODIUM FALCIPARUM* GAMETOCYTES TO ENSURE VIABILITY AND INFECTIVITY TO MOSQUITOES

Rachel Evans, Abhai Tripathi, David J. Sullivan

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Malaria afflicts over 200 million people worldwide, with the most fatal infections caused by *Plasmodium falciparum*. Efforts to understand and reduce transmission often rely on the study of the gametocyte stage of the parasite. This stage, *in vitro*, requires extensive culturing for up to two weeks, which may be difficult in resource limited areas and impede the study of this transmissible stage. Cryopreservation of gametocytes would allow for more rapid culturing, and consequent infection of mosquitoes, to better study gametocyte biology and malaria transmission. Successful cryopreservation must maintain gametocyte viability, and previous cryopreservation studies have had limited success. In *Plasmodium falciparum,* traditional cryopreservation techniques lead to low gametocyte viability, and generally less than 5% of mosquitoes are infected upon standard membrane blood feeding assays (SMFA). All cryopreservation techniques to date are based off of a sodium chloride based protocol that has not been modified to our knowledge. We aim to develop an assay to effectively freeze gametocytes to maintain viability and infectivity to mosquitoes. Our preliminary data indicate that a novel modification of the traditional *P. falciparum* cryopreservation protocol leads to improved viability of gametocytes post-thaw. We have observed exflagellation for day 14/15 gametocytes after cryopreservation and thawing, though day 16/17 gametocytes appear to have reduced viability via this measure. Current studies aim to examine the infectivity of these frozen cultures in *Anopheles* mosquitoes via SMFA to determine the correlation of viability measured by exflagellation to infectivity in mosquitoes. We are also working to understand the optimal ratio of male to female gametocytes in cryopreserved cultures for infectivity to mosquitoes. We plan to freeze cultures at different development time points, with different ratios of male:female gametocytes, to understand how these subpopulations may influence success of infectivity. This study will help improve accessibility to gametocyte studies in a variety of lab settings.

988

THE EFFICACY OF ACTS IN KENYA; THE STATUS AT KWALE, KISUMU, BUSIA AND KISII COUNTIES' THERAPEUTIC EFFICACY STUDY SITES

Francis T. Kimani, Edwin K. Too, Eva K. Nambati, Maureen A. Otinga, William C. Kiarie, Kelvin K. Thiong'o, Moses M. Ngari, Charity W. Maingi, Patricia Njuguna

Kenya Medical Research Institute, Nairobi, Kenya

Artemisinin-based combination therapies (ACTs) and its derivatives are the most rapidly acting of all the current antimalarial drugs and recognition of their potential role as a component of combination therapy have led to several large trials aimed at assessing the efficacy of the different available drugs. This study was undertaken to evaluate the efficacy of fixed dose combinations, Artemether-lumefantrine and dihydroartemisinin-piperaquine in uncomplicated malaria patients in Kenya with an aim to inform malaria treatment policy and practice in the country. The study was a multi-site two arm blinded randomized clinical trial. In this are the outcomes of all the study sites evaluated for the efficacy of two artemisinin-based anti-malarial combination drugs, AL and DP, in four counties in Kenya. The *in-vivo* (clinical microscopy) treatment outcome was evaluated followed by molecular correction. Parasitological response at day 28 and 42, cure ratios in the two treatment arms, Fever Clearance Time (FCT), Asexual parasite clearance time (PCT), Gametocyte carrier rates and Adverse events were evaluated. A total of 352 children in Kwale, 315 in Kisumu, 334 in Busia and 314 in Kisii, aged between 6 months and 14 years were randomized and treated with either AL or DP . In this paper the uncorrected and corrected treatment outcomes at Day 28 and at day 42 in the Intention to treat (ITT) and the per protocol (PP) analysis populations are presented for each of the 4 sites, in different combinations and cumulatively. For Kwale and Kisumu combined, in the uncorrected Intention to treat (ITT) analysis, at day 42, 483 participants had ACPR, ACPR rate of 72%(95% CI 69-76%), 268 participants in arm A (ACPR rate of 77% (95% CI 72-81%)) and 215 in arm B (ACPR rate of 68% (95% CI 62-73%)); P-value 0.008. By day 28, participants with ACPR were 542, ACPR rate of 81% (95% CI 78-84%), 293 in arm A (ACPR rate of 84% (95% CI 80-88%)) and 249 in arm B (ACPR rate of 78% (73-82%)); P-value=0.06. In conclusion, the results from these study sites indicate a note worth trend of the ACT efficacy in the regions and calls for vigilance on the same for appropriate policy measures.

989

INCREASING *EX-VIVO* TOLERANCE OF GAMBIAN *PLASMODIUM FALCIPARUM* ISOLATES TO PARTNERS IN ARTEMISININ-BASED COMBINATION THERAPIES

Haddijatou Mbye

University of Ghana, Ghana; Medical Research Council Unit The Gambia @ London School of Hygiene & Tropical Medicine, Fajara, Gambia

Ex vivo drug susceptibility tests complement antimalarial efficacy studies by assessing the effect of individual components of antimalarial drugs on parasite survival. These can enable early detection of changes in parasite susceptibility to artemisinin-based combination therapies (ACTs) before the onset of clinical failure. This is crucial given the emergence of artemisinin-resistant *Plasmodium falciparum* in south-east Asia and the potential for spread into Africa. As National Malaria Control Programmes scale up efforts to control the disease, there is huge pressure on the parasites from exposure to antimalarials in the population and this could result in selection for resistant strains.We report on *ex-vivo* assays of samples collected from Gambian children with confirmed uncomplicated malaria over 4 transmission seasons; 50% inhibitory concentration (IC_{50}) (n=303; 2013-2015, 2017) and parasite survival assay (PSA) using 10 times the median IC_{50} (n=42; 2015), to determine *ex vivo* susceptibility to artemisinins and partner drugs. We also performed whole-genome sequencing of parasite isolates from 2008 to 2015 to determine candidate drug associated loci.*P. falciparum* isolates showed increasing tolerance to Lumefantrine over the 4 transmission seasons. The PSA results showed a substantial number of isolates with parasite growth and re-invasion following drug exposure. Additionally, whole genome sequencing of parasites showed temporal differentiation of SNPs on chromosome 7 undergoing directional selection, which had strong associations with increasing Lumefantrine tolerance.The data shows increasing tolerance and directional selection to Lumefantrine; a key component of the first-line ACT in The Gambia since 2008. Parasite survival following Lumefantrine exposure may be the effect of increased selection pressure from the temporal differentiation of SNPs on chromosome 7. Overall, parasite tolerance observed with both Dihydroartemisinin and Lumefantrine calls for robust and continuous surveillance for the efficacy of currently deployed ACTs.

990

TRENDS OF ANTIMALARIAL EFFICACY, MOLECULAR MARKERS OF DRUG RESISTANCE AND PARASITE POPULATION VARIATIONS AFTER MORE THAN A DECADE OF USING ARTEMISININ-BASED COMBINATION THERAPY IN MAINLAND TANZANIA

Deus S. Ishengoma[1], Celine I. Mandara[1], Marian Warsame[2], Marian Warsame[2], Marian Warsame[2], Michael Alifrangis[3]

[1]National Institute for Medical Research, Tanga, United Republic of Tanzania, [2]World Health Organization, Geneva, Switzerland, [3]University of Copenhagen, Copenhagen, Denmark

Following deployment of artemisinin-based combination therapies (ACTs) in most malaria endemic countries and the emergence and spread of resistance to artemisinins and partner drugs in South-East Asia (SEA), the World Health Organization (WHO) recommends regular therapeutic efficacy studies (TES) to monitor the performance of these drugs. This review assessed the trends of therapeutic efficacy of ACTs, molecular makers of artemisinins and partner drugs resistance (*K-13* and *Pfmdr1*), and parasite population variations after using ACTs for more than one decade in Tanzania. Data from published and unpublished TES and genetic studies of parasites and molecular markers antimalarial drug resistance were assembled and analysed. Efficacy data included TES of artemether-lumefantrine (AL), artesunate - amodiaquine (ASAQ), and dihydroartemisinin-piperaquine (DP); while data of *K-13*, *Pfmdr1* and other parasite genetic data were obtained from TES and cross-sectional surveys conducted in different parts of Tanzania from 2000 to 2017. Efficacy of AL was assessed in 14 studies and PCR corrected adequate clinical and parasitological response (ACPR) ranged from 95.1% to 100% between 2003 and 2017. Five studies tested ASAQ and ACPR increased from 88% to 100 in 2004 and 2017, respectively. Three studies assessed DP between 2014 and 2017, and the ACPR was 97 - 100%. Non-synonymous mutations in the *K-13* gene were <3% between 2006 and 2016 and none of these mutations have been associated with artemisinin resistance in SEA. For mutations in *Pfmdr1* associated with lumefantrine resistance, N86 was 6% - 10% between 2002 and 2006, but increased to 99.1% in 2016; and 184F increased from 6% in 2002 to 10% in 2006, and was 40 - 65% between 2011 and 2016. Analysis of spatial and temporal parasite population variations is being finalized and will be presented at the meeting. Although the ACTs are still efficacious with no known *K-13* mutations associated with artemisinin resistance, increasing *Pfmdr1* markers associated with lumefantrine resistance is a cause of concern and argue for continued surveillance for supporting TES and provide evidence-based teatmentt policies.

991

IMPACT OF HOST IRON DEFICIENCYON MALARIAL ARTEMISININ RESISTANCE

Fatou Joof[1], Morgan Goheen[2], Carla Cerami[1]

[1]Medical Research Council Gambia unit at London School of Hygiene & Tropical Medicine, Banjul, Gambia, [2]University of North Carolina, North Carolina, NC, United States

Iron deficiency anaemia has been shown to confer protection against malaria in endemic areas. Intracellular red blood cell iron concentrations may also have an effect on antimalarial drug (Artemisinin) activity. Artemisinin's activity relies on the cleavage of its endoperoxide structure and production of highly reactive free radicals. Iron deficient RBCs contain constitutively elevated levels of reactive oxygen species. This could create an environment high in oxidative stress that could potentially amplify the effect of artemisinin. Understanding whether iron deficiency impacts artemisinin activity is important as artemisinin is a first-line antimalarial in many areas where iron deficiency is common. For this pilot study, 11 anaemic and 18 non-anaemic children were recruited. Using *Plasmodium falciparum* strain MR4-1241 (originally from Cambodia and resistant to artemisinin) ring survival assay (RSA) was done using 700 nM dihydroartemisinin (DHA) to determine the different parasite survival rates between the anaemic and non-anaemic group. Conventional drug assays were also done to determine difference in Inhibitory concentration (IC_{50}) of DHA, Chloroquine (CQ), Lumefantrine (LUM) and Pyrimethamine (PYR). No significant differences in parasite survival were seen between the anaemic and non-anaemic group (median survival percentage= 2.2 and 2.5 respectively; p value =0.1 Mann Whitney's test). Furthermore, no significant difference (p value = 0.2, 0.1, 0.3) was seen in median IC50 between the two groups with the drugs DHA, CQ and LUM respectively. There was however a higher median IC50 value observed in the anaemic group for PYR (p value = 0.02). There is no difference in artemisinin activity, as measured by either the RSA or conventional IC50 assays, against *P. falciparum* parasites grown in RBCs from anaemic and non-anaemic RBCs. Additional work is needed to assess the impact of host iron status on lower concentrations of artemisinin.

992

COMPARING MALARIA TRANSMISSION IN TWO MALARIA STUDY SITES OF MALI

Fatoumata I. Ballo, Aminatou Kone, Diagassan Doumbia, Sekou Sissoko, Zana Lamissa Sanogo, Moussa M. Diallo, Ousmane Yossi, Adama Dao, Ogobara K. Doumbo, Abdoulaye Djimde

Malaria Research and Training Center, Bamako, Mali

Previous studies showed that malaria parasite clearance time following artesunate monotherapy was longer in Faladje than in Bougoula-Hameau. The objective of this study was to measure and compare malaria transmission in these two villages.The mosquitoes were caught using the catch spray method in 180 cases at each passage in Bougoula-Hameau and Faladje. Malaria vectors identified morphologically were treated with ELISA for determination of infection rate. *Anopheles gambiae s.l* was the only vector species of malaria found during our study in both villages. During the dry season, the density was 0.13 mosquitoe / hut in Bougoula vs. 0.02 in Faladje. No mosquito was infected in both villages. At the end of the rainy season, the density was 2.76 mosquitoes / case vs. 2.51. The aggressivity was 9 bites / person in Bougoula vs. 7.04 in Faladje The infection rate was 1.16% in Bougoula vs. 6.86 in Faladje, $p < 10^{-3}$. The entomological inoculation rate was 0.14 infective bite / person / month in Bougoula vs. 0.48 in Faladje. Parasite infection rate and entomological inoculation rates were both significantly higher in Faladje as compared to Bougoula-Hameau.

993

PHARMACOKINETIC PROPERTIES OF RECTAL ARTESUNATE IN AFRICAN CHILDREN WITH SEVERE MALARIA

Sue J. Lee

Mahidol-Oxford Tropical Medicine Reseach Unit, Bangkok, Thailand

Parenteral artesunate is the treatment of choice for severe *falciparum* malaria, but is still not provided in several malaria endemic areas. Many children with severe malaria die before or just after reaching a treatment facility capable of administering parenteral drugs. The rectal formulation of artesunate has been shown in very large community-based trials to reduce malaria mortality in children. But there is concern about artesunate toxicity as the absorption of rectal artesunate is erratic and the dose given is four times larger than the parenteral dose. This was a randomized, open labelled, 2-arm, cross-over, pharmacokinetic clinical trial in children admitted to hospital with severe malaria in the Democratic Republic of the Congo. Children received either 1 dose of rectal artesunate (10 mg/kg) followed 12 hours later by intravenous (IV) artesunate (2.4 mg/kg) (Arm 1) or vice versa (Arm 2). Artesunate (ARS) and dihydroartemisinin (DHA) concentration-time profiles were analysed using a standard non-compartmental approach. From Jul to Oct 2015, 82 children were enrolled. Twenty-seven children were malnourished (33%) and of those, 9 (11%) were severely malnourished. Children with 6 to 12.9 kg body weight

received, on average, 9.67 mg/kg (SD 2.05) of rectal ARS; those weighing 13 to 23.9 kg received 12.52 mg/kg (SD 1.98), and those between 24 to 34 kg received 10.79 mg /kg (SD 1.13). In the first 12 hours, T(max) and C(max) for both DHA and ARS was significantly higher in the IV group than in the rectal group. There was no significant difference in the total drug exposure (area under the concentration-time curve). Elimination half-life was significantly shorter in the IV group for both DHA and ARS. Of interest, the pattern of rectal absorption varied substantially between patients. The median estimated time for parasitaemia to decrease by half was 2.16 hours in Arm 1 (range 1.27 - 7.57) and 2.45 hours in Arm 2 (range 1.2 - 11.99, p=0.64). One patient in the arm that received rectal administration first died 10 hours after enrollment. Pre-referral artesunate should be given to any child suspected of having malaria who cannot reliably take oral medications.

994

EFFICACY OF ARTEMETHER-LUMEFANTRINE AND DIHYDROARTEMISININ-PIPERAQUINE FOR THE TREATMENT OF UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA AMONG CHILDREN IN WESTERN KENYA

Nelli Westercamp[1], Mary Owidhi[2], Kephas Otieno[2], Winnie Chebore[2], Ann M. Buff[3], Meghna Desai[1], Simon Kariuki[2], Aaron Samuels[1]

[1]Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Malaria Branch, Centre for Global Health Research, Kenyan Medical Research Institute, Kisumu, Kenya, [3]U.S. President's Malaria Initiative/Centers for Disease Control and Prevention, Nairobi, Kenya

Parasite resistance to antimalarials is a major threat for global malaria control. The World Health Organization (WHO) recommends monitoring local susceptibility patterns to inform national treatment guidelines by following a standard protocol for therapeutic efficacy studies carried out at regular intervals, with a change in recommended therapy considered if the polymerase chain reaction (PCR)-corrected treatment failure exceeds 10%. We evaluated the efficacy of the first-line antimalarial, artemether-lumefantrine (AL), and the second-line antimalarial, dihydroartemisinin-piperaquine (DP), for treating uncomplicated *Plasmodium falciparum* malaria in children 6-59 months old in western Kenya. From June 2016 to March 2017, children with *Plasmodium falciparum* mono-infection presenting to the outpatient clinic at Siaya County Referral Hospital, Bar Agulu and Mulaha dispensaries were enrolled in an *in-vivo* efficacy trial per WHO protocol. Children were randomized to treatment with a 3-day course of AL or DP and followed for 42 days.The main outcome was PCR-corrected adequate clinical and parasitological response (ACPR) rate measured at 28 days for AL and 42 days for DP after treatment initiation. A total of 340 children were enrolled in the study (166 in AL arm and 174 in DP arm). There were no early treatment failures in either arm, and all children cleared parasites by day 3. Based on per-protocol analysis limited to children with complete follow up, on day 28 PCR-uncorrected ACPR was 67% (91/135) in the AL arm and 95% (142/149) in the DP arm ($p<0.0001$). PCR-corrected ACPR at day 28 was 91% (95% CI: 85–95) in the AL arm and 99% (95% CI: 95–100) in the DP arm ($p<0.003$), and at day 42 it was 88% (95% CI: 81–92) in the AL arm and 94% (95% CI: 89–97) in the DP arm ($p=0.06$). Intention-to-treat analysis produced similar results. Both drugs were well tolerated. In summary, both AL and DP remain efficacious and well tolerated for treatment of uncomplicated malaria in western Kenya. The longer half-life of piperaquine relative to lumefantrine might provide a prophylactic effect, accounting for the lower reinfection rate in the first 28 days after treatment in the DP arm.

995

RATES OF SEVERE CUTANEOUS ADVERSE REACTION AMONG WOMEN TAKING SP-CONTAINING REGIMENS DURING PREGNANCY: A SYSTEMATIC REVIEW

Emily Reilly[1], Rewa Choudhary[1], Danielle Back[2], Monica Shah[3], **Julie R. Gutman**[3]

[1]Emory University School of Medicine, Atlanta, GA, United States, [2]Massachusetts General Hospital, Department of Medicine, Boston, MA, United States, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States

Malaria in pregnancy (MiP) is a preventable cause of maternal and infant morbidity and mortality; at least three doses of intermittent preventive treatment in pregnancy with sulfadoxine-pyrimethamine (IPTp-SP) are recommended to prevent poor outcomes. An estimated 30% of pregnant women in sub-Saharan Africa received adequate IPTp-SP in 2016. Severe cutaneous adverse reactions (SCARs), particularly Stevens-Johnsons Syndrome and Toxic Epidermal Necrolysis, can occur with use of SP. We performed a systematic review to update estimates of SCAR associated with IPTp-SP. Multiple databases were searched in accordance with PRISMA guidelines for systematic reviews. We included studies of IPTp-SP with adverse events (AEs) recorded. . The proportion of women with AEs was compared between those taking SP and non-SP containing IPTp regimens using Chi-squared test. Among 1,180 records identified from the search, data from 26 full-text articles published between 2001 and 2016 were included following assessment of title, abstract, and full-text eligibility. Among 67,572 women who had any SP-containing regimen (SP alone or in combination with piperaquine, azithromycin, or amodiaquine) there were no reported cases of severe rash, 347 hospitalizations (51.4 per 10,000), and 20 deaths (3.0 per 10,000). In the subset of studies with a non-SP containing arm, 12,575 women taking SP as compared to other regimens (N= 12,090) had higher rates of pruritus (171.8 vs 97.6 per 10,000, $p<0.01$) and lower rates of hospitalization (129.6 vs 210.9 per 10,000, $p<0.01$). Rates of death were not significantly different between the two groups (12.7 vs 17.4 per 10,000, $p=0.35$). There were no cases of severe rash. IPTp-SP was not associated with higher risk of SCAR or other severe AEs compared to the non-SP regimens. IPTp-SP remains an important tool to prevent adverse outcomes of MiP; our data highlight the safety of IPTp-SP. As malaria transmission declines, the risk-benefit ratio of IPTp-SP may shift. Continued monitoring of IPTp-SP efficacy and better estimates of incidence of drug related AEs will clarify the need to re-evaluate use of IPTp-SP in the future.

996

THE *EX VIVO* GROWTH PROFILE OF ARTEMISININ-RESISTANT PARASITES AFTER ARTESUNATE TREATMENT IN THE INDUCED BLOOD STAGE MALARIA MODEL

Maria Rebelo[1], Rebecca Pawliw[1], Jeremy Gower[1], Hayley Mitchell[1], Rebecca E. Watts[1], Louise Marquart[1], Jörg J. Möhrle[2], James S. McCarthy[1]

[1]QIMR Berghofer Medical Research Institute, Brisbane, Australia, [2]Medicines for Malaria Venture, Geneva, Switzerland

Artemisinin resistance was first detected by observing the effect of antimalarial drugs on parasite clearance in malaria patients. However, characterising artemisinin resistance in patients in the field is challenging for a number of reasons, including the confounding effect of human immunity on interpretation of parasite clearance. We recently established an artemisinin-resistant induced blood stage malaria (IBSM) model in which malaria-naïve subjects are inoculated with *Plasmodium falciparum* artemisinin-resistant parasites (K13; R539T). The aim of this study was to use samples from the novel artemisinin-resistant IBSM model to characterize the *ex vivo* growth profile of the K13 isolate. Subjects enrolled in a comparative randomized trial (ACTRN12617001394336) were inoculated with either ~2,800 viable K13 artemisinin-resistant parasites

(Day 0, n=7) or 3D7 artemisinin-sensitive parasites (Day 1, n=3). On Day 9 subjects received a single oral dose of artesunate (~2 mg/kg). Parasitemia was monitored by quantitative PCR targeting the *P. falciparum* 18S rRNA gene. Blood samples were collected pre-treatment and 2, 4, 8, 12, 16, 20, 24, 48 and 72 hours post-treatment from the two subjects from each group (K13, n=2; 3D7, n=2) who had the highest pre-treatment parasitemia. Samples were immediately cultured *ex vivo*. Parasite growth *ex vivo* was assessed by flow cytometry and microscopy for 20 days. In blood samples obtained 8 hours after treatment *ex vivo* parasite growth above 0.5% occurred earlier in K13 parasites (7-12 days post-incubation) than in 3D7 parasites (14-19 days post-incubation). Parasite multiplication rates during *ex vivo* growth and *in vivo* recrudescence will be compared to elucidate differences in drug response between artemisinin-resistant and artemisinin-sensitive parasites. Understanding the differences in recrudescence profiles between K13 and 3D7 parasites will provide greater insight into artemisinin-resistance.

997

CHROLOQUINE, SULPHADOXINE-PYRIMETHAMINE RESISTANCE MARKERS PREVALENCE IN AREAS OF EARLY ELIMINATION IN SELECTED PARTS WESTERN AND SOUTHERN ZAMBIA

Lungowe Sitali[1], James Chipeta[1], John M. Miller[2], Mulenga C. Mwenda[2], Daniel J. Bridges[2], Busiku Hamainza[3], Elizabeth K. Kawesha-Chizema[3], Moonga B. Hawela[3], Racheal F. Daniels[4], Bernt Lindtjørn[5]

[1]University of Zambia, Lusaka, Zambia, [2]PATH Malaria Control and Elimination Partnership in Africa (MACEPA), National Malaria Elimination Centre, Ministry of Health, Lusaka, Zambia, [3]National Malaria Elimination Center, Ministry of Health, Lusaka, Zambia, [4]Broad Institute of MIT and Harvard, Cambridge, MA, United States, [5]University of Bergen, Center of International Health, Bergen, Norway

One of the key factors in malaria infection management is having an effective drug to promptly treat malaria infections. Antimalarial resistance is one of the challenges in the fight against malaria and is a threat to achieving the malaria elimination goal. *Plasmodium falciparum* has developed resistance to most antimalarials due to drug pressure and other factors. This study sought to investigate the prevalence of Chloroquine and Sulphadoxine pyrimethamine(SP) molecular resistance markers in Southern Zambia. Data from a subset of individuals from a cross-sectional household survey, conducted during peak malaria transmission season in April and May 2017 was used. The survey collected socio-demographic information on households members,coverage of malaria interventions. In addition, malaria testing was done on all ages and dried blood spots were collected. Photo-induced Electronic Transfer - Polymerase Chain Reaction (PET-PCR) was used to analyse the filter papers for malaria species, the non-falciparum species will be excluded. High resolution melt (HRM) PCR will be used to analyse the resistant markers. Quintuple dhfr/dhps for SP and two PfCRT markers will be analysed. Samples from 1567 individuals were analyzed from the surveyed areas in Southern and Western provinces, of which304 were PET-PCR positive; and 266 were falciparum mono-infections. The results are not ready as analysis of the samples is currently under way. The findings will be available at the time of the conference. In conclusion,the results from the study will provide the national malaria program information on the current availability of resistance markers for chloroquine, ACTs and SP. While markers for resistance do not equate with clinical efficacy, these markers can be a sign that pressure for parasite selection is increasing and additional treatment options may need to be explored.

998

EFFICACY OF ARTEMETHER-LUMEFANTRINE FOR THE TREATMENT OF UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA IN NORTHWEST ETHIOPIA

Abebe Genetu Bayih[1], Aberham Abere[1], **Dylan R. Pillai**[2]

[1]University of Gondar, Gondar, Ethiopia, [2]University of Calgary, Calgary, AB, Canada

Artemether-lumefantrine (Coartem) is used for the treatment of uncomplicated falciparum malaria in Ethiopia. So far, treatment failure with artemisinin has not been observed in the country. Previously, we found a unique mutation in kelch 13 propeller domain (R622I) and anecdotal evidence for day-3 positivity by microscopy. In this study, we conducted a WHO 28-day efficacy trial to investigate the efficacy of artemether-lumefantrine (Coartem) for the treatment of uncomplicated *P. falciparum* malaria in Northwest Ethiopia (Negade Bahir and Dembia districts). We also assessed if co-infection with other parasites played a role in reducing the efficacy of antimalarial treatment. A total of 95 uncomplicated *P. falciparum* malaria patients were enrolled and completed the 28-day efficacy trial. We found out that artemether-lumefantrine is 100% efficacious with day-3 positivity detected by microscopy. We found that malaria patients were co-infected with other hemo- and intestinal parasites. Leishmania donovani, Schistosoma mansoni, and Ascaris lumbricoides were detected in 4.2%, 42.1%, and 6.3% of malaria-infected patients in this study, respectively. We conclude that artemether-lumefantrine is still efficacious in Northwest Ethiopia. Further studies will evaluate the presence of mutations in the kelch 13 gene, antibody levels to merozoite surface protein (msp), and the kinetics of parasite clearance using molecular amplification technologies.

999

MONITORING OF PHARMACOVIGILANCE DURING THE SEASONAL MALARIA CHEMOPREVENTION CAMPAIGN IN SENEGAL, 2013 TO 2017

Ibrahima Diallo, Mamadou L. Diouf, Mamadou L. Diouf, Moustapha Cisse, Alioune B. Gueye, Medoune Ndiop, Doudou Sene

Senegal National Malaria Control Program, Dakar Fann, Senegal

In 2012, Senegal National Malaria Control Program (NMCP) implemented seasonal malaria chemoprevention (SMC), an intervention recommended by the World Health Organization (WHO) in 2012 in areas of seasonal malaria in which at least 60 % of cases occur over a period of four months. In Senegal, SMC was implemented in a door to door campaign by community health volunteers administering a dose of sulfadoxine-pyrimethamine (SP) and amodiaquine (AQ) under directly observed therapy to children three months to ten years and leaving an additional two doses of AQ for the guardian to administer. In 2013, the campaign took place in four districts with almost 60,000 children in the target age group, and was accompanied by communications, advocacy, and social mobilization activities. While the drugs used in SMC are generally considered safe and effective, they can cause adverse events that may be minor, moderate, or in very rare cases, severe. During the SMC campaign, notices of adverse events were collected by the NMCP and processed by the Anti-Poison Center. In 2013, the treatments of SP+AQ administered to 59420 children under 10 years, 33 adverse events notifications were sent to the NMCP. In 2014, 290 adverse events notifications to 614785 children, in 2015, 2054 adverse events notifications to 620877 children, in 2016, 479 adverse events notifications to 644830 and in 2017, 117 adverse events notifications to 627067 children. Adverse effects reported were mostly minor: abdominal pain, nausea, vomiting, urticaria, etc. But in 2014, 02 severe adverse events were notified, in 2015, 03 severe adverse events and 2016, 02 severe adverse events. Most of the notifications were made by health post nurses. The Anti-Poison Center, which is responsible for determining imputability, judged that imputability was certain, possible,

improbable and uncategorized. In 2018, SMC will be implemented in 16 districts in the four regions of Kedougou, Tambacounda, Kolda and Sedhiou, targeting nearly 600,000 children. The pharmacovigilance system will be strengthened to ensure that adverse events will be notified and tracked.

1000

NATIONWIDE MOLECULAR SURVEILLANCE FOR *PFCRT, PFDHFR,* AND *PFDHPS* GENE MUTATIONS WITHIN THE HAITIAN *PLASMODIUM FALCIPARUM* POPULATION

Eric Rogier[1], Curtis Huber[1], Camelia Herman[1], Karen Hamre[1], Baby Pierre[2], Ruth Namuyinga[1], Kimberly Mace[1], Ventkatachalam Udhayakumar[1], Jean F. Lemoine[2], Michelle Chang[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Programme National de Contrôle de la Malaria, Ministère de la Santé Publique et de la Population (MSPP), Port-au-Prince, Haiti

Previous reports from the island nation of Haiti have indicated little evidence of resistance to chloroquine (CQ) based therapies in *Plasmodium falciparum*, and therefore CQ remains as a first line treatment for malaria, with sulphadoxine-pyrimethamine (SP) being second-line treatment. Therapeutic efficacy studies of CQ are impractical to implement in this low malaria prevalence setting, thus a molecular surveillance system was established in eleven health facilities throughout the country to monitor the emergence of genetic resistance markers for CQ and SP. In 2016 and 2017, 780 persons positive by malaria rapid diagnostic test were enrolled and patient samples assayed for putative resistance mutations to *Pfcrt, Pfdhfr,* and *Pfdhps*. Of these, 742/780 (95.0%) were found to contain *P. falciparum* DNA, and all specimens were found to be carrying *Pfcrt* wild-type allele CVMNK (codons 72-76). Sequencing for *Pfdhfr* found 257 (34.6%) of isolates harboring the S108N single mutation, as well as one isolate with the N59I and one with the C59R mutation. One isolate from the Ouest department was found to have triple *Pfdhfr* mutation (N51I, C59R, S108N). Sequencing *Pfdhps* in these isolates identified only one point mutation (A437G) in the Sud department. These results show and a predominant circulating wild-type *Pfdhps* genotype and no indication of emergence of *P. falciparum* CQ resistant *Pfcrt* alleles in Haiti. Though a significant percentage of *Pfdhfr* S108N genotypes were found, this alone has not been associated with SP resistance. This observation along with the evidence for lack of *Pfdhps* resistant markers (except in a single sample with a single mutation) suggests low SP resistance in Haiti. These data are consistent with the current recommendation of CQ and SP for treatment of malaria in Haiti. Nevertheless, continued annual molecular surveillance will be necessary to determine if and when resistant alleles emerge in the population.

1001

THERAPEUTIC EFFICACY OF ARTESUNATE-AMODIAQUINE AND ARTEMETHER-LUMEFANTRINE FOR THE TREATMENT OF UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA IN CHILDREN UNDER FIVE YEARS IN GUINEA

Abdoul Habib Beavogui[1], Alexandre Delamou[1], Aissata Fofana[2], Alioune Camara[3], Timothe Guilavogui[3], Samaly dos Santos Souza[4], Fassou Mathias Grovogui[1], Patrice Bouedouno[1], Abdoulaye Doumbouya[1], Julia Kelley[5], Eldin Talundzic[4], Abdoulaye Sarr[6], Mateusz M. Plucinski[7]

[1]Mafèrinyah Rural Health Research Center, Conakry, Guinea, [2]RTI International, Conakry, Guinea, [3]National Malaria Control Program, Conakry, Guinea, [4]Malaria Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States, [5]Atlanta Research and Education Foundation and Malaria Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States, [6]U.S. President's Malaria Initiative, Centers for Disease Control and Prevention, Conakry, Guinea, [7]Malaria Branch and U.S. President's Malaria Initiative, Centers for Disease Control and Prevention, Atlanta, GA, United States

Artemisinin-based combination therapy (ACT) is the first-line antimalarial treatment for uncomplicated *Plasmodium falciparum* infection in Guinea. This study prospectively evaluated the efficacy and tolerance of two ACTs used in the management of uncomplicated *P. falciparum* malaria cases in children under five years of age in two sites in Guinea. We conducted a two-arm, randomized therapeutic efficacy study evaluating artesunate-amodiaquine (ASAQ) and artemether-lumefantrine (AL) during a 28-day follow-up period. Data were collected at two health centers (located in Labé and Mafèrinyah Health Districts) between August 2015 and April 2016. Parasites from pre-treatment and day-of-failure samples from late treatment failures were genotyped and compared using neutral microsatellite markers to distinguish recrudescences from reinfections. A total of 421 subjects were enrolled, including 212 in the ASAQ arm and 209 in the AL arm; eight patients were lost to follow-up. Seven adverse events were reported, including two deaths that were not drug related. No patients had detectable parasitaemia on day 3. Of 22 late treatment failures, 20 were classified as reinfections and 2 as recrudescences. Across both sites, the therapeutic efficacy before molecular correction was 96% (95% confidence interval: 92-98%) for ASAQ and 93% (89-96%) for AL, and after molecular correction it reached 100% (96-100%) for ASAQ and 99% (97-100%) for AL. The two therapeutic combinations were effective for the treatment of uncomplicated *P. falciparum* malaria in children under five years in Guinea. Surveillance should continue to detect early antimalarial drug resistance in Guinea's fixed sentinel sites.

1002

PLASMODIUM MALARIAE- IF AT FIRST YOU DON'T SUCCEED, TEST, TEST AGAIN

Serena X. Zhang, Karl C. Kronmann, Michael J. Kavanaugh, James A. Blanks

NMCP, Portsmouth, VA, United States

Plasmodium malariae is widely distributed in Africa, South America, Southeast Asia and Oceana but causes less than 2% of malaria cases worldwide. However, the proportion of *P. malariae* cases reported in travelers is increasing, due in part to improved PCR based diagnosis. *P. malariae* often has low levels of parasitemia and poor sensitivity of both rapid antigen tests and light microscopy. Long incubation periods may also decrease clinical suspicion. We report a case of a male in his early thirties presenting 10 weeks after returning from central Africa with cyclical fevers, chills, and severe myalgia despite atovaquone/proguanil prophylaxis. He appeared ill with fevers to 103.1F, tachycardia to 121 beats/ minute but no focal findings. His labs were significant for leukopenia 2900 cells/uL, thrombocytopenia 82000 cells/uL, elevated aspartate aminotransferase 316 units/L and alanine aminotransferase 400 units/L. Due to his remote travel history and high level of suspicion, *P ovale* or *P malariae* infection were considered. The first three malaria smears and rapid tests were negative. However, a fourth test of rapid diagnostic antigen and light microscopy identified *P. malariae*. Although there are reports of breakthrough late onset fevers despite adherent atovaquone/proguanil prophylaxis, subsequent treatment has been paradoxically successful with the same medication. This case highlights increasing recognition of *P. malariae* infection despite long senescent periods, prior appropriate chemoprophylaxis, and tests with poor sensitivity. It also illustrates the importance to have high level of clinical suspicion as well as the question if this represents case of drug resistance versus an alternative mechanism of prophylactic efficacy.

1003

BALANCED IMPACTS OF FITNESS AND DRUG PRESSURE ON THE EVOLUTION OF *PFMDR1* ALLELES IN *PLASMODIUM FALCIPARUM*

Marvin Duvalsaint[1], David A. Fidock[2], Philip J. Rosenthal[1]

[1]University of California San Francisco, San Francisco, CA, United States, [2]Columbia University, New York, NY, United States

Antimalarial drug resistance may be balanced by loss of fitness in parasites with decreased drug sensitivity. We are interested in evaluating the relative fitness of *Plasmodium falciparum* containing resistance-mediating mutations with and without drug pressure. We therefore evaluated the impacts on *in vitro* fitness of two common mutations in the putative drug transporter *pfmdr1*, 86Y, which is associated with decreased sensitivity to chloroquine and increased sensitivity to lumefantrine, and 184Y, which has uncertain impacts on drug sensitivity. We co-cultured NF10 *P. falciparum* engineered for varied sequence at these two alleles and followed genotypes over time with and without drug pressure. Wild-type (WT) and mutant parasites with the *pfmdr1* 86Y and/or 184F mutant haplotypes were co-cultured 1:1 in competitive growth experiments over 60 days. The *pfmdr1* sequence was assessed every 4 days by pyrosequencing, allowing quantification of alleles. In the absence of drug pressure, N86 and Y184 parasites overgrew mutant parasites (after 60 days cultures contained ~76% WT N86 and >95% WT Y184, respectively). However, double mutant 86Y/184F parasites were not overgrown by WT (after 60 days cultures contained ~56 % WT). Culturing in the presence of 80 and 160 nM (¼ and ½ IC_{50}) chloroquine favored mutant parasites (~20% and 5% N86 after 60 days, respectively). Culturing in the presence of 0.5 and 1.0 nM (¼ and ½ IC_{50}) lumefantrine favored WT parasites (>95% N86 by day 24). Culturing in the presence of 9 nM (¼ IC_{50}) piperaquine favored mutant parasites (~30% N86 after 60 days). Our results and prior data suggest that the *pfmdr1* 86Y mutation engenders some cost in parasite fitness, but that the 184F mutation compensates for this fitness loss, affording growth of the double mutant equivalent to that of WT parasites. However, low level drug pressure favors genotypes with decreased sensitivity to the selecting drug. These findings highlight the interplay between drug pressure and fitness that is guiding the evolution of resistance-mediating *P. falciparum*. Studies of impacts of other resistance-mediating mutations are underway.

1004

CHARACTERIZATION OF PFCRT F145I IN PIPERAQUINE-RESISTANT *PLASMODIUM FALCIPARUM* ISOLATES FROM CAMBODIA THROUGH ZINC-FINGER NUCLEASE-MEDIATED GENE EDITING

Biraj Shrestha[1], Satish K. Dhingra[2], Matthew Adams[1], Kathy Strauss[1], Sudhaunshu Joshi[1], Leila S. Ross[2], Huy Rekol[3], Michele D. Spring[4], Mariusz Wojnarski[4], Mark M. Fukuda[4], David L. Saunders[4], Philip L. Smith[4], Chanthap Lon[4], David A. Fidock[2], Shannon Takala-Harrison[1]

[1]University of Maryland Baltimore, Baltimore, MD, United States, [2]Columbia University, New York, NY, United States, [3]National Center for Parasitology Entomology and Malaria Control, Phnom Penh, Cambodia, [4]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

The emergence of multidrug-resistant *Plasmodium falciparum* in Southeast Asia poses a threat to the control and elimination of malaria. We have previously shown that the *Plasmodium falciparum* chloroquine resistance transporter (PfCRT) F145I mutation is associated with reduced susceptibility to piperaquine, and confers resistance above that associated with amplified *plasmepsin II (pfpm2)* alone. In this study, we have used a gene editing approach to remove PfCRT F145I from Cambodian field isolates and have characterized the effect of this mutation on parasite susceptibility to piperaquine. Parasite isolates were collected as part of a survey of antimalarial drug resistance conducted in a region with significant clinical piperaquine resistance (Anlong Veng, Oddar Meanchey) in Cambodia. After adapting the isolates to *in vitro* culture, we genotyped them at the PfCRT F145I locus (via pyrosequencing) and estimated both *pfpm2* and *pfmdr1* copy number. All three isolates had multiple copies of *pfpm2* and the PfCRT F145I mutation but only one copy of *pfmdr1*. Using the piperaquine survival assay, the survival rate of the field isolates in all concentrations of piperaquine was greater than that of a piperaquine-sensitive lab strain (Dd2), and ranged from 25 to 60%, well above the 10% cutoff for piperaquine resistance. Transfection studies are underway and results will be presented.

1005

NOVEL QUANTITATIVE POINT-OF-CARE G6PD TEST FOR SAFE TREATMENT OF *PLASMODIUM VIVAX* MALARIA

Sevan Hrutkay, Maria Kahn, Pooja Bansil, Sampa Pal, Gonzalo J. Domingo

PATH, Seattle, WA, United States

Currently, primaquine is the only registered drug for the radical cure of *Plasmodium vivax, but* such 8-aminoquinoline class compounds present moderate to severe hemolytic risk in subjects with glucose-6-phosphate dehydrogenase (G6PD) deficiency. This risk represents a major barrier to wide-scale adoption of radical cure. To ensure the availability of an accurate and robust G6PD test and discriminate hemizygous-deficient males and heterozygous-intermediate females from normal, PATH has supported the development of the STANDARD G6PD Test by SD Biosensor. The test provides quantitative output of two analytes: G6PD enzymatic activity (U/g Hb) and hemoglobin concentration (g/dL) from single fresh whole blood specimen across a broad temperature-humidity range with a quick turnaround of two minutes. The STANDARD G6PD Test was evaluated at the PATH laboratory in two consecutive studies using 110 venous blood specimens and 100 paired venous and capillary specimens to determine the precision, accuracy, and linearity at ambient temperature and 32°C at 50% relative humidity, as per target product profile performance criteria. No statistical difference was observed between results generated at 22°C and 32°C, and the combined data sets had a correlation coefficient (R^2) value of 0.81 for G6PD and an R^2 value of 0.88 for hemoglobin against the reference assays. No bias was observed for either venous or capillary specimens. Furthermore, the STANDARD G6PD Test showed sensitivity and specificity of 100% (95% confidence interval [CI] 84-100%) and 99% (95% CI 97-100%) at 30% normal activity; 93% (95% CI 81-99%) and 90% (95% CI 85-95%) at 70% normal activity; and 86% (95% CI 75-94%) and 87% (95% CI 81-92%) at 80% normal activity. Next, the STANDARD G6PD Test will be evaluated in malaria-endemic regions to determine the World Health Organization prequalification dossier requirement and support the wider adoption of *P. vivax* radical cure.

1006

ASSESSMENT OF DRIED BLOOD SPOTS FOR IDENTIFYING MALARIA INFECTION BY MULTIPLEX ELISA

Ihn Kyung Jang, Sara Aranda, Rebecca Barney, Andrew Rashid, Smita Das, Eyad Helwany, Gonzalo J. Domingo

PATH, Seattle, WA, United States

Low-density malaria infections, which are common across a range of transmission settings, are poorly understood. A better understanding of these sub-microscopic infections in terms of antigenemia will inform development of a new generation of diagnostics that will greatly facilitate the eradication of malaria. An improved enzyme-linked immunosorbent assay (ELISA) test that enables quantification of low levels of multiple *Plasmodium* antigens in blood samples, including histidine-rich protein 2 (HRP2) and pan-specific lactate dehydrogenase (Pan LDH), was recently developed. Dried blood spot (DBS) is the most operationally feasible form of collecting blood samples in surveys in malaria-endemic settings. Here, we aimed to determine the feasibility of application of DBS analysis in the

monitoring of malaria infections. Methods for antigen elution from DBS and multiplex ELISA were optimized to achieve maximal elution efficiency and maximal sensitivity. Analytic performance of this assay was evaluated using matched blood and DBS samples prepared from *P. falciparum* culture strain and collected from the field studies. The results showed a correlation coefficient of 0.98 for HRP2 and Pan LDH. Using the polymerase chain reaction test as a reference, preliminary DBS analysis showed sensitivity of 85% and specificity of 100% for HRP2, and sensitivity of 95% and specificity of 100% for Pan LDH. This easy-to-use, less-expensive, high-throughput assay, combined with DBS, can be tremendously useful in mass screening for malaria infections.

1007

THE PERFORMANCE OF A HIGHLY SENSITIVE RAPID DIAGNOSTIC TEST COMPARED TO POLYMERASE CHAIN REACTION

Neil J. Saad[1], Caroline De Cramer[1], Lieven Vernaeve[1], William Etienne[2], Rekol Huy[3], Chea Nguon[3], Nimol Khim[4], Benoit Witkowski[4], Jean-Marie Kindermans[5], Martin De Smet[5]

[1]Médecins Sans Frontières, Preah Vihear, Cambodia, [2]Médecins Sans Frontières, Phnom Penh, Cambodia, [3]Centre for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, [4]Institut Pasteur du Cambodge, Phnom Penh, Cambodia, [5]Médecins Sans Frontières, Brussels, Belgium

Efforts to accelerate malaria elimination are limited by current diagnostic tools. Rapid diagnostic tests (RDT) are generally unable to detect parasitaemia below 50 parasites/µL (p/µL) while polymerase chain reaction (PCR) is often unavailable and doesn't allow for immediate treatment. Moreover, in a previous study we found that RDTs have a low sensitivity (18%, vs PCR) to detect low parasitaemia. However, recently a highly sensitive RDT (HSRDT), with claimed limit of detection 2-5 p/µL, was launched. Here, we present the first large-scale evaluation in field conditions; we evaluated the performance compared to PCR during pro-active case detection (ProACD) activities in Northern Cambodia from Oct 2017 - Mar 2018. ProACD entails the voluntary screening and treatment of asymptomatic at-risk individuals in 8 villages. Screening was done using the HSRDT (Alere Malaria Ag Pf) and PCR. HSRDT results were verified by a blinded double reading and the laboratory conducting the PCR was blinded to the HSRDT result. Moreover, for all PCR *Plasmodium falciparum* (Pf) + cases, the estimated parasitaemia was determined by PCR. We screened 2008 individuals, of which 38 were Pf+ using PCR (~2% prevalence). Of these, 13 were not detected using the HSRDT, resulting in a sensitivity of 66% (95% CI: 49-80%). Of the 1970 PCR negative results only two were HSRDT positive, giving a specificity of 99.9% (95% CI: 99.6-99.9%). During the double reading, only one was discordant, which was confirmed as positive by a third reader. The estimated parasitaemia was statistically significantly lower among the 13 false negatives (mean: 65 p/µL, SD: 128 p/ µL) compared to the 25 true positives (mean: 11366 p/µL, SD: 28213 p/µL), with 8 false negative individuals having a parasitaemia at/below the limit of detection (<2-5 p/µL). Further molecular analyses (HRP2 deletion and concentration) and comparison with standard RDT are currently ongoing. We show the feasibility of incorporating HSRDT in case finding strategies. The HSRDT has a high specificity, while the benefit of immediate treatment can be expected to compensate for the lower sensitivity.

1008

EVALUATION OF A NEW SEROLOGY RAPID DIAGNOSTIC TEST FOR IDENTIFYING INDIVIDUALS WITH RECENT *PLASMODIUM FALCIPARUM* INFECTION IN A UGANDAN COHORT

Odongo Bakar

Infectious Diseases Research Collaboration, Kampala, Uganda

Eliminating *Plasmodium falciparum* transmission is an increasing focus of anti-malaria efforts, and is now becoming feasible in countries throughout the world. As transmission reduces, prevalence of infection becomes heterogeneous, with *Foci* of persistent transmission within large populations with otherwise little or no transmission. With current tools, it is difficult to identify these populations and target resources appropriately since infection rates are low and infected people may be asymptomatic. A low-cost test is needed that can identify recently infected individuals with enough specificity to give assurance of the presence or absence of infection. To address this need, we developed a new serology-based rapid diagnostic test (RDT) capable of identifying individuals who have become parasite-positive within the past half year. The detection window is wide enough to enable reliable identification of transmission *Foci* without the need to test all individuals within a community, and short enough to reflect changing epidemiology patterns. The antigen in the assay is early transcribed membrane protein 5 (ETRAMP 5) that has previously been reported as a top predictor of recent *Pf* infection. To evaluate performance, we are currently testing the RDT in a longitudinal community-based study of malaria in Nagongera, Uganda (PRISM) that follows over 400 participants, aged 2-80 years and tests them every month for asymptomatic parasitemia using blood smears and quantitative PCR. To date, 158 samples have been tested from individuals where time since last parasite positive was known. Results show that the serology RDT is able to classify individuals with/without parasitemia in the past 180 days across a broad age range: < 5 years (n-43, 19/95% sens/spec), 5-15 years ((n=85, 25/97% sens/spec), > 15 years (n=30, 47/71% sens/spec), everyone (n=158, 25/93% sens/spec). We are awaiting the conclusion of enrollment to update results. This assay could also serve as a screening test for traveling individuals or are donating blood. It could also simplify the current WHO protocol for certification of national malaria elimination.

FIELD EVALUATION OF THE MALACHITE GREEN LOOP-MEDIATED ISOTHERMAL AMPLIFICATION AS A MALARIA DIAGNOSTIC IN A HEALTH POST IN RORAIMA STATE, BRAZIL

Heather M. Kudyba[1], Jaime Louzada[2], Karl A. Kudyba[1], Vasant Muralidharan[1], Joseli Oliveira-Ferreira[3]

[1]University of Georgia, Athens, GA, United States, [2]Federal University of Roraima, Roraima, Brazil, [3]Institute Oswaldo Cruz- Fiocruz, Rio De Janeiro, Brazil

Malaria is a debilitating parasitic disease that causes significant morbidity and mortality. Microscopic detection of parasites is currently the most widely used diagnostic, but this technique is limited in its ability to detect low-density infections and requires highly trained microscopists. More sensitive and user-friendly tools are needed to overcome these obstacles. We have shown previously that the molecular-based, colorimetric malachite green Loop-Mediated Isothermal Amplification (MG-LAMP) assay is an accurate tool for diagnosing malaria infection in a laboratory setting. In this study, we field evaluated this assay in a malaria diagnostic post in Roraima, Brazil. We prospectively collected 91 patient samples and performed microscopy, MG-LAMP, and real-time PCR (PET-PCR) to detect *Plasmodium* infection. Two independent readers were used to score the MG-LAMP tests to assess whether the sample waspositive (blue/green) or negative (clear). There was 100% agreement between the two readers (Kappa=1). Both the MG-LAMP and PET-PCR detected 6 and 7 more positive samples, respectively, than microscopy. The PET-PCR assay

detected 6 mixed infections (defined as infection with both *P. falciparum* and *P. vivax*) while microscopy detected only one and MG-LAMP detected two of these mixed infections. Microscopy did not detect any *Plasmodium* infection in 26 of the enrolled asymptomatic cases while MG-LAMP detected five and PET-PCR assay three positive cases. Overall, MG-LAMP provides a portable, user-friendly molecular method for malaria diagnosis and it is less subjective and more sensitive than microscopy. Importantly, MG-LAMP has the capacity to test at least 38 samples in one hour, allowing for the screening of large number of samples which is appealing when large scale studies are necessary e.g. in community surveillance studies. The current MG-LAMP assay was limited in its ability to detect mixed infection and extremely low density infections, but otherwise proved to be a powerful tool for diagnosing malaria in the field and opens news perspectives in the implementation of surveillance in malaria elimination campaigns.

A MALARIA MICROSCOPY QUALITY ASSURANCE SYSTEM IMPROVES DIAGNOSIS FOR MALARIA ELIMINATION IN MYANMAR

Soy Ty Kheang[1], Mie Mie Han[2], Thi Thi Htoon[3], Thiri San[4], Naung Naung[2], Zwe Thu Tun[2], Taylor Price[5], Neeraj Kak[5]

[1]University Research Co., LLC, Phnom Penh, Cambodia, [2]University Research Co., LLC, Yangon, Myanmar, [3]National Health Laboratory, Yangon, Myanmar, [4]National Malaria Control Program, Yangon, Myanmar, [5]University Research Co., LLC, Chevy Chase, MD, United States

Myanmar's goal is malaria elimination by 2030. To accomplish this goal, the National Malaria Control Program (NMCP), National Health Laboratory (NHL) and partners are committed to strengthening microscopy diagnosis in malaria endemic areas. The Asian Development Bank's (ADB) Regional Capacity Development Technical Assistance works to improve laboratory quality through strengthened quality assurance (QA) systems. Through this program, University Research Co., LLC (URC) developed malaria microscopy standard operating procedures (SOP) and a QA manual to improve laboratory technicians' skills and strengthen microscopy in health facilities in 10 townships in Mon State and Sagaing Region. The SOP and manual were approved by the Ministry of Health and Sports (MOHS) and microscopy trainings were conducted for 43 technicians (24: Mon State, 19: Sagaing Region) by experts from the NHL and NMCP in January 2018. The trainings are an intensive two-week course providing core training modules including theory of malaria microscopy and practical slide reading. In Mon State, technicians scoring <80% on the pre- and post-test significantly decreased from 42% to 4%. Similarly, in Sagaing Region, technicians scoring <80% on the pre- and post-test decreased from 63% to 5%. The project also supports necessary equipment, coaching, monitoring and supervision to all supported facilities. In addition, the NHL conducts panel testing for laboratory technicians to improve malaria microscopy skills. In 2016, one hospital in Mon State and two hospitals in Sagaing Region participated in panel testing, which emphasizes parasite identification, species, stages and density. Among the three hospitals, only one received an excellent score while the remaining two scored poorly. In February 2018, the NHL conducted panel testing for an additional 24 hospitals after the two-week training and resulting scores were excellent. To further institutionalize these improvements, the NHL and NMCP, with support of ADB's Health Strengthening Program should refine policy on the role of malaria microscopy and a QA system in the context of malaria elimination.

1011

DEVELOPMENT OF QUANTITATIVE PCR FOR ACCURATE QUANTIFICATION OF *PLASMODIUM* PARASITES USING NOVEL PRIMERS/PROBE FOR 18S RRNA GENES

Qiuying Cheng, Angela O. Achieng, Elizabeth M. Glenn, Prakasha Kempaiah, Douglas J. Perkins

University of New Mexico, Albuquerque, NM, United States

Malaria, a mosquito-borne infectious disease resulted in ~216 million cases and 445,000 global deaths in 2016. Malaria is caused by parasitic protozoans belonging to the *Plasmodium* genus. Since the clinical sequelae of malaria largely result from asexual blood stage parasites, accurate assessment of parasitemia is vital for patient management, epidemiological surveillance, and evaluation of candidate malaria vaccine efficacy. DNA-based *Plasmodium* 18S rRNA quantitative PCR (qPCR) is a *robust method* for quantifying *Plasmodium* parasites, particularly when parasite densities are below the limit of detection with traditional microscopy and/or undetected with rapid diagnostic tests. Among the five 18S rRNA alleles in the genome of *Plasmodium*, three alleles have over 99% sequence identity, whereas the other two have with high sequence homology with each other. We determined that the widely used primer pair (Plasmo1-F/Plasmo1-R) amplifies a region with del/ins, yielding amplicons of two sizes: 157 bp and 173 bp. In contrast, our novel primer pair (Plasmo2-F and Plasmo2-R) yielded only a single amplicon (130 bp), representing all five *Plasmodium* 18S rRNA alleles. Using this novel primer set with a probe within the amplicon, we were able to quantify single parasites in as little as 3.125 nL of *Pf*3D7 cultures at a parasitemia of 1%. These findings warrant further validation of the accuracy of the novel approach for quantifying malaria parasitemia in clinical isolates.

1012

FALSE-NEGATIVE RAPID DIAGNOSTIC TEST RESULTS DUE TO *PLASMODIUM FALCIPARUM* HISTIDINE-RICH PROTEIN 2/3-NEGATIVE PARASITES ARE UNCOMMON AMONG SYMPTOMATIC SUBJECTS IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Jonathan B. Parr[1], Fernandine Phanzu[2], Mansiangi Paul[3], Ekizo Kieto[2], Kashamuka Mwandagalirwa[3], Nono Mvuama[3], Joris L. Likwela[4], Steven R. Meshnick[1], Kyaw L. Thwai[1], Alison J. Poffley[1], Pomie Mungala[2], Eric M. Sompwe[5], Antoinette Tshefu[3], Adrien K. N'Siala[2], Albert N. Kalonji[2]

[1]University of North Carolina, Chapel Hill, NC, United States, [2]SANRU Asbl (Sante Rurale / Global Fund), Kinshasa, Democratic Republic of the Congo, [3]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, [4]DRC National Malaria Program, Kinshasa, Democratic Republic of the Congo, [5]DRC National Malaria Control Program, Kinshasa, Democratic Republic of the Congo

Reports of *Plasmodium falciparum* parasites with *pfhrp2* and/or *pfhrp3* (*pfhrp2/3)* gene deletions are beginning to emerge in sub-Saharan Africa. These deletions can make *Plasmodium falciparum* parasites undetectable by PfHRP2-based rapid diagnostic tests (RDTs). Current recommendations suggest transitioning from PfHRP2-based RDTs to less sensitive, less heat-stable alternative RDTs when the frequency of these parasites among subjects with symptomatic falciparum malaria exceeds 5%. We previously reported a 6.4% national prevalence of *pfhrp2*-negative *P. falciparum* infection among asymptomatic children enrolled in the 2013-14 Democratic Republic of the Congo (DRC) Demographic and Health Survey. In order to guide decisions about optimal malaria diagnostic testing policies in the DRC, we performed a follow-up, cross-sectional study of symptomatic malaria caused by *pfhrp2/3*-negative *P. falciparum.* We have now measured the prevalence of these parasites in 3,628 symptomatic patients in three provinces, including two found to have high prevalence (Kinshasa and South Kivu) and one with low prevalence (Bas Uele) during our initial survey. Subjects underwent malaria diagnostic

testing using microscopy and a PfHRP2-based RDT, and dried blood spot samples were collected for molecular testing. Among the 427 subjects with microscopy-positive, RDT-negative parasitemia, 60 were *P. falciparum* lactate dehydrogenase (*pfldh)* PCR-positive. We tested for *pfhrp2/3* deletions in 25 of these isolates and 73 microscopy-positive, RDT-positive, *pfldh* PCR-positive controls. Eight symptomatic infections due to *pfhrp2/3*-negative parasites were identified, with microscopy parasitemias ranging from 1,900 to 35,000 parasites/uL. Our initial findings suggest that false-negative RDTs due to *pfhrp2/3*-negative *P. falciparum* are uncommon among subjects with symptomatic malaria in the DRC, and additional analyses are underway. These findings support ongoing use of PfHRP2-based RDTs in the DRC.

CLINICAL APPLICATION OF MALARIAL RETINOPATHY DETECTION SYSTEM FOR HIGHLY SPECIFIC DIAGNOSIS OF CEREBRAL MALARIA

Vinayak Joshi[1], Jeffery Wigdahl[1], Sheila Nemeth[1], Gilberto Zamora[1], Peter Soliz[1], Susan Lewallen[2], Simon Harding[3], Benjamin Turner[3], Chatonda Manda[4], Terrie Taylor[5]

[1]VisionQuest Biomedical LLC, Albuquerque, NM, United States, [2]Kilimanjaro Center for Community Ophthalmology, Cape Town, South Africa, [3]University of Liverpool, Liverpool, United Kingdom, [4]University of Malawi, Blantyre, Malawi, [5]Michigan State University, East Lansing, MI, United States

Malarial retinopathy (MR) is a retinal manifestation of cerebral malaria (CM), a life-threatening clinical syndrome associated with malaria infection. The 2017 World Malaria Report estimates that malaria claimed the lives of 445,000 people worldwide, more than 75% of whom were African children under 5 years of age. Attributing mortality to CM on the basis of standard clinical features (depth of coma, the presence of parasitemia, absence of other obvious causes of coma) may misclassify up to 25% of deaths. If patients were found, on the basis of direct or indirect ophthalmoscopy, to have evidence of malarial retinopathy (MR), the specificity of the clinical diagnosis would exceed 90%. We have developed an artificial intelligence system, ASPIRE, for computer-based detection of MR that classifies patients as MR+ or MR-. The system integrates a fully automated retinal image analysis software with a portable retinal camera, Pictor-Plus. A clinical prototype was tested on the Pediatric Research Ward in the Queen Elizabeth Central Hospital (Blantyre, Malawi) in years 2017 and 2018. When compared with the ground truth (binocular indirect ophthalmoscopy), the specificity, sensitivity, and positive predictive value of ASPIRE for detecting MR were 100%, 62%, and 1.0, respectively. The clinical prototype received an encouraging feedback from the clinicians for its fully-automated functionality, portability, and user-friendly operability in the hands of a minimally -skilled user. In the next phase, we will redesign the system, improving the integration of the hardware/software components so that ASPIRE is affordable for clinical settings in Africa. Incorporating this technology into routine clinical care will improve the diagnosis of CM and will reduce the impact of disease burden in malaria-endemic areas.

SCREENING FOR ASYMPTOMATIC *PLASMODIUM FALCIPARUM* INFECTIONS IN MADAGASCAR: PERFORMANCE OF A HIGHLY-SENSITIVE RAPID DIAGNOSTIC TEST

Tojoniaina Herinjaka Andriamandimbisoa[1], Tovo Angelo Rakotomanga[1], Stéphane Rabearimanana[1], Noeline Rasoarimalala[1], Arinomenjanahary Malalanandrianina Rakotoarisoa[1], Laura Steinhardt[2], Omega Raobela[1], Thierry Franchard[1], Peter Zimmerman[3], Arsene Ratsimbasoa[1]

[1]National Malaria Control Program, Antananarivo, Madagascar, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Case Western Reserve University, Cleveland, OH, United States

Low-density malaria infections are common in endemic countries and can persist undetected by microscopy and conventional rapid diagnostic tests (RDTs). We evaluated the performance of a new highly-sensitive malaria RDT by comparing rapid test results with detection of *P. falciparum* by polymerase chain reaction (PCR) among asymptomatic individuals in Madagascar. In December 2017, an Alere™ Malaria Ag Pf Ultra Sensitive RDT (uRDT) was added to two ongoing malaria detection surveys in six sites across Madagascar. The first, in four districts in the south and west, included screening all children aged six to 13 years in public and selected private schools; the second included screening all residents > six months of age in two districts in central Madagascar. Socio-demographic and clinical characteristics of participants were collected using a structured questionnaire; participants with a temperature <37.5°C who did not report taking antimalarials in the previous month were considered asymptomatic. Blood samples were obtained by finger prick for RDT (SD Bioline Malaria Ag *Pf* / Pan), uRDT, and dried blood spot (DBS) for PCR. DNA extractions from 20% of randomly selected DBS were tested for *P. falciparum* by nested PCR. Sensitivity calculations were done using PCR as the gold standard. Of 2,566 asymptomatic participants, 498 with PCR results were analyzed. The median age of these participants was 11 years (range: six months-70 years) and 219 (44%) were male. A total of 35 (7.0%) were positive for *P. falciparum* by RDT, 45 (9.0%) by uRDT, and 39 (7.7%) by PCR. Of the 45 positive by uRDT, 32 (71.1%) were PCR positive; of the 35 positive by RDT 29 (82.9%) were PCR positive. The sensitivity of the uRDT for detecting *P. falciparum* infection was slightly higher than that of the RDT: 82.1% (95% CI: 66.0-91.5%) *vs.* 74.4%, (95% CI: 57.8-86.0%), p=0.205). Specificity of the uRDT (97.2%, 95% CI: 95.2 - 98.4%) was similar to that of the RDT (98.7 %, 95% CI: 97.1-99.4%), p = 0.948. The uRDT detected a greater number of asymptomatic *P. falciparum* infections compared with the conventional RDT and might be useful for asymptomatic screening-and-treatment campaigns in Madagascar.

1015

LONG-TERM QUANTITATIVE ANALYSIS OF HRP2 PERSISTENCE POST-ANTIMALARIAL TREATMENT IN SENEGAL

Magatte Ndiaye[1], Xavier Martianez Vendrell[2], Karen Anderson[3], Aminata Lam[1], Modou Diop[1], Marie Pierre Diouf[1], Isaac Manga[1], Qin Cheng[3], Alfredo Mayor[2], Babacar Faye[1], **Xavier C. Ding**[4]

[1]Service de Parasitologie, Faculté de Médecine, Université Cheikh Anta Diop, Dakar, Senegal, [2]Barcelona Institute for Global Health, Barcelona, Spain, [3]Drug Resistance and Diagnostics, Australian Defence Force Malaria and Infectious Disease Institute, Brisbane, Australia, [4]FIND, Geneva, Switzerland

The *Plasmodium falciparum* Histidine Rich Protein 2 (HRP2) antigen is highly expressed, secreted and tend to accumulate in the blood during infections. This facilitates its detection by rapid diagnostic tests (RDTs) even when most of the parasitized red blood cells sequester away from the peripheral blood. Yet, HRP2 persistence can lead to false positive RDT results, whereby the antigen detected is not indicative of a current infection but is merely the slowly eliminating residue from a past infection. Most studies published to date on the subject are qualitative only and none were conducted past 42 days of follow-up. To address

this limitation, we report here a detailed long-term quantitative analysis of HRP2 persistence post-antimalarial treatment in Senegal, together with an evaluation of the time-to-negativity for a conventional RDT (CO-RDT) and high sensitivity RDT (HS-RDT). A total 120 individuals with an uncomplicated *P. falciparum* mono-species infection confirmed by microscopy or RDT were recruited at two sites. A capillary blood sample was collected at baseline, every second day until day 6, and every 4 days until day 62 for HRP2 quantification by Luminex, for infection detection by PCR, CO-RDT, and HS-RDT, as well as for *pfhrp2* and *pfhrp3* genotyping. A total of 107 (89%) individuals completed follow-up and 96 (80%) were included for data analysis. The parasitemia geometric mean and the HRP2 median at baseline were 5.435 p/µL and 103.7 ng/mL [IQR: 13.5 - 661.3 ng/mL]. Nineteen individuals (19.8%) still had residual HRP2 levels detectable by Luminex at day 62 (1.1 ng/mL average concentration). Preliminary statistical analyses indicated a median HRP2 half-life of 1.0 day [IQR: 0.48 - 3.1] and a median assay positivity survival time of 18 days for a CO-RDT, 30 days for a HS-RDT, while all individuals turned negative by PCR no later than day 4. These results demonstrate the long-term persistence of HRP2 by providing quantitative measurements thereof up to day 62. Our data also provide the first evaluation of the impact of improved HRP2 sensitivity on the assay positivity lag-time post-treatment.

1016

MULTI-ANTIGEN PROFILES CAN CHARACTERIZE *PLASMODIUM FALCIPARUM* INFECTION STATUS AND PARASITE GENOMIC COPIES IN SAMPLES FROM ANGOLA, 2016

Mateusz Plucinski[1], Camelia Herman[2], Pedro Rafael Dimbu[3], Filomeno Fortes[3], Sean C. Murphy[4], Nahum T. Smith[4], Kurtis R. Cruz[4], Annette M. Seilie[4], Eric S. Halsey[1], Venkatachalam Udhayakumar[2], Michael Aidoo[2], Eric Rogier[2]

[1]Malaria Branch and U.S. President's Malaria Initiative, Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Malaria Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]National Malaria Control Program, Luanda, Angola, [4]University of Washington, Seattle, WA, United States

Surveys of *Plasmodium* infection in populations are key for planning and managing malaria control and prevention, allowing estimation of disease burden and assessing success of control and elimination programs. Traditionally, surveys have relied on rapid diagnostic tests (RDTs) and/or blood smear microscopy to determine malaria infection status at clinically-relevant parasite densities. However, RDTs do not provide information on parasite density, and high-quality microscopy is difficult to implement consistently for large surveys. Using 208 samples collected from outpatients attending 89 health facilities in Angola, we employed a bead-based immunoassay to detect and quantify the concentrations of three antigens: *P. falciparum* histidine-rich protein 2 (PfHRP2); pan-*Plasmodium* aldolase (pAldo); and pan-*Plasmodium* lactate dehydrogenase (pLDH). We also assayed the samples using ultra-sensitive qRT-PCR to detect and quantify *Plasmodium* 18S rRNA, from which we estimated a parasite density. For samples with no antigen detected, 16% (10/63) were positive for *P. falciparum* by qRT-PCR with a median parasite density amongst nucleic acid positive samples of 0.41parasites/uL. Of samples positive only for PfHRP2, 43% (43/100) were qRT-PCR positive with a median parasite density of 2.0p/uL. Of samples with the PfHRP2+/pAldo+/pLDH- profile, 96% (24/25) were qRT-PCR positive, and the median parasite density was 208p/uL. Samples positive for all three antigens were all qRT-PCR positive (100%, 20/20), with a median parasite density of 3,104p/uL. Concentrations of PfHRP2 (R^2 = 0.56), pAldo (R^2 = 0.64) and pLDH (R^2 = 0.64) increased linearly with increasing qRT-PCR-estimated parasite density. The multi-antigen profile predicted presence and amount of *P. falciparum* nucleic acids, suggesting the spectrum of the different kinds of parasite carriage in a population could potentially be characterized in an inexpensive and high-throughput manner simply by categorizing infections by multi-antigen profile. Determination of multi-antigen profile in additional populations and settings will provide data for assessing the method's utility.

1017

RAPID DIAGNOSTIC TESTS FOR MALARIA - SEVEN YEAR RESULTS FROM A PROFICIENCY TESTING SCHEME RUN BY UK NEQAS

Jaya Shrivastava, Agatha C. Saez, Selvarani Muruguppillai, Peter L. Chiodini

Public Health England, London, United Kingdom

Rapid Diagnostic Tests (RDTs) have become increasingly popular in the laboratory diagnosis of malaria because they are low technology, require less expertise than blood film examination and performing the test is faster than making, staining and examining blood films. Since RDTs are being used more frequently in clinical laboratories particularly by on-call personnel and as UK NEQAS aims to ensure that participants have access to specimens that are relevant to their current laboratory practice, UK NEQAS Parasitology established an ISO 17043-2010 accredited Scheme for RDTs for malaria. We present findings from the first 7 years' performance of participants. The overall performance for specimens to date is good with a mean of 91% correct results from participants. On an average 4% of participants reported false negative results for specimens containing *Plasmodium* antigens and 2% reported false positive results for specimens containing no malaria antigens. More false negative results were reported when non-*P. falciparum* antigens (11%) were present than when *P. falciparum* antigens (1.6%) were present. The scheme has highlighted problems with the reporting of false positive and false negative results particularly in the detection of non-*P. falciparum* species. We discuss whether these problems could be kit related or operator related. Furthermore, to reduce the chance of antigen degradation potentially encountered by the EQA samples during transit to the participating laboratories, the UK NEQAS team investigated the feasibility of using freeze dried blood as sample matrix. Results of those analyses will also be presented here and will illustrate that freeze dried blood is a suitable matrix as the performance of freeze dried blood is at par with liquid blood with respect to performance at various parasitaemia levels, identifying different malaria species and suitability of use with various RDT kits.

1018

EVALUATION OF THE PERFORMANCE OF ULTRA-SENSITIVE RDT COMPARED TO CONVENTIONAL RDT AND ULTRA-SENSITIVE QPCR FOR THE DIAGNOSIS OF MALARIA

Natalie E. Hofmann[1], Clara Antunes Moniz[1], Aurel Holzschuh[1], Kristina Keitel[1], Frank Kagoro[2], Josephine Samaka[3], Noémie Boillat[4], Iveth González[5], Blaise Genton[1], Valérie D'Acremont[1], **Ingrid Felger**[1]

[1]Swiss Tropical and Public Health Institute, Basel, Switzerland, [2]Ifakara Health Institute, Dar Es Salaam, United Republic of Tanzania, [3]Amana Hospital, Dar es Salaam, United Republic of Tanzania, [4]University Hospital, Lausanne, Switzerland, [5]Foundation for Innovative New Diagnostics, Geneva, Switzerland

An ultra-sensitive malaria rapid diagnostic test (us-RDT) for the detection of low malaria parasite densities in the field was recently developed, but its usefulness to aid in elimination efforts is disputed. The diagnostic performance of us-RDT was evaluated against conventional RDT (conv-RDT) and ultra-sensitive qPCR (us-qPCR, sensitivity: 0.1 parasites/µl [p/µl]) in 3004 Tanzanian children (age 2-59 months) and 515 adults (age 18-80 years) presenting with fever (≥37.5 °C) to outpatient clinics. Venous blood samples were retrospectively examined with these different diagnostics. For us-qPCR, infections with parasite densities below 10 p/µl were scored positive only if detected in two replicate DNA extracts. conv-RDT detected *P. falciparum* in 232/3004 children (8%) and 35/515 adults (7%). us-RDT detected an additional 10 children (0.3%) and 2 adults (0.4%). us-qPCR

detected an additional 81 children (3%) and 11 adults (2%). Diagnostic sensitivity of conv-RDT and us-RDT against us-qPCR was 73% and 74%. Diagnostic specificity of both RDTs was above 99%. Half of us-RDT positive/conv-RDT negative samples (6/12) were also us-qPCR negative. Geometric mean parasite densities by us-qPCR were higher in children compared to adults (3'108 p/µl vs 1'101 p/µl). Particularly in children, the distribution of parasite densities was skewed towards high densities (children: median 45'132 p/µl, interquartile range [IQR] 12-376'759 p/µl; adults: median 1781 p/µl, IQR 27-8'7812 p/µl). Both, conv-RDT and us-RDT, detected practically all infections with densities above 100 p/µl (conv-RDT: 98% positive, 236/242; us-RDT: 98%, 237/242). In infections with densities below 100 p/µl the proportion of RDT-detectable infections increased from 19% (25/130) using conv-RDT to 23% (30/130) using us-RDT. In conclusion, the majority of *P. falciparum* infections in febrile children and adults are readily detectable by conv-RDT and the gain achievable by applying us-RDT is low. Additional us-RDT positive results may represent residual circulating antigen rather than active PCR-detectable *Plasmodium falciparum* infections.

DIAGNOSTIC PERFORMANCE OF THE XN-30 HEMATOLOGY ANALYZER FOR DETECTION OF *PLASMODIUM* PARASITEMIA IS COMPARABLE TO BLOODSMEAR MICROSCOPY: VALIDATION FROM A FIELD STUDY IN NANORO, BURKINA FASO

Annelies Post[1], Berenger Kabore[1], Joel Bognini[2], Salou Diallo[2], Palpouguini Lompo[2], Basile Kam[2], Natacha Herssens[3], Isaie J. Reuling[1], Wouter van der Heijden[1], Kjerstin Lanke[1], Teun Bousema[1], Robert W. Sauerwein[1], Halidou Tinto[4], Jan Jacobs[3], Quirijn de Mast[1], Andre J. van der Ven[1]

[1]Radboud University Medical Centre, Nijmegen, Netherlands, [2]Clinical Research Unit of Nanoro/Insitute of Health Sciences, Nanoro, Burkina Faso, [3]Institute of Tropical Medicine, Antwerp, Belgium, [4]Polytechnic University of Bobo-Dioulasso, Bobo-Dioulasso, Burkina Faso

There is a lack of easy-to-use, affordable and accurate diagnostic tools that directly detect *Plasmodium* in endemic areas. We previously demonstrated that the novel Sysmex hematology analyzer (XN-30) can reliably detect and quantify parasitized erythrocytes in-vitro and in a controlled human malaria infection trial by using blue laser technology and flow cytometry (Limit of Detection 20 parasites(p)/µl). Next, a phase-3 diagnostic trial was performed at the district hospital of Nanoro between March 2016 - July 2017, to validate the XN-30 for detection of *Plasmodium* parasitemia in a malaria endemic setting. Patients with acute febrile illness aged > 3 months were included. XN-30 and thick bloodsmear microscopy (BS) were performed at inclusion. *Plasmodium* qPCR was performed in batch on stored whole-blood after trial conclusion. Researchers were blinded until all results were obtained. BS was used as reference standard, XN-30 results were also compared to qPCR. In total 916 patients were included. *Plasmodium* was detected in BS in 244 cases: n=229 *P. falciparum*, one *P. malariae*, two *P. ovale* and 12 mixed infections. Parasite density ranged from 24 - 491,802 p/µl (IQR 745 - 77,055). Compared to BS, sensitivity and specificity of XN-30 was 98.8% and 99.0% respectively, with positive- and negative predictive value of 97.9% and 99.4% (AUC 0.99). An additional 165 cases were detected by qPCR, 20 with parasitemia of >10 p/µl. XN-30 detected *Plasmodium* in 30 cases missed by BS. Three BS positive cases were missed by XN-30, two with low parasite density (<20 p/µl in PCR) and one with high parasite density. The latter was most likely a sample mix-up. Correlation in parasite density between smear and XN-30 was 0.81. Costs of XN-30 will be comparable to rapid diagnostic tests. In conclusion, the diagnostic performance of XN-30 to detect *Plasmodium* parasitemia in a malaria endemic setting is comparable to BS but with higher sensitivity to low parasite densities. Hematology analyzers are used globally. Implementation of the XN-30 in malaria endemic areas will provide basic hemocytometry data as well as an effective and affordable tool to detect and follow-up malaria.

PLATFORM FOR PROSPECTIVE MULTIPLEX SEROSURVEILLANCE MONITORING ESTABLISHED IN SENEGAL

Aida S. Badiane[1], Eric Rogier[2], Udhayakumar Venkatachalam[2], Mamadou A. Diallo[1], Khadim Diongue[1], Katharine Sturm-Ramirez[3], Alioune B. Gueye[4], Fatou B. Fall[4], Medoune Ndiop[4], Doudou Sene[4], Julie I. Thwing[2], Daouda Ndiaye[1]

[1]Universite Cheikh Anta Diop, Dakar, Senegal, [2]Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, and US President's Malaria Initiative, Dakar, Senegal, [4]Senegal National Malaria Control Program, Dakar, Senegal

Malaria control interventions have resulted in a dramatic decline in malaria In Senegal during the past decade, with parasite prevalence declining from 6% in 2008 to less than 1% in 2016 in nationwide surveys. However, reported incidence has not declined appreciably since the roll out of rapid diagnostic tests (RDTs) in 2008 (26 per 1000 residents in both 2010 and 2017), as data completeness, care seeking, and testing rates improved. Given the low parasite prevalence and challenges interpreting health facility surveillance data, other methods are needed to monitor changes in malaria transmission. In 2017, the National Malaria Control Program began collection of dried blood spots on filter paper from patients aged 0-19 years seeking care for febrile illness (and who thus received an RDT) at 24 malaria sentinel sites throughout Senegal. Multiplex serology was used to measure prevalence of long half-life (MSP1) IgG antibodies to all four species of human malaria, as well as short half-life (LSA1) IgG against *P. falciparum,* from 1380 samples collected October 2017 to January 2018. Detection of antibody to vaccine preventable pathogens, relevant parasitic pathogens, and other pathogens of public health interest (dengue) was also performed. RDT positivity in febrile patients nationwide was 9%, ranging from 1% in the low transmission north to 34% in the southeast, and ranging from 5% among children < 5 years to 13% among children 15-19 years. Seroprevalence of antibodies to PfMSP1 was 28% nationwide, ranging from 15% among children under 5 years to 46% among children 15-19 years, and ranging from 18% in the north to 60% in the moderate transmission southeast. Analysis of other antibodies is ongoing. Seroprevalence of antibodies to *Plasmodium falciparum* may provide more information to measure changes in malaria transmission than currently used methodologies. While not nationally representative, this serosurveillance platform, built on a network of sentinel sites from which epidemiological data have been collected for many years, will allow the Ministry of Health to prospectively monitor seroprevalence of antibodies to pathogens of interest.

MAKING THE CASE FOR REGIONALLY TAILORED MALARIA CONTROL INTERVENTIONS ACROSS THE DIVERSE ISLAND OF MADAGASCAR

Rosalind E. Howes[1], Peter W. Gething[1], Peter A. Zimmerman[2], Arsene Ratsimbasoa[3]

[1]University of Oxford, Oxford, United Kingdom, [2]Case Western Reserve University, Cleveland, OH, United States, [3]National Malaria Control Programme of Madagascar, Antananarivo, Madagascar

Malaria remains a major burden in Madagascar despite decades of control efforts. Reflecting the island's ecology, malaria epidemiology is highly diverse, encompassing all phases of the control spectrum. Major disparities exist in access to healthcare, frequently impeded by neglected infrastructure. This overall heterogeneity is not sufficiently reflected in current National Malaria Control Programme (NMCP) policy, which remains rooted to a sub-national stratification from the 1990s with policy mainly driven by a dichotomous divide between "high" and

"low" transmission districts. Through collaboration with the NMCP, we have developed an updated stratification reflecting current transmission patterns, and conducted an analysis of routine case data to characterise the sub-national epidemiology according to the new stratification. Complementary to this, high resolution malaria prevalence maps were derived from nationally representative Malaria Indicator Survey datasets to allow quantitative assessments of spatio-temporal trends in infection prevalence, a dataset independent of the biases associated with routinely reported clinical case data. Results from these two analyses indicated recent resurgences in transmission, with prevalence more than doubling between 2011 and 2016 in all parts of the country. High resolution spatio-temporal epidemiological analyses can help identify vulnerable regions and populations, supporting efforts to tailor control interventions to local needs. Public health in Madagascar remains precarious, largely externally funded. Nevertheless, the country has stated its objective for malaria pre-elimination status by 2022. The path to elimination differs across the country, driven by complex constellations of factors far more complex than current disease incidence levels which are commonly relied on exclusively. The different threads of this collaboration between the NMCP implementers and the geospatial modelling combine to support epidemiological analyses and policy-setting, with a priority placed on the need for targeted high-resolution programme implementation.

A SYSTEMATIC REVIEW AND META-ANALYSIS ON THE GLOBAL PREVALENCE OF *PLASMODIUM KNOWLESI*, *P. MALARIAE*, AND *P. OVALE*

Seda Yerlikaya, Ewurama Owusu, Xavier Ding

FIND, Geneva, Switzerland

The World Health Organization (WHO) recommends the parasitological confirmation of all suspected malaria cases using microscopy or quality-assured rapid diagnostic tests (RDTs) before administering antimalarial treatments. However, misclassification of rare *Plasmodium* species such as *Plasmodium knowlesi (Pk*), *Plasmodium malariae (Pm)*, and *Plasmodium ovale* (*Po*) is common by conventional microscopic examination. Moreover, in a recently published systematic review, we showed that malaria RDTs show suboptimal performance for detecting *Pk*, *Pm*, and *Po* mono-infections in human blood. Therefore, national surveillance systems which rely on identification of *Plasmodium*-positive cases by microscopy or RDTs do not provide reliable data on the contribution of these rare species to the global burden of malaria. Therefore, we are currently performing a systematic review and meta-analysis to estimate the global prevalence of human malaria infections caused by *Pk*, *Pm*, and *Po* as identified using molecular diagnostic methods. A systematic search of MEDLINE, EMBASE, Web of Science and CENTRAL databases was performed to identify published studies dating from 1990 which reported data from community surveys of the prevalence of *Pk*, *Pm*, and *Po* species. A total of 6,227 titles were identified to be screened. At the end of the screening process, data from publications eligible for the inclusion in the review will be extracted and sorted by pre-defined variables by two independent investigators. Prevalence data for each *Plasmodium* species will be pooled for each country, and a random effects model will be used to calculate pooled prevalence estimates. Cochrane's Q test and Higgins' I^2 statistics will be used for the assessment of heterogeneity. Sub-group analysis based on the geographic regions, study time periods, and age groups will be conducted to address sources of heterogeneity. This will be the first study to report on the global prevalence of these rare *Plasmodium* species. The data compiled in this review will enable a better understanding of the global malaria burden imposed by *Pk*, *Pm*, and *Po* and galvanize interest further data collection.

SPATIAL EPIDEMIOLOGY OF *PLASMODIUM FALCIPARUM* DRUG RESISTANCE IN THE DEMOCRATIC REPUBLIC OF CONGO

Molly Deutsch-Feldman[1], Ozkan Aydemir[2], Margaret Carrel[3], Nicholas F. Brazeau[1], Samir Bhatt[4], Jeffrey Bailey[2], Melchior Kashamuka[5], Antoinette K. Tshefu[1], Steve M. Taylor[6], Jonathan J. Juliano[1], Steven Meshnick[1], Robert Verity[4]

[1]University of North Carolina - Chapel Hill, Chapel Hill, NC, United States, [2]University of Massachusetts School of Medicine, Worchester, MA, United States, [3]University of Iowa, Iowa City, IA, United States, [4]Imperial College, London, United Kingdom, [5]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, [6]Duke University School of Medicine, Durham, NC, United States

Drug resistant malaria is a growing concern, particularly in the Democratic Republic of the Congo (DRC) where malaria prevalence is 30%. Molecular markers for resistance allow us to monitor the spread of resistant alleles over space and time, and are a critical tool in halting transmission. Previous studies have indicated that sulfadoxine/pyrimethamine (SP) and chloroquine resistant parasites are spatially clustered in the DRC. This study explores how these spatial patterns have changed over time in order to understand how drug resistant malaria may be spreading within the DRC. We selected 540 children with PCR-detectable *Plasmodium falciparum* infection from the 2013 DRC Demographic and Health Survey (DHS). Using molecular inversion probes, we identified known variants in the *pfdhps* and *pfcrt* genes that are associated with SP and chloroquine resistance, respectively. We compared the proportion of single and multiple mutant parasites to those previously reported from 230 adults selected from the 2007 DHS. We used multi-level logisitic models to determine the association between individual and community level factors and the odds of carrying a resistant allele. Finally, we used Markov chain Monte Carlo to fit a spatio-temporal model to the observed data, providing smooth allele frequency estimates over space and time while taking covariates into account. The prevalence of both *pfdhps* and *pfcrt* resistance mutations increased slightly between 2007 and 2013. Additionally, the proportion of double and triple *dhps* mutants increased significantly (p=0.02). The spatial distribution of these mutations highlights hotspots of resistance, with *pfdhps* concentrated in the northeast and *pfcrt* spread across the middle of the country. The spatio-temporal model suggests that the ranges of these hotspots shifted between 2007 and 2013. This study reveals the changing prevalence and geographic distribution of SP and chloroquine resistant *P. falciparum* within the DRC. Close monitoring of resistance with molecular techniques will be a vital part of designing effective intervention strategies to control the spread of drug resistance.

1024

VALIDATING NOVEL SEROLOGICAL MARKERS OF MALARIA EXPOSURE: EVALUATING THE EFFECT OF MASS DRUG ADMINISTRATION (MDA) AND SEASONAL MALARIA CHEMOPREVENTION (SMC) ON TRANSMISSION IN RURAL GAMBIA BASED ON POPULATION-LEVEL ANTIBODY RESPONSES

Lindsey Wu, Muna Affara, Julia Mwesigwa, Simon Correa, Mamadou Bah, Tom Hall, Kevin Tetteh, Jane Achan, Davis Nwakanma, Umberto D'Alessandro, Chris Drakeley

London School of Hygiene & Tropical Medicine, London, United Kingdom

Recent studies have identified a number of novel serological markers highly correlated with recent malaria infection. However, limited studies have assessed their potential use in surveillance or cluster trial evaluation. Using a multiplex immunoassay (MAGPIX) with a panel of 25 *Plasmodium falciparum* antigens, we quantified IgG antibody responses in an all-age longitudinal cohort of 2,688 individuals in rural Gambia as part of a countrywide mass drug administration (MDA) from 2013-2015. We

estimated antibody decay rates following infection and the association between antibody intensity and time since last infection. Combined antibody responses to several antigens (Etramp5.Ag1, HSP40, GexP18, Rh2.2030 and EBA175) showed strong sensitivity and specificity as markers of patent and sub-patent malaria infection in the last 30-150 days. Receiver Operating Characteristic (ROC) analysis showed that Area Under the Curve (AUC) values for ages 1-5 years and 6-15 years were 0.85 (95%CI 0.72-0.91) and 0.85 (0.77-0.92), respectively, but slightly lower for individuals aged greater than 15 years (AUC 0.72 [0.62-0.82]). Antibody responses in the Upper River Region of Gambia following the 2014 transmission season were lower in villages receiving all-age MDA (*N*=823) compared to villages receiving seasonal malaria chemoprevention (SMC) in children under five (*N*=1,155). Seroprevalence to Etramp5.Ag1 was 4.0% (95%CI 3.6-4.5) in MDA villages compared to 8.8% (8.1-9.5) in SMC villages. Similarly, seroprevalence to EBA175 was 4.1% (3.5-4.5) and 8.3% (7.6-9.0) in MDA and SMC villages respectively, and 4.4% (3.8-4.9) and 7.2% (6.6-7.9) to Rh2.2030. Age-adjusted cumulative antibody intensities to several antigens (Etramp5.Ag1, Rh2.2030, EBA175, MSP1.19 and GLURP) were also lower in MDA villages. Findings suggest these biomarkers could have application in routine surveillance or clinical trials to measure short-term changes in malaria transmission. Future research will need to investigate geographical variation in antibody response, determine optimal seropositivity thresholds by antigen and age, and validate their use in cluster-randomised trials.

EFFECT OF REPEATED BED-NET DISTRIBUTIONS AND IMPROVED TREATMENT ON MALARIA INCIDENCE IN SEVEN SENTINEL SURVEILLANCE SITES IN PAPUA NEW GUINEA

Daniela Rodriguez Rodriguez[1], Yangta Ura[2], Anthony Tandarapah[2], Sharon Jamea-Maiasa[2], Peter Siba[2], Ivo Mueller[3], Justin Pulford[4], Manuel W. Hetzel[1]

[1]Swiss Tropical and Public Health Institute, Basel, Switzerland, [2]Papua New Guinea Institute of Medical Research, Goroka, Papua New Guinea, [3]Institut Pasteur, Paris, France, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

The diverse social and ecological environments in Papua New Guinea (PNG) are echoed in intricate human host-parasite-vector interactions, resulting in a complex malaria epidemiology. Increased coverage with long-lasting insecticidal nets (LLIN) and improved diagnosis and treatment (artemisinin-based combination therapy or ACT) have reduced malaria prevalence in PNG since 2008. Yet, national trends in malaria incidence are inconclusive and difficult to interpret due to confounding effects of the scale-up of Rapid Diagnostic Tests (RDT), changes in reporting forms, and inconsistencies in routine reporting. We analyzed malaria incidence trends between 2010 and 2014 in seven sentinel surveillance sites to provide a better understanding of the impact of interventions (LLIN and ACT) in epidemiologically distinct settings across PNG. The analysis included over 34,000 fever cases diagnosed by RDT and light microscopy. Intervention effects on malaria incidence were quantified using multivariate regression models. We found that each site showed a distinct incidence pattern over time. Age distribution of positive cases significantly varied between sites and after each LLIN distribution. Repeated LLIN distributions showed cumulative effects further reducing the number of malaria cases with each round in all sites but one. In comparison ACT introduction only explained a small fraction of the observed reduction of malaria cases. *P. falciparum* remained the dominant source of clinical malaria in all sites. In general terms, our findings confirm the impact of LLIN on malaria incidence in PNG. However we also found significant heterogeneity between sites including an apparent reduction of the effect of interventions in a site in which early and outdoor biting of *Anopheles* mosquitoes has been identified as a threat to the effectiveness of LLINs. Additional targeted interventions seem essential for more effective control and acceleration towards malaria elimination in PNG.

HOST AND PARASITE FACTORS ASSOCIATED WITH *PLASMODIUM FALCIPARUM* INFECTION PERSISTENCE AND GAMETOCYTE PRODUCTION DURING THE DRY SEASON IN THE GAMBIA

Katharine Collins[1], Sukai Ceesay[2], Kjerstin Lanke[1], Muna Affara[2], Chris Drakeley[3], Umberto D'Alessandro[2], **Teun Bousema**[1], Antoine Claessens[3]

[1]Radboudumc, Nijmegen, Netherlands, [2]Medical Research Council The Gambia, Fajara, Gambia, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom

Malaria in The Gambia is seasonal, with virtually all clinical cases occurring during the four month wet season. Some *Plasmodium falciparum* infections may persist the subsequent dry season and constitute the human infectious reservoir at the moment the transmission season starts. It is currently unknown what human and parasite factors are associated with infection persistence and gametocyte production. We established a cohort with 60 *P. falciparum*-positive Gambian participants at the start of the dry season who were bled monthly for 6 months. In collaboration with MalariaGEN, parasite genomes were sequenced to investigate genetic diversity. Gametocyte production and sex ratio was assessed by qRT-PCR targeting male (PfMGET) and female (Pfs25) transcripts and related to total parasite density assessed by varATS and SBP1 qPCR. Naturally

acquired antibody responses to a panel of pre-erythrocyte, blood stage and sexual stage antigens is currently being assessed by luminex and protein microarray. We observed a striking dichotomy in parasite carriage times with 42.5% (17/40) of subjects carrying parasites until the end of dry season (6 months) whilst other subjects typically carried parasites for <2 months. Infections were almost exclusively single clone infections and all infections had detectable gametocytes at one or more occasions. The mean male:female sex ratio was 0.23 (95% confidence interval: 0.17-0.29) and this ratio remained stable during the season and was not associated with gametocyte density. Plasma samples, taken repeatedly, are currently analysed and related to duration of infection. Whilst some infections are cleared rapidly after the transmission season ends, others persist throughout the dry season and continue to produce gametocytes at a sex ratio that is considered suitable for onward transmission. Parasite complexity of infection and host age were not obvious determinants of infection duration; the human antibody profile is current being compared between individuals who rapidly cleared infections and those who retained their infections throughout the dry season.

1027

THE FORMULA "AVERAGE + 2 X STANDARD DEVIATION" APPLIED TO THE FOLLOW-UP OF MALARIA EPIDEMIC WARNING LEVEL AND COMPARISON WITH THE FORMULA OF THE "SIMPLE AVERAGE" THROUGH 18 SITES SENTINELS OF SURVEILLANCE IN SENEGAL FROM 2016 AND 2017

Medoune Ndiop, Moustapha Cisse, Alioune Badara Gueye, Ibrahima Diallo, Seynabou Gaye, Doudou Sene

National Malaria Control Programm, Dakar, Senegal

To predict and control malaria epidemics, the Senegal National Malaria Control Program (NMCP) developed an epidemiological surveillance system of rapid detection. This malaria sentinel system, set up in 2008, includes 24 sites, 18 of which are distributed in low to moderate transmission zones at risk for epidemics. Weekly, the selected health facilities (sites) report the total patients consulted; suspected malaria cases, patients tested by rapid diagnostic tests (RDT), and confirmed malaria cases. Since 2009, 100% of suspected malaria cases have been tested by RDT, and 100 % of positive cases received artemisinin-based combination therapy. In 2016, the NMCP introduced a method of calculating epidemic threshold using historical data for each site dating back five years. For every site, a curve of the epidemic threshold curve is drawn, using the following formula: weekly average of the confirmed cases for a given epidemiologic week over the previous five years plus two standard deviations. In any site, if the threshold is met or exceeded, a systematic documentation of the reported cases is made and an investigation of cases is triggered. During 2016 and 2017, the reported cases were systematically compared weekly with the epidemic threshold curve and the same epidemiological week from the previous year. This formula proved to be very sensitive, with detection of 99% of potential epidemic situations, in contrast with the direct comparison with the previous year's epidemiological week or even compared to using a threshold based on a formula of simple averages. In zones of moderate or high transmission, specific actions are taken based on the results of this documentation. In zones of low transmission, the threshold is one case, and every case is systematically documented and investigated. Since implementation, four sites reached or surpassed the epidemic threshold more than four times. Investigations showed that 80% of cases were imported, and 20% of autochthonous cases did not sleep under insecticide-treated nets.

1028

MONITORING IMPORTED MALARIA CASES IN THE STATE OF RORAIMA, BRAZIL

Jaime Louzada[1], Rispah Abdallah[2], Venkatachalam Udhayakumar[2], Joseli Oliveira-Ferreira[3], Naomi W. Lucchi[2]

[1]Federal University of Roraima, Boa Vista, Brazil, [2]Malaria Branch and Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Institute Oswaldo Cruz, Oswaldo Cruz Foudation -Fiocruz, Rio de Janeiro, Brazil

In Brazil, three states are known to contribute a majority of the malaria infections reported in the country: Amazonas, Para, and Acre. Roraima State is considered low risk for autochthonous *Plasmodium falciparum* transmission with the majority of the infections being *P. vivax*. However, the state has recently seen an increase in the number of reported *P. falciparum* infections believed to be coming from Guyana and Venezuela. The objective of this study was to determine the prevalence of *Plasmodium* species among patients attending health clinics in Boa Vista (state capital), Rorainopolis and Pacaraima (a health post located in the Venezuelan border town) in Roraima State. Information about residence and travel history was collected from all patients. Microscopic diagnosis was made during presentation at the clinic and a blood spot was collected to confirm diagnosis and for species identification using PET-PCR. For PCR, samples were first screened for the presence of *Plasmodium spp; Plasmodium*-positive samples were evaluated for the four human infecting species. A total of 429 patients were enrolled between 2016-2017 in the three sites, Boa Vista (243), Rorainopolis (57), and Pacaraima (129). Twenty six percent reported that they were from Venezuela; 99% of these attended the health post in Pacaraima. Field microscopy identified 161 (38%) *P. vivax* infections, 114 (27%) *P. falciparum* infections and 6 (1%) mixed *P. falciparum* and *P. vivax* infections. Among 286 samples that were *Plasmodium* positive by PCR, 148 (52%) were positive for *P. vivax,* 117 (41%) were positive for *P. falciparum*, and 14 (5%) had mixed infections (*P. falciparum* and *P. vivax*); species could not be identified for 7 samples (2%). Based on residence/travel history, 234 of the 286 (82%) PCR positive patients were thought to have acquired infection in Venezuela or Guyana, including 111 (95%) of the 117 with *P. falciparum* infections. This finding needs to be considered when developing control interventions.

1029

INCREASING PREVALENCE OF *PLASMODIUM OVALE* INFECTIONS IN THE DEMOCRATIC REPUBLIC OF THE CONGO: INSIGHT INTO A NEGLECTED MALARIA SPECIES

Cedar Mitchell[1], Nicholas Brazeau[1], Corinna Keeler[1], Kashamuka Mwandagalirwa[1], Antoinette Tshefu[2], Madeline Denton[1], Kyaw Thwai[1], Jonathan B. Parr[1], Steven R. Meshnick[1], Jonathan J. Juliano[1]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [2]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo

Of the five species of malaria capable of infecting humans, *Plasmodium ovale* has largely evaded the attention of the malaria research community. Consequently, little is known about the distribution and occurrence of ovale malaria in the high endemicity regions of sub-Saharan Africa. As falciparum malaria continues to decline in these regions, non-falciparum parasites, such as *P. ovale*, may become more important sources of malaria infections. We are using real-time PCR on 25,945 dried blood spots from the 2013-14 Demographic Health Survey (DHS) in the Democratic Republic of the Congo (DRC) to investigate the prevalence of *P. ovale* infections, its distribution, and risk factors for infection. Preliminary screening of 7,607 adult samples identified 213 positives, consistent with a prevalence estimate around 3%. This is considerably higher than our prior 0.4% prevalence estimate from the 2007 DHS. After completing the screening of all samples, the prevalence of infection by *P. ovale* and its subspecies, *P. ovale curtisi* and *P. ovale wallikeri,* will be mapped to examine the spatial

distribution of infections. Additional epidemiological analyses to evaluate risk factors for infection, including bed net use and co-infections with *Plasmodium falciparum* and *Plasmodium vivax,* will be performed. Insight into the epidemiology of *P. ovale* in the DRC is an important starting point for improving our understanding of the burden of non-*falciparum* malaria in one of the most malarious regions of the world.

1030

OPTIMIZATION OF THE ARTEMISININ RESISTANCE MAPS FOR COMMUNICATION TO THE POLICY MAKERS IN SOUTHEAST ASIA (UTILIZATION OF END-USER USABILITY ASSESSMENT AS PART OF HUMAN-CENTERED DESIGN)

Frank M. Kagoro[1], Richard Maude[1], Kevin Marsh[2], Mehul Dhorda[1], Nattwut Ekapirat[1], Chris Mercado[1]

[1]Mahidol Oxford Tropical Medicine Research Unit (MORU), Bangkok, Thailand, [2]Center for Tropical Medicine and Global Health, University of Oxford, Oxford, United Kingdom

Despite maps having been used for centuries as visual tools for communication, analysis and planning, there are no studies that have shown how to produce efficient audience specific maps. In the current efforts to eliminate malaria in South-East Asia, there has been a significant effort of mapping the burden of artemisinin resistance, none of these maps however have been evaluated to see how they perform as intended. Since various maps are produced from different cartographic techniques, there is a threat of such maps leading to poor planning and hence jeopardise elimination efforts.This study aimed at introducing a technique of how to develop a cartographic framework for guiding such work by integrating the cartographic skills from published information, expert opinion and user characteristics to develop relevant maps to aid malaria elimination plan.As first part of the work, cartographic techniques from relevant articles were summarised and used to develop various maps using the malaria genetic markers data summarised by WorldWide Antimalarial Resistance Network (WWARN). In order to communicate the correct scientific information, expert opinion was sought to review the drafted maps and maps revision was done according to the feedback. Lastly, to incorporate the 'National Malaria Control Programme (NMCPs) personnel's specific features' and evaluate their understanding of the maps, a user-centred qualitative assessment was done to obtain a structured feedback. Despite few respondents were obtained, the analysed feedback was used to optimise maps to produce the final genetic artemisinin resistance maps for communication to the policy makers. This presentation aims at explaining this process, and how the obtained feedback was used to optimise the drafted maps to produce the final maps for the NMCP personnel in South-East Asia.

1031

NET INTEGRITY DOES NOT PREDICT *PLASMODIUM FALCIPARUM* INFECTION AMONG ITN USERS IN SOUTHERN MALAWI, 2012-2014

Liana R. Andronescu[1], Andrea G. Buchwald[1], Jenna E. Coalson[2], Lauren M. Cohee[1], Andy Bauleni[3], Kondwani Nkanaunena[3], Andrew Ngwira[3], Andrew Mzomera[3], Don P. Mathanga[3], Miriam K. Laufer[1]

[1]University of Maryland School of Medicine, Baltimore, MD, United States, [2]University of Arizona, Tucson, AZ, United States, [3]University of Malawi College of Medicine, Blantyre, Malawi

Mass distribution campaigns have increased the use of insecticide treated nets (ITNs) in Malawi, but *Plasmodium falciparum* infection prevalence remains high even among those using ITNs. Previous studies have addressed barriers to ITN use but there is limited information explaining the high prevalence of infection among ITN users. We assessed the impact of ITN integrity on protective efficacy among self-identified ITN users who reported sleeping under a net the night before the interview. From 2012 to 2014, six cross-sectional surveys were conducted in the rainy and dry seasons in southern Malawi. Data were collected on ITN use, number of people sharing each ITN, ITN age, and ITN integrity. ITN integrity was measured based on the number of holes the size of a torch battery in each ITN. Blood samples were obtained from all subjects over 6 months of age, and microscopy and qPCR were used to detect *P. falciparum* infection. Mixed effect logistic regression was used to calculate odds ratios for infection and account for clustering at the household and community level. Overall, there were 9,646 ITN users, of whom 15% tested positive for *P. falciparum* infection. Among net users, 22% were children under 5 years, 29% were children 5 - 15 years, and 49% were 15 years or older. Over half of participants (55%) reported sleeping more than two household members under an ITN, of whom 1,565 (16%) reported sleeping 4 or more people under an ITN. Among net users, preliminary results indicate that after adjusting for sex, age, number of persons sharing a net, survey number, and open eaves, better ITN integrity was not significantly associated with a decreased risk of infection (OR: 1.09, 95% CI: 0.91, 1.31), suggesting that ITN integrity is not a strong predictor of ITN protective efficacy.

1032

ASYMPTOMATIC CARRIAGE OF *PLASMODIUM FALCIPARUM* AND NON-*P. FALCIPARUM* INFECTIONS IN INDIVIDUALS WITH AND WITHOUT HIV

Individuals co-infected with HIV and malaria coinfection have have more episodes of clinical malaria and therefore more likely to have higher asymptomatic malaria carriage than non HIV infected individuals. However, while asymptomatic malaria represents the largest reservoir of malaria transmission, many of the of HIV malaria co-infections studies in sub Saharan Africa focus on *Plasmodium falciparum* infections, with little attention being paid to non-falciparum infections. Additionally, diagnosis of the different malaria species has been made difficult by mixed infections with other Plasmodium species and low parasitemia levels. We therefore sought to use sensitive molecular techniques to determine the point prevalence *P. falciparum, P. ovale* and *P. malariae* infections in HIV-infected and HIV-uninfected participants, as well as the overall study population. Using 1100 samples collected in a HIV/malaria co-infection study in a malaria endemic region in western Kenya, the presence of any species of malaria was first determined using an improved assay based on genus-conserved sequences of the Plasmodium 18S ribosomal gene. All infections with ≥1 parasite per 50ul sample were detectable by our assay. Second, if positive for malaria, panels of highly species-specific qPCR assays were developed to determine the presence and quantity of *P .falciparum, P. ovale* and *P. malariae* as single or mixed infections;We will report the point prevalence and magnitude of infection with single and/or multiple species in both HIV-infected and non-HIV-uninfected persons. So far, preliminary results show that our quantitative PCR assays are sensitive and can be used on samples from malaria endemic areas where high prevalence of sub-microscopic parasitaemia have been reported. The relevance of this study is that HIV-malaria co-infected individuals may be more efficient reservoirs of malaria and therefore there is need for higher public health priority of persons at risk for both diseases.

MALARIA IN PREGNANCY: FROM PRE-CONCEPTION TO EARLY PREGNANCY, A GENOTYPING ANALYSIS

Sayeh Jafari-Guemouri[1], Manfred Accrombessi[2], Emmanuel Yovo[2], Achille Massougbodji[2], Nicaise NDam[1], Xavier Ding[3], Michel Cot[1], Nadine Fievet[1], **Valerie Briand**[1]

[1]UMR216, French National Research Institute for Sustainable Development (IRD)-Université Paris Descartes, Sorbonne Paris Cité, Paris, France, [2]Centre d'Etude et de Recherche sur le Paludisme Associé à la Grossesse et à l'Enfance (CERPAGE), Faculté des Sciences de la Santé, Université d'Abomey-Calavi, Cotonou, Benin, [3]FIND, Geneva, Switzerland

In Sub-Saharan Africa, preventive strategies against malaria in pregnancy are based on long-lasting insecticide treated bed nets and intermittent preventive treatment in pregnancy (IPTp) with sulfadoxine-pyrimethamine, which are usually not implemented before the 2nd trimester of pregnancy. Therefore, women remain unprotected or insufficiently protected against malaria during the first months of pregnancy, when malaria has been suggested to be particularly deleterious for the fetus. RECIPAL is a recently completed pregnancy cohort with pre-conceptional recruitment in Benin. From 2014 to 2017, 411 pregnant women were followed from the very first weeks of gestation until delivery, with monthly screening for malaria using microscopy and Polymerase Chain Reaction (PCR). We previously demonstrated that women were two times more likely to have microscopic malaria in early pregnancy than before pregnancy, and that these infections occurred as early as 5-6 weeks of gestation. The risk of malaria infection in the first trimester was highly predicted by microscopic infections occurring before conception, suggesting that malarial infections detected in the first trimester were already present before pregnancy. Our hypothesis is that these pre-pregnancy infections are submicroscopic (ie, detected by PCR but not by microscopy) and they become patent (microscopic) because of changes in women's physiology and immunity during early pregnancy. Using a fragment-analysis method, we are investigating if parasites detected before pregnancy and during the first trimester have the same genotypes. Three highly polymorphic markers in *Plasmodium falciparum* (*msp-1*, *msp-2* and *Glurp*) are used to determine all the genotypes present in each isolate. If this hypothesis is confirmed, our results may argue in favor of starting preventive strategies against malaria as early as the pre-conceptional period.

HETEROGENEOUS DISTRIBUTION OF *PLASMODIUM VIVAX* AND *FALCIPARUM* CARRIAGE ON THE BORDER AREA BETWEEN BRAZIL AND FRENCH GUIANA

Emilie Mosnier[1], Emmanuel Roux[2], Claire Cropet[3], Yassamine Lazreck[4], Mélanie Gaillet[1], Luana Mathieu[4], Mathieu Nacher[3], Franck De Laval[5], Stephane Pelleau[4], Maylis Douine[3], Philippe Abboud[6], Bastien Bidaud[1], Félix Djossou[6], Lise Musset[4]

[1]Pôle des Centres Délocalisés de Prévention et de Soins, Centre hospitalier Andrée Rosemon, Cayenne, French Guiana, [2]UMR 228 Espace-Dev, Espace pour le développement, Montpellier, France, [3]Centre d'Investigation Clinique Epidémiologie Clinique Antilles Guyane, Centre hospitalier Andrée Rosemon, Cayenne, French Guiana, [4]Laboratoire de parasitologie, WHO CC for surveillance of antimalarial drug resistance, CNR Paludisme Pôle Zones endémiques, Institut Pasteur de la Guyane, Cayenne, French Guiana, [5]French Armed Forces Health Service, Cayenne, French Guiana, [6]Unité de Maladies Infectieuses et Tropicales, Centre Hospitalier Andrée Rosemon, Cayenne, French Guiana

French Guiana and its Eastern border with Brazil was considered as a low to moderate malaria transmission area. Recent population surveys with PCR analyses in low endemic settings area reported a majority of asymptomatic carriage. In the perspective of malaria elimination, characterization of the infectious reservoir is recommended. A cross-sectional survey was conducted between October and December 2017, enrolling inhabitants from a village bordering Brazil. The prevalence of *Plasmodium* spp. carriage was measured with Rapid Diagnostic Tests (RDT) and real-time polymerase chain reaction (PCR). Houses were georeferenced. Demographics, medical history, clinical and findings were reported and analyzed according to Plasmodium spp. carriage. Geographical clustering analysis (SaTScan) as well as multivariate risk factor analysis were also performed. PCR showed that 100 of 1,501 participants carried *Plasmodium* spp. , 90% *P. vivax* (Pv) and 10% *P. falciparum* (Pf). Only 13/1,549 people tested by RDT were positive. The final PCR positivity rate was 6.66% with a large variation between neighborhood from 0 to 29,5%. Seventy four percent of infections were asymptomatic. The risk of malaria carriage was significantly high in three neighborhoods (Trois Palétuviers: RR=7.16, p<0.01, Adimo: RR=12.43, p=0.046 and Blondin2: RR=5.15, p=0.002). In the multivariate analysis, an age over 15 years old, living in remote neighborhoods, a previous history of malaria, anemia and low platelets were independently associated with an increased odds of *Plasmodium spp*. Carriage. Bed net use was not associated with a reduced odds of carriage. Malaria carriers often lived in remote areas, close to the forest. The current study adds to available evidence on the wide-scale but heterogeneous spatial distribution of asymptomatic parasitemia in this area. Asymptomatic malaria is associated with anemia and low platelets and could have an impact on health. Further unravelling the epidemiology of malaria with early identification of symptomatic and asymptomatic infection can enable public policy to define interventions likely to accelerate elimination efforts.

1035

EFFECT OF CONTROL INTERVENTIONS ON THE MALARIA RISK PROFILE IN UGANDA

Simon P. Kigozi[1], Ruth N. Kigozi[2], Arthur Mpimbaza[3], Asadu Sserwanga[4], Sarah G. Staedke[5], Adoke Yeka[6], Moses R. Kamya[7], Grant Dorsey[8], Rachel L. Pullan[1]

[1]Department of Disease Control, London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]U.S. Agency for International Development's Malaria Action Program for Districts, Kampala, Uganda, [3]Child health and development centre, Makerere University College of Health Sciences, Kampala, Uganda, [4]Infectious Disease Research Collaboration, Kampala, Uganda, [5]Department of Clinical Research, London School of Hygiene & Tropical Medicine, London, United Kingdom, [6]School of Public Health, Makerere University College of Health Sciences, Kampala, Uganda, [7]School of Medicine, Makerere University College of Health Sciences, Kampala, Uganda, [8]Department of Medicine, University of California San Francisco, San Francisco, CA, United States

Improved malaria control, predominantly including long lasting insecticidal nets (LLIN) and indoor residual spraying, has been associated with reduced malaria burden throughout Africa. However, less is known about how control efforts may modify associations between age and malaria risk. We investigated the possible impact of control efforts on these associations using routine malaria surveillance data in Uganda. We used 10 years of data from five government-run level IV health facilities in five areas with varied transmission intensity. Data included children 11 years or younger, who presented to outpatient departments with suspected malaria, and underwent laboratory testing using microscopy or rapid diagnostic tests. We divided data into three intervention-periods: 'limited intervention', 2007 - 2009; 'pre- 1st mass LLIN distribution', 2010 - 2013/2014; and, 'post- 1st mass LLIN distribution', 2013/2014 - 2017. Logistic regression was used to estimate associations between age and diagnostically confirmed clinical malaria, controlling for site, month, and diagnostic test used, after stratifying by intervention-period. A total of 338,590 children were seen during the study period: 88,362, 138,186 and, 103,829 during the limited intervention, pre- 1st mass LLIN distribution, and post- 1st mass LLIN distribution periods, respectively. Relative to the 0 - 1 year age group, the odds of having clinical malaria were highest among the 2 - 3 year age group (OR= 1.59 95% CI 1.51-1.68, p<0.001) during the limited intervention period, then among the 5 - 6 year age group (OR= 1.89 95% CI 1.80-1.99, p<0.001) during the pre-1st mass LLIN distribution period, and among the 6 - 7 year age group (OR= 2.48 95% CI 2.33-2.64,

p<0.001) during the post- 1st mass LLIN distribution period. These results show that as malaria control activities were scaled up, the age group with the highest risk of clinical malaria increased. Thus, policies and surveillance programs that have historically targeted children under the age of 5 years should consider broadening their scope to older age groups, such as school-age children, following expansion of control interventions.

Genetically distinct pathogen populations can occupy geographically distinct niches and may exhibit differing transmission dynamics. *Plasmodium falciparum* genetic diversity is indicative of endemicity, with high genetic diversity and limited population structure indicating extensive gene flow and mixing of parasite populations. As transmission decreases, parasite populations exhibit lower diversity due to increased inbreeding. Reduced gene flow results in population structure and emergence of distinct genetic clusters or 'demes'. *P. falciparum* genotype data, however, has not previously been used for spatial prediction of genotype clusters. This study uses a Dirichlet regression model to examine associations of *P. falciparum* genotype clusters from 27 survey locations across Papua New Guinea with latitude and longitude, elevation, population density and Euclidean distance to the coastline. Genotype clusters were determined based on ancestry co-efficients derived from Bayesian cluster analysis of 708 *P. falciparum* isolates genotyped with 154 single nucleotide polymorphisms (SNPs). The regression model was used to predict the spatial distribution of eight distinct genotype clusters of *P. falciparum* across PNG. Statistically significant associations were found between latitude and longitude and six genetic clusters. Four clusters were associated with distance to the coastline and population density, and two clusters associated with elevation. Genotype clusters were found to occupy distinct geographic niches in PNG including at least two populations on the mainland that are distinct from those of outlying islands. The results identify potential gene flow between neighbouring areas of high transmission connected by population movement. The definition of distinct demes divides the PNG parasite population into regional blocks that could be independently targeted for control and elimination. Defining the spatial distribution of parasite populations is essential for evaluating the efficacy of malaria control programmes and provides essential tools for planning targeted control efforts for malaria elimination.

PREVALENCE OF PLACENTAL MALARIA AMONG PREGNANT WOMEN IN THE MIDDLE BELT OF GHANA

Jones Opoku-Mensah, Kenneth Asayah, Kwaku Poku Asante

Kintampo Health Research Centre, Kintampo, Ghana

Malaria in pregnancy is a major public health concern, causing maternal, foetal and infant morbidity and mortality. Placenta malaria (PM) is a complication of malaria in pregnancy which leads to adverse outcome in pregnancy such as stillbirth, low birth weight, preterm delivery, abortion and maternal anaemia. The study investigated the prevalence of PM among a cohort of pregnant women in the meddle belt of Ghana. Maternal peripheral blood, cord blood and placenta tissue samples were obtained from 1148 women for histopathological examination to ascertain the presence of malaria parasitization. This was one of the study procedures for the Ghana Randomised Air Pollution and Health Study (GRAPHS) which sought to examine the impact of cleaner cookstoves on child health. Each sample was categorized by a histopathologist as showing no infection, acute infection, chronic infection, or past infection based on a standard classification. The study was conducted in the Kintampo North Municipality and Kintampo South District located in the middle belt of Ghana from September 2013-March 2016. Among the 1,148 placenta tissues collected and analysed using placental histology, 24.3% (279/1148) showed histological evidence of malaria parasitization. Of the 279 PM cases, 21.9% (61/279) showed acute infection, 20.4% (57/279) showed chronic infection, while 63.8% (178/279) showed past infection. There is the need for the Ministry of Health and the Ghana Health Service to institute policies that improve the uptake of sulfadoxine-pyrimethamine during pregnancy to prevent PM. In conclusion, this study showed that the prevalence of PM in the middle belt of Ghana is still high especially for women with past PM infection.

DEVELOPMENT OF SEROLOGICAL MARKERS FOR DETECTING RECENT EXPOSURE TO *PLASMODIUM VIVAX* MALARIA

Michael White[1], Rhea J. Longley[2], Eizo Takashima[3], Jessica Brewster[2], Masayuki Morita[4], Matthias Harbers[5], Leanne Robinson[2], Shih-Jung (Zoe) Liu[2], Connie Li Wai Suen[2], Wai-Hong Tham[2], Julie Healer[2], Xavier C. Ding[6], Iveth J. Gonzalez[6], James Kazura[7], Marcus Lacerda[8], Jetsumon Sattabongkot[9], Takafumi Tsuboi[3], Ivo Mueller[2]

[1]Institut Pasteur, Paris, France, [2]Walter and Eliza Hall Institute, Melbourne, Australia, [3]Ehime University, Matsuyama, Japan, [4]Ehime University, Melbourne, Japan, [5]CellFree Sciences and RIKEN Center for Integrative Medical Sciences, Tokyo, Japan, [6]Foundation for Innovative New Diagnostics, Geneva, Switzerland, [7]Case Western Reserve University, Cleveland, OH, United States, [8]Fundacão de Medicina Tropical Dr. Heitor Vieira Dourado, Manaus, Brazil, [9]Mahidol University, Bangkok, Thailand

The future transition from malaria control to elimination will bring a number of challenges, one being the dominance of *Plasmodium vivax* in many regions with decreasing transmission. *P. vivax* cases are often asymptomatic with low-density infections, so escape detection via traditional surveillance methods. *P. vivax* hypnozoites (arrested liver-stages) cannot be directly detected using even sensitive molecular tools. Instead, it is proposed that hypnozoite carriers may be indirectly identified by measuring antibody responses to past blood-stage infections. A panel of over 300 serological markers was screened for ability to induce IgG responses in individuals exposed to *P. vivax* in Thailand and Brazil. The kinetic profile of these antibody responses over 9 months in the absence of recurrent infections was characterised. Candidate serological markers were down-selected to a panel of 60 based on high immunogenicity at the time of infection, and similar estimated antibody longevity between the two geographic sites. The down-selected panel of 60 proteins was further validated in three independent observational cohorts conducted in Thailand, Brazil and the Solomon Islands plus three panels of negative controls, constituting observations from more than 3,000 individuals. By measuring antibody responses at the last visit of these cohorts, and relating them to the time since last confirmed *P. vivax* infection, a strong association between antibody titer and time since exposure was confirmed. Classification algorithms were used for a final down-selection to a panel of 8 *P. vivax* proteins that can accurately classify whether an individual has had a *P. vivax* infection within the last 9 months or not. Cross-validated classification algorithms were developed that can identify individuals infected within the last 9 months with greater than 80% sensitivity and specificity. This technology can be used as the basis of a serological screening and treatment strategy allowing primaquine treatment for elimination of hypnozoites to be optimally targeted at only those individuals who need it.

1039

SUBMICROSCOPIC MALARIA INFECTIONS IN ASYMPTOMATIC INDIVIDUALS AT MILITARY HEALTH FACILITIES IN CENTRAL VIETNAM

Nguyen N. San[1], Marina Chavchich[2], Michael D. Edstein[2], Nicholas J. Martin[3], Nguyen D. Manh[1]

[1]Vietnam People's Army Military Institute of Preventive Medicine (MIPM), Hanoi, Vietnam, [2]Australian Army Malaria Institute (AAMI), Brisbane, Australia, [3]US Naval Medical Research Center-Asia (NMRC-A), Singapore, Singapore

In Vietnam, malaria cases markedly decreased between 2000 and 2015 from about 210,000 to 13,000 cases (i.e., 94% reduction). The Vietnamese Ministry of Health has set a goal for the country to be free from malaria by 2030. To understand true infection rates, the prevalence of submicroscopic infections in asymptomatic individuals should be considered, so that malaria interventions programs such as mass drug administration can be evaluated. In assisting this process MIPM in collaboration with AAMI and NMRC-A conducted a cross-sectional malaria survey in people living in Gia Lai Province between December 2016 and January 2017. Training of MIPM personnel in molecular methods was conducted at AAMI to detect submicroscopic parasitemia. Asymptomatic individuals presenting at 20 military health facilities in malaria endemic areas near the border of Vietnam and Cambodia were invited to participate in the study and those who gave consent were given a questionnaire to obtain demographics data and information on the use of malaria prevention methods. Finger prick blood samples were collected on filter paper to determine the incidence of submicroscopic parasitemia for the five human *Plasmodium* species by PCR. The DNA extraction and multiplex PCR methods were optimized and the criterion for acceptance of the PCR results was a detection threshold of at least 2.5 parasites/μL of blood. PCR screening of blood spots from 3,298 asymptomatic participants by MIPM revealed 7.7% positive samples with 3.9%, 2.1% and 1.0% for *P. falciparum, P. vivax and P. malariae,* respectively, with the remaining 0.7% as mixed infections. This incidence is likely to be an overestimation and the results will be confirmed if at least 2 out 3 positive PCRs are achieved. The molecular markers of drug resistance in *P. falciparum* samples will be characterized and the final results on submicroscopic malaria prevalence and malaria exposure will be presented. Sub-clinical malaria represents a disease reservoir that should be considered when determining the malaria risk for naïve personnel, such as deploying military working in areas with low clinical, but higher sub-clinical malaria rates.

1040

PREVALENCE AND RISK FACTORS ASSOCIATED WITH MALARIA INFECTIONS IN AREAS WITH PERSISTENT TRANSMISSION FROM NORTHWESTERN AND SOUTHERN REGIONS OF TANZANIA

Mercy G. Chiduo[1], Fibert Francis[1], Celine Mandara[1], Susan Rumisha[2], Misago Seth[1], Williams Makunde[1], Method Segeja[1], Frank Chacky[3], Renatha Mandike[3], Sigsbert Mkude[3], Fabrizio Molteni[3], Bruno Mmbando[1], Ally Mohammed[3], Deusdedith Ishengoma[1]

[1]National Institute for Medical Research, Tanga, United Republic of Tanzania, [2]National Institute for Medical Research, Dar-es-salaam, United Republic of Tanzania, [3]National Malaria Control Programme, Dar-es-salaam, United Republic of Tanzania

Despite a recent decline of malaria in Tanzania, there is still high burden in the southern and nothwestern regions; despite high coverage of long-lasting insecticidal nets (LLINs) (ownership >80 and use >66%). This study asessed the prevalence and risk factors associated with persistence of malaria parasite burden in selected regions of Tanzania. A cross-section study was conducted in 8 districts from 4 regions of Kigoma, Geita, Mtwara and Ruvuma, between September and November 2017. Sixteen villages (2 in each district) were selected based on the burden of malaria reported in health facility records, and 120 households (HHs) were selected in each village for parasitological evaluation. All individuals from these HHs were assessed clinically and finger prick samples were collected for detection of parasites by malaria rapid test (mRDTs). Thin and thick smears were prepared for microscopy and demographic as well as socio-economic status (SES) data were also collected. A total of 7,313 individuals (from 2,527 HHs) with median age of 13.0 years were examined. The positivity rate (PR) by mRDTs was 33.3% (ranged from 21.9 to 41.1%) while the PR was 20.6% microscopy (varied from 27.3% to 8.0%); with the highest PR (by both mRDTs and microscopy) in children aged 5-14years (49.0% and 32.8%, respectively). After adjusting for age, sex, anaemia, family size, bed-net use, district and SES, the risk of carrying malaria parasites was lower in females compared to males (AOR= 0.55, 95% CI:= 0.48 – 0.64, p<0.001) but higher among individuals without bed-nets (AOR = 1.22, 95% CI:=1.09 – 1.38, p=0.001), and children aged 5-14yrs (AOR=2.26, 95% CI:=1.96 – 2.61, p<0.001) compared to 0-4yrs. The risk was lower among individuals from households with middle (AOR=0.89, 95% CI:=0.77 – 1.03,p=0.138) and high SES (AOR=0.81, 95% CI:=0.70–0.931,p=0.005).) Although the study was conducted during the low malaria transmission season, high prevalence was reported indicating that malaria is still a problem in the study areas. Targeted interventions are required in these and other areas with persistently high malaria transmission to reach the pre-elimination targets by 2020.

1041

USING ROUTINE ANTENATAL-CARE BASED RDT TESTING TO MEASURE POPULATION TRANSMISSION: THE KEY ROLE OF PREGNANCY-SPECIFIC PATTERNS OF SUSCEPTIBILITY AND IMMUNITY

Patrick Walker[1], Matt Cairns[2], Julie Gutman[3], Carole Khairallah[4], Aaron Samuels[5], Larry Slutsker[6], Kammerle Schneider[6], Steve Meshnick[7], Linda Kalilani-Phiri[7], Victor Mwapasa[8], Steve Taylor[9], Mwayi Madanitsa[10], Meghna Desai[11], Feiko ter Kuile[4]

Increasingly, malaria endemic countries are routinely testing pregnant women for malaria using Rapid Diagnostic Tests (RDTs) at antenatal care (ANC). These tests are likely to be well distributed over time and space: ANC is available year-long and over 90% of pregnant women in these countries attend ANC. If routine RDT testing at ANC can be used to estimate general population prevalence, they would provide an invaluable resource to measure malaria prevalence at much higher spatio-temporal resolution than population-based surveys and more reliably interpret observed temporal trends within case-reporting systems. However, as with all sentinel surveillance approaches, it is necessary to consider and account for potential biases. We evaluated the key role of pregnancy-specific immunology in determining RDT performance and prevalence within ANC and explored how this relates to transmission and population prevalence by fitting a model of the transmission dynamics of malaria to RDT performance data outside of pregnancy and from trials of Intermittent Screening and Treatment in pregnancy. We estimate that, compared to parasite detection using RDTs in non-pregnant women, the odds of detecting a PCR-positive infection at enrollment in primigravidae using an RDT were 16.6 (14.3-19.2 95% C.I) times higher

but that pregnancy-associated boosting of sensitivity declines rapidly as a function of a woman's exposure to malaria in previous pregnancies, and when women are re-tested later in pregnancy. Through simulation we show that this effect is likely to explain, at least partially, why RDT prevalence in pregnancy matches or exceeds that in children in areas of low transmission but progressively becomes an underestimate in areas of higher transmission. Due to this boosting effect, we anticipate ANC prevalence trends will lag behind changes in transmission to a greater degree than those in the general population, an effect which appears in data comparing continuous surveys in Western Kenya. Future ANC-based surveillance approaches will need to account for these effects in order to provide reliable estimates of population-based transmission trends.

1042

PERSISTENT *PLASMODIUM FALCIPARUM* INFECTION IN NON PREGNANT WOMEN IS A RISK FACTOR FOR PREGNANCY-ASSOCIATED MALARIA

Bernard Tornyigah[1], Akpéyédjé Yannelle Dossou[2], Guillaume Escriou[3], Morten A. Nielsen[4], Ali Salanti[4], Saadou Issifou[2], Achille Massougbodji[2], Jean-Philippe Chippaux[3], Philippe Deloron[3], **Nicaise Tuikue Ndam**[1]

Pregnant women are more susceptible to *Plasmodium falciparum* than before pregnancy, and infection has consequences for both mother and offspring. WHO recommends that pregnant woman in areas of transmission receive intermittent preventive treatment starting in the second trimester. Consequently, women are not protected during the first trimester, although *P. falciparum* infections are both frequent and harmful. A cohort of nulligravidae women was followed during subsequent pregnancy. Malaria was diagnosed by microscopy and PCR. Parasites were genotyped at polymorphic loci. Among 275 nulligravidae enrolled, 68 women became pregnant and were followed during pregnancy. Before pregnancy, *P. falciparum* prevalence rates were 15% by microscopy and 66% by PCR. Microscopic infections increased to 29% until IPT administration and their density has been increased by 20 fold on average. Conversely submicroscopic infections decreased in favor of more microscopic infections. Following IPT administration, all types of infections decreased, but increased again late in pregnancy. The risk of infection during pregnancy was higher in women with a microscopic (OR = 2.2, p = 0.001) or submicroscopic (OR = 1.52, p = 0.0001) infection before pregnancy. Most infections during pregnancy were persistent infections acquired before pregnancy. Using a transcription profiling analysis approach, we are investigating the molecular basis of *in vivo* switching of var genes expression. All of these results will be discussed during the congress with their involvement in the prevention strategies of placental malaria.

1043

RAPID INCREASE AND NORTHWARD SPREAD OF ARTEMISININ RESISTANT *PLASMODIUM FALCIPARUM* IN LAOS

Moritoshi Iwagami[1], Masami Nakatsu[1], Phonepadith Khattignavong[2], Pheovaly Soundala[2], Lavy Lorphachan[2], Sengdeuane Keomalaphet[2], Phonepadith Xangsayalath[3], Emilie Matsumoto-Takahashi[1], Virginie Pommelet[2], Bouasy Hongvanthong[4], Paul T. Brey[2], **Shigeyuki Kano**[1]

[1]National Center for Global Health and Medicine, Tokyo, Japan, [2]Institut Pasteur du Laos, Ministry of Health, Vientiane, Lao People's Democratic Republic, [3]National Institute of Public Health, Ministry of Health, Vientiane, Lao People's Democratic Republic, [4]Center of Malariology, Parasitology and Entomology, Ministry of Health, Vientiane, Lao People's Democratic Republic

The emergence and transnational spread of artemisinin resistance in *Plasmodium falciparum* in the Greater Mekong Subregion (GMS) is a serious threat to malaria elimination in the region and could present a threat to malaria control in Africa. Recently, the Lao government adopted the ambitious goal of malaria elimination by 2030, for which monitoring of artemisinin resistant malaria within the country is indispensable. The objective of present study was to assess the distribution of K13 mutations in Laos, which are associated with artemisinin resistance. We collected 1,151 *P. falciparum* isolates from five southern provinces in Laos from 2015 through 2016, and one isolate from the northern-most province bordering China in 2017. We analyzed polymorphisms of the K13 gene and two flanking regions. Overall, 55.5% possessed non-synonymous K13 mutations (C580Y, P574L, R539T, Y493H). The frequencies of the K13 mutations were heterogeneous in the five southern provinces, but with a clear tendency showing the highest frequency in the south (72.5%) and to a lower degree when moving northward (28.0%). The one isolate from the Lao-Chinese border also possessed the C580Y mutation. Analysis of the flanking loci demonstrated that this isolate from the Lao-Chinese border was genetically very close to the resistant lineage originating from western Cambodia, where the first case of artemisinin resistance was reported. Artemisinin resistance was observed to be rapidly increasing and spreading northwards through Laos and has now reached the Chinese border. The Lao and Chinese governments, as well as the international community, should make dedicated efforts to contain the spread of K13 mutations within Laos and in the GMS to avoid its spreading to Africa.

1044

PRIORITIZING THE SCALE UP OF INTERVENTIONS FOR MALARIA CONTROL AND ELIMINATION

Peter Winskill[1], Patrick Walker[1], Edith Patouillard[2], Richard Cibulskis[2], Azra Ghani[1]

[1]Imperial College London, London, United Kingdom, [2]Global Malaria Programme, World Health Organization, Geneva, Switzerland

The World Health Organization recommends a core set of intervention and treatment options for use against *Plasmodium falciparum* malaria. These consist of treatment, long lasting insecticide treated bed nets, indoor residual spraying and a number of chemoprevention approaches. Given the resource limitations many malaria endemic countries face the introduction and scale-up of intervention and treatment options must be prioritised. We combined estimates of the cost of different interventions with a mathematical model of intervention impact to estimate the most cost-effective prioritisation of interventions in different epidemiological settings. Starting from zero coverage, each intervention was assessed at fixed steps in coverage and the most cost-effective (as determined by the incremental cost effectiveness ratio, ICER) chosen. Across all settings, vector control was selected first as the most cost-effective initial intervention with treatment included once moderate levels of vector control were achieved. Prevention through vector control reduces the incidence of malaria, thereby allowing treatment to be implemented

more cost-effectively as well as reducing the stress on the health system. Chemopreventive measures were selected alongside treatment scale-up. It is vital that investments in the available tools be effectively prioritised to maximise the impact for a given investment. The cornerstones of malaria control: vector control and treatment, remain key to efforts, but questions of when to scale and when to introduce other interventions must be rigorously assessed. Strong surveillance is key to informing such prioritisation.

AGE-RELATED RISK CLINICAL MALARIA OVER TIME IN A HIGHLAND AREA OF KENYA DURING A PERIOD OF DECREASING MALARIA TRANSMISSION FOLLOWED BY AN EPIDEMIC

Lindsey B. Turnbull[1], George Ayodo[2], Eliud Onyango[2], Chandy C. John[1]

[1]Indiana University School of Medicine, Indianapolis, IN, United States, [2]Kenya Medical Research Institute, Kisumu, Kenya

Continued progress towards global elimination of malaria requires additional knowledge into how to achieve zero transmission and maintain malaria-free regions within countries that have ongoing transmission in neighboring areas. We have conducted longitudinal surveillance of clinical and asymptomatic malaria in the Kenyan highland areas of Kipsamoite and Kapsisiywa, areas of of unstable transmission, since 2002. To investigate potential changes in clinical immunity over this time, we assessed age specific incidence of clinical malaria in this community from 2002-2017. Malaria incidence decreased after 2005, and an epidemic occurred in 2017. In 2002-2005, malaria incidence was highest in individuals <15 years old: malaria episodes/1000 person-years (incidence rate ratio [95% confidence interval]) compared to <5 year old group; <5 y, 59.0 (1); 5-14 y, 61.2 (1.03 [0.89, 1.20]); ≥15 y, 40.0 (0.71 [0.53, 0.96]). From 2007-2016, malaria incidence decreased markedly in all age groups after malaria indoor insecticide residual spraying campaigns, and was highest in individuals 5-14 years old: <5y, 4.9 (1), 5-14 y, 7.9 (1.63 [1.20, 2,23]), ≥15y, 4.8 (1.01 [0.74, 1.37]). During the epidemic in 2017, incidence was again highest in the 5-14 year olds and was higher in the 5-14 year olds and ≥15 year olds than the <5 year olds: <5y, 2.7 (1); 5-14 y, 21.0 (7.71 [2.51, 38.52]); ≥15y, 13.0 (4.78 [1.58, 23.65]). The study data suggest that in areas with a prolonged decrease in malaria transmission, delayed acquisition of immunity and increased exposure in older children and adults may lead to high malaria incidence in these groups during epidemics.

Malaria is a parasitic disease widely distributed in tropical and subtropical areas of the world. The appearance of malaria cases is determined by multiple factors including changes in land use, and climatic and environmental variables, which are key factors contributing to the prevalence and transmission of the disease. Remote sensing allows for the integrated analysis of vector-borne diseases for the purposes of disease management and control. The aim of the present research was to determine whether there is a relationship between the emergence and abundance of malaria cases and changes in land use, and, in climatic/environmental variables provided by remote sensing in San Ramón de la Nueva Orán (northwestern Salta, Argentina). Random Effect Poisson Regression was used to analyze the relationships. The emergence of malaria cases was related to decreases in piedmont rainforest of the Yungas Ecoregion, and increases both in Maximum Normalized Difference Vegetation Index (NDVI) and in mean minimum temperature and relative humidity. These results were expected since environmental change derived from agriculture-driven deforestation together with climate change are likely factors driving transmission of this disease by affecting the biology and ecology of both vectors and malaria parasites.

CONTRIBUTION OF ASYMPTOMATIC CARRIAGE AND IMPORTED MALARIA TO SUSTAINED RESIDUAL TRANSMISSION IN KWAZULU-NATAL, SOUTH AFRICA: A PROVINCE ON THE BRINK OF ELIMINATING MALARIA

Jaishree Raman[1], Laura Gast[2], Basil Brooke[1], Rajendra Maharaj[3], Givemore Munhenga[1], Power Tshikae[1], Vishan Lakan[3], Ryleen Balawanth[2], Craig Davies[2], Lindi Sangweni[4], Moses Mkhabela[4], Nompumelelo Zondo[4], Zuziwe Nyawo[4], Sipho Msimang[5], Rebecca Graffy[2], Bheki Qwabe[4], Devanand P. Moonasar[6]

[1]National Institute for Communicable Diseases, Johannesburg, South Africa, [2]Clinton Health Access Initiative, Pretoria, South Africa, [3]Medical Research Council, Durban, South Africa, [4]KwaZulu-Natal Provincial Department of Health, Jozini, South Africa, [5]KwaZulu-Natal Provincial Department of Health, Pietermaritzburg, South Africa, [6]National Department of Health; University of Pretoria, Pretoria, South Africa

KwaZulu-Natal (KZN), one of South Africa's three malaria endemic provinces, has made impressive progress in reducing local transmission since the country's last major malaria epidemic in 1999. With only 33 locally-acquired malaria cases reported during the 2016/2017 season, KZN appears to be on the brink of halting local transmission. In an attempt to accelerate the province towards malaria elimination a community-based malaria prevalence survey was undertaken to identify factors contributing to sustained residual malaria transmission. The two primary research questions addressed by the survey were determining the (1) contribution of a potential asymptomatic/subclinical reservoir and (2) dynamics of malaria importation by travelers or mobile and migrant populations to the sustained transmission. The survey consisted to two parts: a) an assessment of malaria prevalence, malaria knowledge and recent travel among 3 000 individuals at 1 400 randomly selected, GPS-located households within areas identified as *Foci* of transmission, as well as 1 000 individuals visiting marketplaces along the border between KZN and Mozambique; and b) determining the prevalence and distribution of malaria vectors within the identified *Foci* of transmission. All consenting participants were tested for malaria by standard falciparum-specific rapid diagnostic test (RDT, First Response®) and highly-sensitive falciparum-specific RDT (Alere®), with filter-paper dried blood spots collected for downstream molecular analysis. Specific sources, sinks and trends in importation were evaluated by analysis of the participant travel history. Of the population surveyed, less than 2% (n=69) were found to be malaria positive by RDT. Interestingly no discordant results between the two different RDT brands being assessed were observed. All RDT-malaria-positive individuals were subclinical and reported recent travel to Mozambique. Nearly all (n=65) of the malaria-positive individuals detected were diagnosed at border markets. Data from this survey suggests local transmission in KZN is being seeded by malaria infections, primarily imported from Mozambique.

TRANSCRIPTOME ANALYSIS BASED DETECTION OF *PLASMODIUM FALCIPARUM* DEVELOPMENT IN *ANOPHELES STEPHENSI* MOSQUITOES

Miranda Oakley[1], Nitin Verma[1], Timothy Myers[2], Hong Zheng[1], Emily Locke[3], Merribeth Morin[3], Abhai Tripathi[4], Godfree Mlambo[4], Sanjai Kumar[1]

[1]Food and Drug Administration, Silver Spring, MD, United States, [2]National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [3]PATH's Malaria Vaccine Initiative, Washington, DC, United States, [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

The *Plasmodium* life cycle within the *Anopheles* mosquito includes the gamete, zygote, motile ookinete, and the oocyst stage that supports sporogony and sporozoite formation. Currently, circumsporozoite protein (CSP) is the only marker used for detection of *P. falciparum* infection in mosquitoes. However, CSP is detectable only after day 7 post-infection. To identify novel *Plasmodium* biomarkers that can be used to develop a detection assay for assessment of *P. falciparum* infection in mosquitoes throughout the development cycle of the parasite within the mosquito, we mapped the *P. falciparum* transcriptome as the parasite progresses through the oocyst stage of development on days 2, 4, 6, and 8 post-*P. falciparum* infectious blood meal. Using this genomics approach, we identified 212 novel transmission stage biomarkers including genes that are developmentally expressed at a single time point and genes that are pan-developmentally expressed at all four time points in *P. falciparum* oocysts. Validation of a small subset of genes at the transcriptional and translational level resulted in identification of a signature of proteins that can detect parasites within the mosquito as early as day 2 post-infectious blood meal and can be used to distinguish early versus late stage *P. falciparum* oocyst development in the mosquito. Our results open the prospect to develop a non-CSP based Western blot assay for detection of *P. falciparum* infection in mosquitoes and evaluate the effect of intervention measures on malaria transmission in an endemic setting.

The pathophysiological basis of *Plasmodium falciparum*-induced severe malarial anemia [(SMA, hemoglobin (Hb)<5.0 gdL^{-1} with any density parasitemia)] is multigenic - both host and parasite genetic factors contribute to the pathogenic spectrum. Transcription factors regulate cellular processes, including immunity. Nuclear factor kappa B (NFκB) and its inhibitor (IκB) are important in infectious and autoimmune diseases through their control over cellular processes. However, the effects of promoter polymorphisms within *NFκB1* and *NFκBIA* (an IκB gene) on susceptibility to SMA remain unreported. We tested the hypothesis that promoter polymorphisms in *NFκB1* and *NFκBIA* alter susceptibility to SMA in pediatric populations in holoendemic *P. falciparum* transmission regions. Genotyping was performed using TaqMan® assays, while gene expression analysis measured using qPCR. Logistic regression analyses (controlling for potential confounders) were used to determine the relationship between promoter polymorphisms in *NFκB1* (rs747559, G-8079A and rs980455, C-3297T) and *NFκBIA* (rs2233406, G-826A and rs2233409 G-310A), and susceptibility to SMA in children with malaria children (n=1,026; age=6-36 months). Results demonstrate that combined genotypes: *NFκB1*-8079AA/*NFκBIA*-826GA (OR=2.31, 95%CI: 1.30-4.08, *P*=0.004), *NFκB1*-3279TT/*NFκBIA*-826GA (OR=2.77, 95%CI: 1.10-6.97, *P*=0.031), and *NFκB1*-3297TT/*NFκBIA*-310GG (OR=2.10, 95%CI: 1.32-4.10, *P*=0.002) were associated with increased susceptibility to SMA. In addition, *NFκB1*-3279CC/*NFκBIA*-826GG (OR=0.69, 95%CI: 0.48-0.96, *P*=0.033) and *NFκB1*-3297CC/*NFκBIA*-310GG (OR=0.64, 95%CI: 0.44-0.92, *P*=0.016) combinations were associated with protection against SMA. *NFκBIA* expression levels were 1.6-fold higher in SMA; [mean (SEM)]; [3.37 (± 0.34), n=28] vs. non-SMA; [2.18 (± 0.46) n=28, *P*=0.045]. Results presented here demonstrate that promoter polymorphisms within NFκB/IκB gene pathways influence multigenic diseases, such as childhood SMA.

USING AMPLICON DEEP-SEQUENCING TO DETERMINE THE ETIOLOGY OF RESIDUAL ASYMPTOMATIC PARASITEMIA FOLLOWING HIGHLY EFFECTIVE INDOOR RESIDUAL SPRAYING IN A PREVIOUSLY HIGH TRANSMISSION SETTING IN UGANDA

Jessica Briggs[1], Joaniter Nankabirwa[2], John Rek[3], Emmanuel Arinaitwe[4], Grant Dorsey[1], Isabel Rodriguez-Barraquer[1], Moses Kamya[2], Bryan Greenhouse[1]

[1]University of California San Francisco, San Francisco, CA, United States, [2]Makerere University, Kampala, Uganda, [3]Infectious Diseases Research Collaboration, Nagongera, Uganda, [4]Infectious Diseases Research Collaboration, Kampala, Uganda

Currently there is limited understanding of to what degree asymptomatic infections with malaria parasites represent persistent infections of long duration vs. new infections from ongoing low-level transmission or importation. Characterizing the reservoir of asymptomatic parasitemia that persists following effective indoor residual spraying (IRS) is imperative to inform additional interventions needed for durable malaria control and eventual elimination. Data and samples come from a cohort of children and adults followed in Nagongera, Uganda from Oct 2011 to June 2017. Three rounds of IRS were conducted during this time, starting in Dec 2014. Active surveillance for parasitemia was conducted using both smear microscopy and loop mediated isothermal amplification (LAMP) to assess for submicroscopic parasitemia on all participants every 3 months from Aug 2011 to June 2017. In this study, we will extract DNA from RBC pellets collected from all participants with microscopic or sub-microscopic parasitemia, starting 6 months before IRS started (May 2014) and continuing through June 2017. This will include approximately 2000 samples from 94 patients that have at least 2 episodes of parasitemia recorded after the third round of IRS. We will then utilize an amplicon-based deep sequencing method targeting a highly variable (He=0.94) region of *P. falciparum* apical membrane antigen 1 (AMA-1) to genotype parasite clones present in these individuals at every time point. Persistent infection will be defined as a distinct clone being present in that participant for at least 6 months (i.e., detection of the same haplotype for at least 6 months), whereas new infections will be defined as those present for less than 6 months. Each infection detected will be defined as a binary variable (persistent vs. new), and we will determine what proportion of infections are persistent and how this changes over time, starting in Dec 2014. We will use generalized estimating equations to account for repeated measures within each participant and hypothesize that after 3 rounds of IRS, the majority of the parasite reservoir consists of persistent infections.

Plasmodium falciparum populations can differ greatly in genetic composition and extent of genetic diversity, resulting in significant population structure between and within geographic regions. While diversity between geographic regions is well documented, few studies have examined how parasite populations change over time in a given location. Characterization of these temporal dynamics might inform predictions or measures of the success of interventions, including antimalarial drug use and vaccines. To address this knowledge gap, 164 samples from a single village in Mali (collected in 2002 and 2010) and from southern Malawi (collected in 2007-2008 and 2016) underwent whole-genome sequencing, and the evolution of parasite populations was investigated using biallelic SNPs and indels. Regions of the genome with significant change in allele frequencies across timepoints were identified, with patterns congruent with positive selective pressure. Loci associated with resistance to antimalarial drugs, such as chloroquine and sulfadoxine-pyrimethamine, showed distinct signs of positive selection at one or more timepoints, highlighting the ability of population genetic analyses of field samples to detect the impact of public health interventions (such as changes in drug policy). Cross-population extended haplotype homozygosity tests identified genomic regions in both Mali and Malawi with evidence of selective sweeps; some of these selection signals were common to both geographic regions, and some have previously been identified in genome-wide association studies of artemisinin resistance in Southeast Asia. A region on chromosome 14 with signs of a selective sweep was also near a window with high F_{ST} containing a protein kinase. Finally, while many genes encoding antigens were under strong balancing selection, there was little evidence that allele frequencies at these loci (including leading pre-erythrocytic vaccines candidates) changed during the study period. These data provide a baseline of allele frequency changes against which the selective effects of public health interventions can be measured as they are deployed.

[1]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]Center for the Evaluation of Antimalarial Drugs and Vaccines, Tropical Medicine Research / Instituto Conmemorativo Gorgas de Estudios de la Salud, Panamá, Panama, [3]Eli and Edythe L. Broad Institute of MIT and Harvard, Boston, MA, United States, [4]University of Glasgow, Glasgow, United Kingdom

Malaria incidence in Panama has increased in recent years (~500 cases in 2010 to ~900 cases in 2016), despite elimination efforts, with the majority of cases caused by *Plasmodium vivax*. Notwithstanding the increase in cases, overall prevalence remains low (less than 1 case per 1000 persons). Genome sequencing of *P. vivax* parasites can inform epidemiology, population structure,and patterns of drug resistance. However, it can be difficult to sequence *Plasmodium* genomic DNA from patient blood samples due to the predominance of host DNA. Selective whole genome sequencing (SWGA) mitigates this problem by priming a highly processive polymerase from motifs that are common in the target genome and rare in the background gist genome. We used SWGA to sequence 60 *P. vivax* samples from Panama to gain insight into the population structure and transmission dynamics of the parasite, and 39 yielded usable sequencing data. Samples having a parasitemia greater than 120 parasites/ul exhibited at least 3X mean coverage at variant sites. There was variance in coverage across the genome, with the subtelomeres exhibiting low coverage across all samples. All of the successfully sequenced samples appeared monoclonal on the basis of low heterozygosity and allele balance. We observed low differentiation of parasites among districts via identity by state-based clustering and principal component analysis, and samples did not exhibit structure with respect to their position north or south of the Panama canal. More than half of the samples exhibited high genetic similarity to each other, with a small cluster of distinct samples in the Chepigana district. This suggests overall low genetic diversity, with distinct subpopulations driven by clonal transmission. We also used identity by descent (IBD) to explore patterns of recent common ancestry among the samples. This analysis confirmed the low haplotypic diversity in this parasite population and clarified spatial and temporal patterns of parasite relatedness resulting from transmission history. This work illustrates how SWGA data and IBD analysis can inform malaria epidemiology in low transmission settings.

GENOME-WIDE DIFFERENCES IN *PLASMODIUM FALCIPARUM* PARASITES IN MALAWIAN CHILDREN AND ADULTS

Zalak Shah[1], Kara Moser[1], Matthew Adams[1], Andrea Buchwald[1], Karl Seydel[2], Don Mathanga[3], David Serre[1], Miriam K. Laufer[1], Joana C. Silva[1], Shannon Takala-Harrison[1]

[1]University of Maryland School of Medicine, Baltimore, MD, United States, [2]Michigan State University College of Osteopathic Medicine, East Lansing, MI, United States, [3]University of Malawi College of Medicine, Blantyre, Malawi

After repeated *P. falciparum* infections, individuals in highly endemic regions acquire clinical immunity to malaria. This immunity is associated with increasing exposure and age. However, which loci or combination of loci are important in determining acquired immunity is not completely understood. Here we take a genomic approach to identify loci that may be involved in acquired immunity to malaria by examining parasite genomes collected from children and adults participating in a longitudinal cohort study in southern Malawi. Assuming adults have acquired immunity to most common antigenic variants in the parasite population, we hypothesize that parasites in adults will be distinct from parasites in children at loci related to acquired immunity. We also hypothesize that parasites in individuals' consecutive clinical infections will be more different from each other, compared to random infections from different individuals, at loci contributing to acquired immunity. We performed whole-genome sequencing on 212 parasite isolates from 95 individuals, after enriching for parasite DNA using selective whole genome amplification. F_{ST} was used to estimate differentiation between infecting parasites from children and adults and statistical significance was assessed by permutations. Preliminary results indicate several significant differences in parasites that cause infections in adults compared to children. These highly differentiated genes include pre-erythrocytic and erythrocytic vaccine target antigens such as RH2b, CLAG8 and SIAP2 (p-value < 0.001). Some of these genes have been previously shown to be under balancing selection. We will also present results on differences between parasites that cause consecutive symptomatic infections compared to differences within parasites in the population, as well as variants associated with symptomatic infection in adults. This whole-genome approach in the context of a longitudinal

study of different age groups may identify loci for further investigation as potential vaccine candidates and provide insights into mechanisms of acquired immunity and antigenic escape.

POLYIBD: INFERRING IDENTITY BY DESCENT FROM COMPLEX, POLYCLONAL INFECTIONS

Nicholas F. Brazeau[1], Aimee R. Taylor[2], Jonathan J. Juliano[3], Steven R. Meshnick[1], Robert Verity[4]

[1]University of North Carolina Gillings School of Global Public Health, Chapel Hill, NC, United States, [2]Infectious Disease and Microbiome Program, Broad Institute, Cambridge, MA, United States, [3]University of North Carolina School of Medicine, Chapel Hill, NC, United States, [4]Medical Research Council Centre for Outbreak Analysis & Modelling, Imperial College London, London, United Kingdom

Unraveling the genetic relatedness between malaria subpopulations can be leveraged to better understand how drug-resistant malaria parasites evolve and spread through time and space. Traditionally, genetic relatedness and population structure measures have been determined using a combination of F-statistics (i.e. Fst) or grade-of-membership models, such as STRUCTURE. However, these measures often do not account for multiplicity of infection (MOI), where a single individual can be infected with several distinct malaria genotypes. Recent evidence has suggested that models accounting for MOI and patterns of identity by descent (IBD) may provide additional power to resolve genetic relatedness and population structure at a fine-scale. Here, we present polyIBD which extends two recent programs: hmmIBD and isoRelate, and calculates the extent of IBD between isolates of any MOI. An extension of the existing software was needed, as in high-transmission areas, MOI estimates are frequently greater than two. polyIBD is a first-order, multilevel hidden Markov Model that uses a Markov chain Monte Carlo approach to infer parameters of genetic relatedness, recombination rate, and MOI. In addition, it is currently being extended to account for within sample relatedness (F_{ws}). Preliminary data indicates that we can reliably detect genetic relatedness in samples with MOIs of three over a full range (0.0-1.0) of IBD sharing (Pearson's Correlation, $r = 0.90$, $p < 0.01$). Currently, we are validating the model with the MalariaGen genetic cross and Pf3K datasets. polyIBD may help us better understand malaria population structure in high transmission countries within Sub-Saharan Africa and elsewhere.

1055

DRUG RESISTANCE AND POPULATION STRUCTURE OF *PLASMODIUM FALCIPARUM* ACROSS THE DEMOCRATIC REPUBLIC OF CONGO USING HIGHLY MULTIPLEXED PANEL OF THOUSANDS OF MOLECULAR INVERSION PROBES

Ozkan Aydemir[1], Nicholas Brazeau[2], Robert Verity[3], Patrick Marsh[1], Molly Deutsch-Feldman[2], Nicholas Hathaway[1], Travis Fulton[2], Melchior Mwandagalirwa[4], Antoinette Tshefu[4], Steve Meshnick[2], Jonathan Juliano[2], Jeffrey Bailey[1]

Understanding the drivers of the spread of malaria parasites and drug resistance across space and time is needed. These drivers can be elucidated using genetic tools. Here, we report novel molecular inversion probes (MIPs) allowing the rapid and cost-effective targeting of all major drug resistance mutations and 1800 moderate-frequency SNPs including a subset selected for high Fst values between countries in Africa. MIPs were used to genotype *Plasmodium falciparum* infections of over 1000 individuals from the 2013-14 Demographic and Health Survey conducted in the Democratic Republic of the Congo (DRC). Analysis of spatial structure suggests that parasites within the DRC form a single population with major geographic differentiation occurring from north to south suggesting decreased gene flow. A second component of spatial structure correlated with SNPs adjacent to drug resistance loci. Among drug resistance mutations, pyrimethamine resistance mutations in pfdhfr-ts are ubiquitous across the country while sulfadoxine resistance markers in dihydropteroate synthase (pfdhps) show the most marked spatial structure with apparent entry and spread from Eastern borders for both the double mutation and likely more recently the triple mutation. Pfcrt mutations show high prevalence in east and west while remaining low in north and south DRC. Pfcrt mutations also show an apparent selective disadvantage where their frequency within overall parasite population (30%) is markedly lower than their prevalence (51%) in infections. Overall, these findings suggest that parasites in DRC, while relatively panmictic, show identifiable patterns of variation that can define geographic origin. Drug resistance mutations appear to be a major perturbation in the population structure. Moreover, highly-multiplexed targeted sequencing using MIPs emerges as a cost effective method for elucidating pathogen genetics and drug resistance across entire countries and regions.

PLASMODIUM VIVAX INFECTION IN A GOLD-MINING AREA SITUATED IN THE BRAZILIAN AMAZON REGION: IMMUNOLOGICAL AND GENETICS CLUES

Tamirys P. Pimenta[1], Rafaele P. Oliveira[2], Thais H. Monteiro[3], Felipe B. Freitas[2], Aline C. Souza[2], Maria I. Jesus[2], Ana P. Rodrigues[2], Luana N. Costa-Lima[2], Andrea R. Baptista[4], Martin J. Enk[2], Ana M. Ventura[2], Edivaldo H. Oliveira[2], **Ricardo L. Machado**[4]

[1]Universidade Federal do Para, Belém, Brazil, [2]Instituto Evandro Chagas, Ananindeua, Brazil, [3]Universidade Federal do Pará, Belém, Brazil, [4]Universidade Federal Fluminense, Niteroi, Brazil

The endemic areas of malaria in Brazil are virtually restricted to the Amazon Region, but the distribution of the disease is not uniform. Among the Amazonian municipalities, Itaituba, in Para state, a gold-mining area in the Brazilian Amazon Region, reported the largest number of malaria cases in 2016 caused by *P. vivax*. We assessed the immunological aspects, genetic alterations related to CNVs that could lead to phenotypic alterations, as well the presence of polymorphisms in cytokine genes and their association with the infection. From a total of 279 individuals, the individual selections were performed. Six SNPs in four IL-6, IL-10, TNF-α and IFN-γ genes were determined; blood cell count was conducted on automatic analyzer; plasmatic cytokines were quantified by flow cytometry; density parasite was estimated by thick blood films with confirmation by nested-PCR; the CNVs was estimated by aCGH and association between copy number and parasite load, mean number of clinical infections and gender was assessed. Significant increase in the IL-6 and IL-10 levels in both malaria groups; the primary malaria patients displayed the highest significant IFN-γ levels; recurrent malaria patients displayed the highest significant TNF-α; malaria infection demonstrated correlation between parasite density and TNF-α, IL-6 and IL-10 levels; production of IL-10 was higher in the presence of *IL10*GCC/GCC haplotype; IFN-γ levels were correlated with previous malaria episodes; a total of 112 amplified genes and 12 deleted genes were observed and the CNVs found no included any gene related to receptors or vivax malaria resistance factors; there were no statistically significant correlations among clinical and pathological data and the presence of CNVs in the patients studied. This study provides preliminary data on Plasmodium-host interactions in an endemic area of gold-mining area and describes the quantitative changes and SNPs in the human genome in *P. vivax* infection.

1057

INVESTIGATING THE SELECTION OF ARTEMISININ RESISTANCE AS THE BACKGROUND OF EVOLVING PFS47 LOCUS

Ankit Dwivedi[1], Kara A. Moser[1], Alvaro Molina-Cruz[2], Carolina Barillas-Mury[2], Joana C. Silva[1]

[1]Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD, United States, [2]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Plasmodium falciparum (Pf) gene Pfs47 mediates evasion of the mosquito complement-like immune system, enabling parasite survival and transmission. Adaptation to local mosquito populations or different species has led to genetic differentiation at the Pfs47 locus among Pf populations. Pfs47 is encoded in chromosome 13, ~160 Kb downstream from kelch13 (K13), primary determinant of resistance to artemisinin (ART). Given the strength of selective pressure on both phenotypes, and the physical linkage between the two loci, it has been hypothesized that the fitness of this genomic region is determined by both loci, which might be in linkage disequilibrium with each other. We analyzed ~400 samples from five malaria-endemic regions, Peru, Brazil, Mali, Malawi and Cambodia. These regions differ in malaria transmission (highest in Africa), in the frequency of ART-resistance (high in Cambodia and low elsewhere), and in the number of mosquito species that transmit Pf (lowest in Africa). As expected, there is a high degree of genetic differentiation at the Pfs47 locus among geographic locations, with FST>0.3 in all pairwise comparisons except between E and W Africa. FST at Pfs47 is an order of magnitude higher than in flanking regions, consistent with a direct role of Pfs47 to population differentiation. Genetic diversity in Pfs47, as measured by nucleotide and haplotype diversity, is highest in Africa, and reflects ancient, neutral polymorphism. In contrast, the Pfs47 locus in Cambodia shows signs of recent positive selection, and significantly lower genetic diversity than seen in Africa, congruent with recent selective sweep(s). We will discuss the distribution of Pfs47 haplotypes among Cambodian Pf subpopulations, potential linkage between K13 and Pfs47 haplotypes, and their relationship to the genetic diversity in Pfs47 prior to the emergence of ART resistance, to determine the extent to which genetic diversity in one locus impacts the other. Most importantly, the low genetic diversity at the Pfs47 locus in Cambodia may limit the spread of ART-resistant parasites to continents with evolutionary distant anopheline species.

THE GENETIC DIVERSITY OF *PLASMODIUM FALCIPARUM* IN GHANA

Maame Esi Dawson-Amoah[1], Yaw A. Afrane[1], Linda E. Amoah[2]

[1]University of Ghana, Accra, Ghana, [2]Noguchi Memorial Institute of Medical Research, Accra, Ghana

In malaria-endemic regions, many individuals experience asymptomatic *Plasmodium* infections, particularly older children due to their level of immunity. Transmission from humans to mosquitoes requires blood meals containing gametocytes. Gametocytes often occur at submicroscopic densities, challenging measurement in human populations. The population structure of the causative agents of human malaria, *Plasmodium* species including the most prevalent *Plasmodium falciparum*, depends on the local epidemiological and demographic situations, such as the incidence of infected people, the vector transmission intensity and migration of inhabitants. In this regard, genotyping malaria parasites to evaluate the diversity in different transmission settings is essential to understand the distribution and dynamics of parasite populations. The aim of this study is to determine the *Plasmodium falciparum* genetic diversity and population structure in regions of varying patterns of malaria transmission in Ghana. Understanding the *P. falciparum* population structure variations across the country provide new insights to guide malaria control strategies. A cross sectional study was conducted in five endemic sites. These sites were picked based on the different ecological zones of Ghana. Finger prick blood was collected from 1153 school children aged between 4 years and 12 years during the dry and rainy seasons of 2017. The school children were from five study sites in Ghana with different transmission settings. Malaria parasites were detected by light microscopy (LM) and nested polymerase chain reaction (nPCR). Characterization of *P. falciparum* was employed using 12 microsatellite markers. Microscopy results estimated that 16.65% (192/1153) of the population carried gametocytes. Findings from this study will attain data on the genetic diversity of *P. falciparum* in Ghana. The study will also determine the prevalence of asymptomatic malaria infections in the population. In addition, this study will also determine the proportion of sub microscopic infection carriage among asymptomatic people in Ghana.

NOVEL *IN SILICO* READ CAPTURE APPROACH OF WGS DATA FROM CLINICAL SAMPLES REVEALS TWO VAR2CSA HAPLOTYPE CLASSES RESPONSIBLE FOR MOST ANTIGENIC DIVERSITY

Antoine Dara[1], Mark A. Travassos[1], Abdoulaye Djimde[2], Christopher V. Plowe[3], Miriam K. Laufer[1], Joana C. Silva[4]

[1]Division of Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, [2]Malaria Research and Training Center, University of Science, Techniques and Technologies of Bamako, Bamako, Mali, [3]Duke Global Health Institute, Duke University, Durham, NC, United States, [4]Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD, United States

Pregnancy-associated malaria (PAM) has tremendous negative consequences for both fetuses and mothers in malaria-endemic settings. Sequestration of *Plasmodium falciparum* in the placenta, the hallmark of PAM pathophysiology, is mediated by VAR2CSA, a member *of P. falciparum* erythrocyte membrane protein-1 family. VAR2CSA induces protective immunity following successive malaria-exposed pregnancies, supporting its choice as a vaccine candidate against placental malaria. However, development of a VAR2CSA-based vaccine has been hampered by extensive polymorphism of the gene encoding this protein. Because immunity to placental malaria is known to develop rapidly after the first pregnancy, we hypothesize that at most a few major antigenic variant classes of VAR2CSA exist. Here, we developed a novel approach to identify *var2csa* sequence reads from any whole genome sequence dataset, using as a reference a collection of 30 highly diverse, full-length *var2csa* publicly available sequences and others we have generated ourselves from a geographically diverse collection of *P. falciparum* strains. Using this approach, we reconstructed full-length *var2csa* from approximately 200 clinical samples. As expected, we observe high genetic diversity across samples with average amino acid sequence similarity ~75%. However, our analysis reveals that despite the extensive diversity of global *var2csa* sequences, sequences can be clustered into two main haplotype groups, each characterized by a unique 32 amino acid residue signature and two additional minor clusters. Our results suggest that a broadly protective vaccine to prevent placental malaria could include a limited number of representative strains.

B CELL MEDIATED IMMUNE RESPONSES AGAINST *PLASMODIUM* INFECTIONS ARE MODULATED BY THE T-BET TRANSCRIPTION FACTOR

Munir Akkaya, Billur Akkaya, Patrick W. Sheehan, Clare K. Cimperman, Brandon P. Theall, Mirna Y. Pena, Susan K. Pierce

National Institutes of Health, Rockville, MD, United States

Malaria is a global health concern which affects over 200 million individuals worldwide. Although immune system rapidly responds to *Plasmodium* infection with specific antibodies, natural antibodies fail to

establish long term protection often leading to repetitive infections and chronicity. Recent studies showed that in chronic malaria setting both B cells and T cells induce T-bet transcription factor expression yet it is unclear whether this is a host defense strategy or a consequence of disease. Here we show in T-bet zsgreen reporter mice that, infection with *Plasmodium chabaudi* leads to gradual increases in T-bet expression of various B cell subsets including very high levels in germinal center B cells. Furthermore, parallel infection of WT and T-bet KO mice showed that T-bet deficiency increased IgM and decreased IgG response to *Plasmodium chabaudi* which, in turn, led to the failure of KO mice to clear the infection. In line with this observation, using bone marrow chimeric mice reconstituted with 1:1 ratio of T-bet KO and WT bone marrow cells, we showed that while the reconstitution is normal for both cells in steady state, upon infection Plasma cell compartment is dominated with WT cells. Altogether we conclude that T-bet expression in germinal center B cells is critical in inducing isotype switching and plasma cell generation in *Plasmodium* infection.

EXPRESSION AND REGULATION OF ACTIVATION-INDUCED CYTIDINE DEAMINASE AID MRNA IN SYMPTOMATIC AND ASYMPTOMATIC *PLASMODIUM FALCIPARUM* INFECTED CHILDREN

Reuben Ayivor-Djanie[1], Bismarck Dinko[2], Kwadwo A. Kusi[3], Gordon A. Awandare[1]

[1]WACCBIP, University of Ghana, Legon, Accra, Ghana, [2]Department of Biomedical Sciences, SBBS, University of Health and Allied Sciences, Ho, Ghana, [3]Noguchi Memorial Institute for Medical Research, University of Ghana, Legon, Accra, Ghana

Activation-Induced cytidine Deaminase, (AID), initiates somatic hypermutation and class switch recombination in B-lymphocytes. Despite this essential physiological activity of the protein, it mutates other genes in addition to the Ig gene when it is aberrantly expressed. Recently, AID has been postulated to be the molecular link between infection with *Plasmodium falciparum* the occurrence of the endemic form of Burkitt's lymphoma. Although *P. falciparum* is reported to induce AID expression, it is not known how the expression of the protein is regulated in response to *P. falciparum* infection. The aim of this work was to investigate how *P. falciparum* infection affects the expression levels of AID mRNA transcripts. We therefore measured the levels of AID mRNA transcripts in PBMCs isolated from the blood of asymptomatic and symptomatic *P. falciparum* infected children. We also used nested PCR to determine the splice variants of AID mRNA expressed in these PBMCs. We observed significantly high levels of AID mRNA in *P. falciparum* infected children with clinical symptoms compared to asymptomatic infected children. Splice variant nested PCR also revealed more splice variants of AID mRNA transcripts in the PBMCs of symptomatic children as compared to asymptomatic and non-infected children. AID mRNA levels did not vary significantly between healthy un-infected and *P. falciparum* infected asymptomatic children. In addition, infection with EBV did not affect the expression of AID mRNA in healthy un-infected and infected asymptomatic children. The findings so far suggest that a factor in symptomatic *P. falciparum* infected children may be involved in the upregulation of AID mRNA expression.

ACUTE EPSTEIN BARR VIRUS INFECTION IS A RISK FACTOR FOR THE DEVELOPMENT OF NON-CEREBRAL SEVERE MALARIA

Palmer Masumbe Netongo[1], Palmer Masumbe Netongo[2], Balotin Fogang[3], Aarti Aarti Jain[4], Patrice Mimche[1], Carole Eboumbou[3], Phillip Felgner[4], Huw Davies[4], Samuel H. Speck[5], Lawrence Ayong[3], Tracey J. Lamb[1]

[1]Department of Pathology, University of Utah, Salt Lake City, UT, United States, [2]The Department of Biochemistry and The Biotechnology Center, University of Yaounde I, Yaounde, Cameroon, [3]Centre du Pasteur Cameroon, Yaounde, Cameroon, Yaounde, Cameroon, [4]Department of Medicine - Div. of Infectious Diseases, University of California, Irvine, CA, United States, [5]Department of Microbiology and Immunology, Emory University School of Medicine, and Emory Vaccine Center, Emory University, Atlanta, GA, United States

Infants in malaria-endemic areas are often disproportionately affected by the symptoms of malaria with many ending up hospitalized with severe symptoms of this disease. It is during the first few years of life that these infants also become co-infected with Epstein Barr Virus. It has long been appreciated that interactions occur between EBV and *Plasmodium falciparum* infections that can lead to the loss of immune mechanisms preserving viral latency and the development of an EBV-related malignancy known as endemic Burkitt's lymphoma (eBL). However, very little is known regarding the potential impact of primary EBV infection on the severity of *P. falciparum* infections. Although acute EBV infection is generally asymptomatic in young children, virus-induced humoral immune deficiencies have however been observed towards unrelated antigens. The immunosuppressive effects of acute lytic EBV infection have been reported to last for at least 4 weeks. We tested the hypothesis that infants with acute EBV infection had reduced anti-malarial antibody titres compared to their uninfected or latently-infected peers. We also tested the hypothesis that children with acute EBV infection were more likely to develop severe malarial symptoms. We conducted serological analysis to classify the EBV infection status of 240 infants (four age groups (0-12, 12-18, 18-24 months) in Yaounde, Cameroon. The total incidence of EBV-infected infants was 57.5% with acute or latent EBV infection in older infants. However there was no difference in the average age of those with uninfected with malaria compared with those experiencing uncomplicated or severe malaria. We found that children with acute EBV infection were more likely to have severe malaria compared to those with no EBV infection or latent EBV infection, irrespective of age. We then quantified the breadth of the antibody response against *P. falciparum* antigens using a protein microarray. Contrary to our hypothesis we found that antibody reactivity within the acute EBV group was higher than those who were uninfected with EBV or latently infected with EBV. The implications of these results will be discussed.

1063

LONG-LIVED MEMORY B CELL RESPONSE TO *PLASMODIUM VIVAX* DUFFY BINDING PROTEIN IN MALARIA LOW TRANSMISSION AREA

Siriruk Changrob[1], Amy M. McHenry[2], Myat Htut Nyunt[3], Jetsumon Sattabongkot[4], Eun-Taek Han[3], John H. Adams[5], Patchanee Chootong[1]

[1]Faculty of Medical Technology, Mahidol University, Nakhon Pathom, Thailand, [2]Department of Biological Sciences, Southwestern Adventist University, Keene, TX, United States, [3]Department of Medical Environmental Biology and Tropical Medicine, School of Medicine, Kangwon National University, Chuncheon, Gangwon-do, Republic of Korea, [4]Mahidol Vivax Research Unit, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [5]Department of Global Health, University of South Florida, Tampa, FL, United States

Very little known about the durability of antigen-specific memory B cells and antibody responses to malaria. The aim of this study was to analyze the longevity of antibody and memory B cell (MBC) response of promising vaccine candidate of blood-stage, Duffy Binding Protein region II (DBPII), in *P. vivax*-exposed individuals living in a malaria endemic area in southern Thailand. We found that anti-DBPII antibody increase during acute infection, but a majority of these responses were significantly decreased at 9 months post-infection. In sharp contrast, circulating DBPII-specific MBCs were stably maintained at least 3 years post-infection without re-exposure to infection. Phenotyping of MBCs subset showed the expansion of activated and atypical MBCs occur during *P. vivax* infection. Interestingly, the ratio between activated/atypical MBCs increased during recovery

from infection, increasing from 1:2 at acute phase to 1:3, 1:3 and 1:4 at 3-month, 9-month and 12-month post-infection, respectively. The alteration of activated/atypical MBC ratios appeared to be related to short-lived anti-DBPII antibody responses. To demonstrate which MBC subset that play a role in maintaining or regulating of efficient antibody responses to DBPII in naturally acquired *P. vivax*-infection, we generated fluorescent antigen tetramer for characterization of DBPII-specific MBC on the basis of the antigen specificity of their BCR. A better understanding of the function of activated/atypical MBC and their role in generating protective antibodies is important for developing an effective DBPII-based vaccine.

MEMORY B CELLS ARE REACTIVATED IN VACCINATED C57/BL6 MICE AFTER CHALLENGE WITH *PLASMODIUM BERGHEI*

Hayley Joseph[1], Qiao Ye Tan[1], Ramin Mazhari[1], Emily Eriksson[1], Louis Schofield[2]

[1]The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, [2]James Cook University, Townsville, Australia

Malaria continues to be a major global health burden, with more than 216 million cases in 2016. One challenge impeding elimination is the lack of understanding of B cell immunity in malaria and, furthermore, the lack of research tools to phenotype rare antigen specific B cells. The aim of this research was to develop a novel method for identifying carbohydrate-specific B cells and, by doing so, determine if a candidate carbohydrate-conjugated vaccine generated functional memory B cells that could reactivate upon challenge with *Plasmodium* parasites. The vaccine used was a synthetic glycosylphosphatidylinositol (GPI) conjugated to keyhole limpet haemocyanin (KLH). GPI is expressed freely on the membrane of the parasite or used as an anchor for important surface proteins. It is conserved across all *Plasmodium* species and lifecycle stages. In the current study, B cell immune kinetics were analysed after vaccinating C57/Bl6 mice subsequent to validating a flow cytometry probe that binds GPI-specific B cells. Mice were rested (10 weeks) and challenged with parasites or GPI-KLH (positive control). Kruskal-Wallis and paired t-tests were used to assess significance. Our innovative probe was able to detect GPI-specific class-switched memory B cells after vaccination. These functional cells reactivated and boosted when challenged with carbohydrate or parasites, albeit to a lesser degree with the latter. Additionally, priming B cell responses to GPI-KLH measured in naïve mice and previously *Plasmodium*-exposed mice did not significantly differ, indicating that prior infection did not have an irreversible detrimental effect on B cells. Our novel findings can contribute to the knowledge gap concerning B cell immunity in malaria, are clinically significant for the potential inclusion of carbohydrate conjugates in the malaria elimination agenda, and the novel cytometric technique is applicable for exploring other relevant epitopes for their role in antigen-specific B cell responses in malaria.

THE CD73$^+$ B-CELLS THAT ARE PROTECTIVE AGAINST *PLASMODIUM YOELII* (PYNL) ALSO EXPRESS IGM AND GRANZYME B.

Marcela Parra, Megan Weitner, Mustafa Akkoyunlu, Amy Amy, Sheldon Morris, Steven Derrick

Food and Drug Administration, Silver Spring, MD, United States

Despite the critical importance of humoral and B cell mediated immunity in protecting against malaria, the biological nature of anti-malaria B cell responses have not been fully delineated. Examining PD-L2, CD80 and CD73 marker expression on splenic B cells by flow cytometry, we previously showed that when compared to naïve mice, the frequencies of CD73$^+$ B cells increased from 6.1±0.3% at day 6 to 28.0 ±0.6% at day 13 post infection. CD73$^+$ B cell-frequencies (52.1±0.9%) continued to increase even when parasitemia levels had cleared at day 22 post infection. By day 55 post-infection, the frequency of CD73$^+$ B cells remained elevated (16.06±0.84) when compared to naïve mice (2.32±0.3). To determine whether CD73$^+$ B-cells from PyNL immune mice play a role in protection, we passively transferred immune CD73$^+$ or CD73$^-$ B cells from malaria recovered mice into naïve mice prior to challenge with PyNL and assessed parasitemia. Parasitemia levels were reduced 96.6% in mice that received immune CD73$^+$ B-cells (0.26±0.14%) compared to mice infected for the first time (12.58±0.14%). Interestingly, CD73$^-$ B cells from immune mice afforded only a modest reduction in parasitemia (8.8 ± 1.49%). Further characterization of immune CD73$^+$ B-cell population indicated that significant proportion of CD73$^+$ B cells were GrB$^+$ at day 13 post primary immunization. There was also an increase in the CD73$^+$GrB$^+$ population after a second infection. Four days after a secondary infection, CD73$^+$GrB$^+$ cells increased 3-fold as compared to 1 month post parasitemia clearance frequency (p= 0.0079), and 7-fold with respect to day 4 post primary PyNL infection (p=0.0079). Interestingly, 33.46% of the CD73$^+$ B cells also expressed IgM. In conclusion, we showed that passive transfer of immune CD73$^+$ B-cells conferred protection against a primary PyNL infection and that a significant fraction of these immune CD73$^+$ B cells expresses GrB and IgM.

RECOGNITION OF EXCRETED-SECRETED ANTIGENS OF *PLASMODIUM FALCIPARUM* BY IMMUNOBLOTTING

María E. Vásquez-Chasnamote[1], Rafael Saavedra-Langer[1], Jorge L. Marapara[2], Viviana V. Pinedo-Cancino[1]

[1]Natural Resources Research Center of the Amazon, CIRNA-UNAP, Iquitos, Peru, [2]Faculty of Biological Sciences, National University of the Peruvian Amazon (UNAP), Iquitos, Peru

In vitro cultures of *Plasmodium falciparum* (*Pf*) excrete-secrete into the culture medium a complex mixture of antigenic proteins also known as exoantigens, which provide the parasite with the necessary mechanisms to evade the host's immune system. The purpose of the present study was to partially characterize the analysis of antibody reactivity of malaria positive patients with different parasitic densities. Cultures of *Pf* strain 3D7 were synchronized with 35-65% Percoll and 5% D-sorbitol. The exoantigens were obtained from Albumax free cultures with parasitemias ≥20%, which were separated by SDS-PAGE electrophoresis and evaluated by immunoblotting, facing sera from malarial and non-malarial patients. Ten immunoreactive bands (148, 139, 124, 120, 116, 110, 72, 53, 18 and 12 kDa) were observed in malarial patients. The 72, 18 and 12 kDa proteins were present more frequently but were not related to the increase in parasite load. The 62, 57 and 28 kDa proteins showed reactivity with sera from non-malarial patients and other diseases such as Toxoplasmosis, Leishmaniosis, Herpes and serum from non-endemic area individuals. The recognition of immunoreactive bands opens up the possibility of optimizing the technique and evaluating purified antigens for the serological diagnosis of symptomatic and asymptomatic malaria.

IMPACT OF PREVIOUS MALARIA EXPOSURE ON HOST RESPONSES TO PLACENTAL MALARIA

Jennifer Howard[1], Robert Morrison[1], Omely Marte[1], Ankur Sharma[2], Lynn Lambert[1], Sachy Orr-Gonzalez[1], Michal Fried[1], Patrick Duffy[1]

[1]National Institute of Allergy and Infectious Diseases, Rockville, MD, United States, [2]University of Maryland School of Medicine, Baltimore, MD, United States

Plasmodium falciparum infected erythrocytes express VAR2CSA and bind chondroitin sulfate A (CSA) to sequester in the intervillous space of the placenta. Poor outcomes in placental malaria (PM) have been associated with the inflammatory response during chronic episodes of PM, which is characterized by a monocyte/macrophage-rich inflammatory infiltrate in the intervillous space. It has previously been postulated that the inflammatory engine of PM has features of a type III hypersensitivity reaction, in which antibody-antigen immune complexes activate the

complement pathway leading to a cytokine storm. We hypothesize that pre-existing immunity to malaria antigens is activated early in infection and contributes to triggering the subsequent inflammation. To assess the impact of the adaptive immune system and immune complexes in early PM immune response *in vivo*, we immuno-profiled placental blood from infected, primigravid Malian women by multi-colour flow cytometry and ELISA. Activated memory B cells, detected by flow cytometry, were found to be significantly increased in chronic (late), but not acute (early) PM infection. However, circulating immune complexes, as detected by ELISA, were already significantly increased in acute PM, suggesting an early role of pre-existing Abs in PM immune responses. The impact of previous non-PM malaria exposure is not feasible to study in human cohort studies, however *Aotus nancymaae* is a new world non-human primate which can be infected with *P. falciparum*. We are developing Aotus as a new model of PM. To address the impact of previous (non-PM) exposure to *P. falciparum* on immune responses during PM; naïve Aotus and Aotus with one previous infection, were allowed to become pregnant and infected with *P. falciparum*. Placental blood mononuclear cells were collected, and the extracted RNA sequenced and quantified. Differences in gene expression relating to immune activation was compared between the naïve and previously exposed groups, and will be presented. This study aims to provide a better understanding of the immune mechanisms which trigger pathological inflammation during PM.

A STRUCTURALLY DEFINED EPITOPE IN *PLASMODIUM VIVAX* PVDBP THAT MAY MEDIATE ANTIBODY CROSS-REACTIVITY TO SIMILAR EPITOPES IN VAR2CSA

Catherine J. Mitran[1], Aravindhan Ganesan[1], Sedami Gnidehou[2], Francis Ntumngia[3], John H. Adams[3], Khaled Barakat[1], Michael F. Good[4], Stephanie K. Yanow[1]

[1]University of Alberta, Edmonton, AB, Canada, [2]Campus Saint-Jean, Edmonton, AB, Canada, [3]University of South Florida, Tampa, FL, United States, [4]Griffith University, Gold Coast, Australia

Malaria remains one of the most important parasitic diseases in the world. Adherence to host ligands is a mechanism used by malaria parasites for essential functions such as invasion and evasion of the host immune system. Many of the parasite proteins that mediate adherence contain a structurally conserved Duffy binding-like (DBL) domain. The parasite protein PvDBP, which contains one DBL domain, mediates *P. vivax* merozoite invasion by binding to the Duffy Antigen Receptor for Chemokines (DARC) receptor on the red blood cell (RBC) surface. In pregnant women, *P. falciparum* parasites express VAR2CSA, which contains 6 DBL domains and mediates adherence to chondroitin sulphate A (CSA) in the placenta. We previously observed immunological cross-reactivity between the DBL domains of PvDBP and VAR2CSA in naturally exposed populations in Colombia. We then characterized a monoclonal antibody (mAb) raised against the DBL domain of PvDBP that cross-reacts with VAR2CSA, stains *P. falciparum* iRBCs that express VARCSA and blocks parasite adhesion to CSA *in vitro*. Here, we mapped the minimal epitope in PvDBP that is recognized by the mAb to a 40 amino acid sequence, called 'SD1', consistent with previous work based on site-directed mutagenesis of this region in PvDBP. We further characterized the epitope using synthetic peptides and molecular dynamic simulations. Our data suggest the epitope is likely conformational, containing a small alpha helix stabilized by two pairs of disulphide bonds and salt bridges. Based on homology modeling and published crystal structures, we then identified structurally similar SD1-like epitopes in several of the DBL domains in VAR2CSA. We are now evaluating the immunological dominance of these epitopes using polyclonal antibodies against PvDBP and VAR2CSA. We propose that SD1 in PvDBP is structurally conserved in VAR2CSA and mediates the cross-reactivity between PvDBP and VAR2CSA.

ACQUISITION OF INTRALEUKOCYTIC HEMOZOIN DOWNREGULATES *LAIR1* EXPRESSION AND LEUKOCYTE INHIBITORY SIGNALLING IN PEDIATRIC SEVERE MALARIAL ANEMIA

Angela O. Achieng[1], Bernard Guyah[2], Qiuying Cheng[3], Elly O. Munde[1], Caroline Ndege[3], Evans Raballah[4], Samuel B. Anyona[1], Collins Ouma[1], Ivy Foo-Hurwitz[3], John Ong'echa[5], Christophe G. Lambert[3], Prakasha Kempaiah[3], Douglas J. Perkins[3]

[1]Maseno University, Maseno, Kenya, [2]Department of Biomedical Sciences and Technology, School of Public Health and Community Development, Maseno, Kenya, [3]University of New Mexico, Albuquerque, NM, United States, [4]Masinde Muliro University of Science and Technology, Kakamega, Kenya, [5]KEMRI, Kisumu, Kenya

Severe malarial anemia (SMA) [hemoglobin (Hb)<5.0 g/dL, with any density parasitemia] is a multifactorial complication of malaria in children residing in *Plasmodium falciparum* holoendemic areas. To identify molecular pathways involved in SMA pathogenesis, we conducted whole transcriptome profiling in a discrete subset of "polarized" phenotypes: non-SMA and SMA (3-36 months) from Western Kenya. These experiments revealed that leukocyte-associated immunoglobulin like receptor 1 (LAIR1) transcripts were downregulated in SMA (-1.6 fold, P=0.0042). TaqMan® gene expression analysis in non-SMA (n=52) vs. SMA (n=52) confirmed downregulation of *LAIR1* (-3.0 fold, P=0.017) in severe

disease. *LAIR1* transcripts were also negatively correlated with hemozoin (*Pf*Hz) containing monocyte (PCM/μL) titres (r = -0.298, *P*=0.003). To further explore the relationship between LAIR1 transcripts, acquisition of intraleukocytic *Pf*Hz, and the subsequent impact on leukocyte signalling, cultured PBMCs from malaria-naïve donors were treated with physiological concentrations of *Pf*Hz (10 μg/mL) found in SMA. *Pf*Hz treatment suppressed LAIR1 transcript expression (-4.0 fold *P*<0.001) and inhibited LAIR1 signalling, i.e., decreased phosphorylation of LAIR1 (*P*<0.0001) and SH2-domain containing phosphatase-1 (SHP-1) (*P*<0.001). *Pf*Hz also induced NF-κB activation (*P*=0.004), and enhanced production of IL-6, IL-1β, and TNF-α (all *P*<0.0001). These novel findings reveal that LAIR1 expression is downregulated in children with SMA, and that phagocytosis of *Pf*Hz abrogates leukocyte signalling through the LAIR1 pathway.

1070

ELEVATED LEVELS OF CD4+CD45RA-CD62L+CD11A+ ARE ASSOCIATED WITH MALARIAL ANEMIA DISEASE SEVERITY IN KENYAN CHILDREN

Evans Raballah[1], Samuel B. Anyona[2], Prakasha Kempaiah[3], Collins Ouma[2], John M. Ong'echa[4], Douglas J. Perkins[3]

[1]Masinde Muliro University of Science and Technology, Kakamega, Kenya, [2]Maseno University, Maseno, Kenya, [3]University of New Mexico, Albuquerque, NM, United States, [4]KEMRI, Kisumu, Kenya

L-selectin (CD62L) attracts lymphocytes into secondary lymphoid organs. LFA-1 (CD11a) promotes emigration of lymphocytes from the blood and is upregulated on activated T cells. Since CD62L and CD11a are largely unexplored in malarial anemia, CD4+ T-cell populations were characterized in malaria-infected children (n=54; aged 12-36 months) with varying severities of anemia presenting at Siaya County Referral Hospital, a holoendemic *Plasmodium falciparum* transmission region. Complete hematological profiles and parasitemic indices were obtained. Parasitemic children were stratified based on hemoglobin (Hb): uncomplicated malaria (UM; Hb≥11.0 g/dL; n=12), mild malarial anemia (M/MA; Hb≥8.0<11.0 g/dL; n=22), and severe malarial anemia (SMA; Hb<6.0 g/dL; n=20). Peripheral blood was stained with anti-(CD3; CD4; CD45RA; CD11a; and CD62L) antibodies. Cells were then acquired using four-color FACSCalibur™ flow cytometer. The proportion of (CD4+ CD45RA-CD11a+) were comparable across the groups [median (IQR) UM, 98.16% (1.97); M/MA, 97.41% (2.71); SMA, 97.43% (2.69); *P*=0.422]. In addition, the proportions of (CD4+ CD45RA- CD62L+) were comparable across the groups [median (IQR) UM, 72.52% (11.90); M/MA, 76.88% (12.80); SMA, 77.33% (11.90); *P*=0.229]. However, the co-expression of CD11a and CD62L (CD4+ CD45RA- CD11a+ CD62L+) differed significantly across the groups [median (IQR) UM, 67.98% (5.96); M/MA, 75.46% (15.07); SMA, 72.17% (9.89); *P*=0.025]. Further analysis showed that both the M/MA (*P*=0.012) and SMA (*P*=0.040) groups had elevated levels of circulating CD4+ CD45RA- CD62L+ CD11a+ relative to the UM group. These results suggest that CD4+ T cells co-expressing CD11a and CD62L are associated with malaria severity, and may be important in the pathogenesis of SMA.

PROFILING OF PHENOTYPIC CHARACTERISTICS OF IMMUNE CELLS FOLLOWING MALARIA TREATMENT BY MASS CYTOMETRY

Sidney O. Ogolla[1], Connor Jackson[2], Daniel Kong[2], Ryan Baxter[2], Odada P. Sumba[3], Emmily Koech[3], Elena Hsieh[2], Rosemary Rochford[2]

[1]Kenya Medical Research Institute and University of Colorado, Anschutz Medical Campus, Kisumu, Kenya, [2]University of Colorado, Anschutz Medical Campus, Denver, CO, United States, [3]Kenya Medical Research Institute, Kisumu, Kenya

Plasmodium falciparum malaria infection results in a complex pattern of immune modulation. To understand how the host responds to malaria infection, we utilized mass cytometry (CyTOF , Cytometry by Time of Flight) to perform a comprehensive immune phenotypic analysis. Mass cytometry is a multiparameter analytical platform that enables simultaneous evaluation of up 42 cell markers per single-cell, thus providing in-depth analysis of immune cellular heterogeneity. We applied this platform together with computational algorithms and clinical data to comprehensively explore the phenotypic immune cellular heterogeneity in children with acute malaria and post-recovery (four weeks' post treatment with Artemether-Lumefantrine) samples. Whole blood samples from children with malaria infection were prospectively collected at acute and post recovery timepoints, and processed following RBC lysis, fixation and cryopreservation. The samples were then thawed, barcoded, pooled and stained using a cocktail of antibodies specific to 26 cell surface markers and 14 cytokines conjugated to elemental metal isotopes and analyzed on a Helios mass cytometer. The data was then uploaded to Cytobank where the software program viSNE was used to visualize the high dimensional single cell data. Unsupervised multivariate clustering analysis was also performed on the data using Cytofkit. Unsupervised gating strategy revealed a dramatic expansion of distinct monocyte cell populations during acute malaria as compared to recovery. Further analyses are ongoing to identify the cytokine patterns in the cell subsets present during acute malaria and following recovery. Our data demonstrate that CyTOF together with unsupervised clustering algorithms can comprehensively characterized multiple cell populations thus enabling extensive profiling of cellular subsets. Acute malaria causes a complex pattern of lymphocyte subset distribution. Novel cellular populations identified could drive hypothesis generation for further experiments.

A SELECTIVE LIQUID CHROMATOGRAPHY-MASS SPECTROMETRY METHOD FOR SIMULTANEOUS QUANTIFICATION OF ARTEMETHER, LUMEFANTRINE AND THEIR PRINCIPLE METABOLITES IN HUMAN PLASMA

Martin O. Ongas[1], Elizabeth Juma[2], Florence Oloo[3], Gilbert Kokwaro[4], Rashid Aman[5], Bernhards R. Ogutu[2]

[1]Centre for Research in Therapeutic Sciences, Strathmore University, Nairobi, Kenya, [2]Kenya Medical Research Institute (KEMRI), Nairobi, Kenya, [3]Technical University of Kenya, Nairobi, Kenya, [4]Institute of Health Management, Strathmore University, Nairobi, Kenya, [5]African Centre for Clinical Trials (ACCT), Nairobi, Kenya

Dosage regimens for antimalarials are often extrapolated from the non-pregnant population despite the fact that the pharmacokinetics (PK) of antimalarials are changed in pregnancy and even more so in pregnant women with malaria. Currently there is insufficient PK data of artemisinin based combination therapies in pregnancy to recommend any changes in the dosage regimen. Lower drug concentrations in pregnancy compared with non-pregnant populations increases the risks of therapeutic failure and sub-optimal concentrations can lead to selection of resistant parasites. A quantitative assessment of these antimalarials in plasma in the course of artemether-lumefantine treatment is essential in order to evaluate the bioavailability and pharmacokinetics of these co-formulated compounds and how their potent metabolites influence treatment outcome. We have developed and validated a sensitive, selective and reproducible reversed-phase high-performance liquid chromatography method coupled with electrospray ionization mass spectrometry for the simultaneous quantification of artemether (ART), dihydroartemisinin (DHA), lumefantrine (LUM) and desbutyl-lumefantrine (DBL) in human plasma. Mefloquine was used as an internal standard (IS). The analytes were extracted by protein precipitation procedure and separated on a reversed-phase Zorbax SB-Ciano column with a mobile phase composed of acetonitrile and 20mM aqueous ammonium formate containing 0.5% (v/v) formic acid. The assay response were linear ($r^2 \geq 0.9992$) over the range of 5-1500 ng/mL for ART/ DHA and 5-5,000 ng/mL for LUM/DBL. The lower limit of quantification was 10 ng/mL ART/ DHA and 5 ng/mL for LUM/ DBL. The mean intra-run precision were < 4.7% and the inter-run precision were < 4.4% for all the analytes. The mean percentage recovery values were >93.2%. No matrix effect was detected for all the analytes and the IS.

The validated method was successfully applied to determine the plasma concentrations of ART, DHA, LUM and DBL in pregnant and non-pregnant women volunteers in a multiple-dose pharmacokinetics study over the course of 336 hours.

MODELING HOST-PARASITE INTERACTIONS IN MALARIA BLOOD-STAGE INFECTIONS IN RHESUS MACAQUES

Luis L. Fonseca[1], Chester J. Joyner[2], Celia Saney[2], Alberto Moreno[2], John W. Barnwell[3], Mary R. Galinski[2], Eberhard O. Voit[1]

[1]Georgia Institute of Technology, Atlanta, GA, United States, [2]Emory University, Atlanta, GA, United States, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States

Malaria is globally the most deadly parasitic disease in humans, and the long-time coexistence with malaria has left indelible marks in the human genome that are the causes of a variety of genetic disorders. Anemia is the most common and severe complication of malaria, yet the root causes and mechanisms involved in malarial anemia are unclear and very difficult to study in humans. Non-human primate model systems enable the study and quantification of underlying, causative factors of malarial anemia, and particularly the onset of severe anemia. A discrete recursive model was developed to simulate host-parasite interactions during the blood stage infection; it accounts for reticulocytes, red blood cells (RBCs), and infected RBCs. The parameters of this mechanistic model were optimized against the readouts of individual macaque data, which had been obtained in the course of *Plasmodium coatneyi* and *P. cynomolgi* infections of cohorts of malaria-naïve rhesus macaques (*Macaca mulatta*). The model allowed detailed estimations of the levels of erythropoietic output, reticulocyte lifespan, RBC removal, and the immune response against the parasite in each macaque. The results showed that rhesus macaques have a response to a *P. cynomolgi* infection that is difficult to understand: As expected, the infection resulted in anemia, yet 60% of the RBCs were lost by bystander effect a mechanism other than parasite invasion. To compensate for the severe anemia, the host released younger reticulocytes and increased the erythropoietic output. These responses, however, appeared to be poorly coordinated, as the release of younger reticulocytes occurred too early, while anemia had not yet set in, thereby probably aiding the parasite more than the host. Increased production of RBCs was only detected after treatment that lowered the parasitemia. The model also showed that, similarly to humans, reticulocytes in rhesus macaques circulate for about 24h before becoming mature RBCs. Anemia, as a sequela of malaria, was due in 60% to bystander destruction of RBCs, and by an inability of the host to up-regulate erythropoiesis before suppression of parasitemia.

1074

GLOBAL ECONOMIC COSTS DUE TO *PLASMODIUM VIVAX* MALARIA TREATMENT AND THE COST-BENEFIT OF RADICAL CURE

Angela Devine[1], Katherine E. Battle[2], Rosalind E. Howes[2], Ric N. Price[3], Yoel Lubell[1]

[1]Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand, [2]Big Data Institute, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom, [3]Menzies School of Health Research, Darwin, Australia

The global cost burden related to the treatment of vivax malaria has not been assessed. Here we estimated the current global economic cost of illness to healthcare providers and patient households and to explore the potential cost-benefit of implementing radical cure following a normal G6PD test result. Estimates of the cost of vivax malaria treatment for healthcare providers and patient households were collated from a literature review and primary costing studies, and combined with case estimates generated by the Malaria Atlas Project. A cost-benefit analysis of implementing effective global radical cure compared the cost of G6PD screening and supervised radical cure with the cost savings from the prevention of relapses. It was assumed that when adhered to, the 14-day primaquine regimen was 85% effective and required 3.5 healthcare worker days to supervise daily therapy (valued at one gross domestic product per capita per day). The estimate of the global cost of *P. vivax* was US$330 million (range US$205-459 million). Adopting a policy of screening for G6PD deficiency and delivery of highly effective radical cure was projected to save US$45 million per year from the societal perspective. Household costs decreased by US$124 million; however, provider costs increased by US$80 million attributable primarily to the inclusion of supervised primaquine therapy. The global societal costs of vivax malaria are substantial, but can be reduced through the use of effective radical cure following screening for G6PD deficiency. Novel, less costly interventions for ensuring adherence to primaquine regimens for effective radical cure are needed to reduce healthcare provider costs and provide a pathway to malaria elimination.

MULTIPLICITY OF INFECTION - HOW TO ESTIMATE IT AND HOW TO DESIGN YOUR STUDY

Kristan A. Schneider

University of Applied Sciences Mittweida, Mittweida, Germany

Multiplicity of infection (MOI), i.e., the number of super-infections, is a potent measure of transmission intensities in malaria, which can be incorporated into metrics for monitoring disease-control interventions. It can be readily estimated from molecular data gained from parasite-positive blood samples using different methods, some of which use ad hoc approximations while others are based on statistical models. While the focus has been on applications, the statistical properties of such methods and their impact on study designs have received less attention. Targeted to theoreticians and applied researchers, we present the statistical properties of a maximum-likelihood (ML) method to estimate MOI along with allele frequencies at molecular markers and compare them with some ad hoc methods. Particularly, we report on the asymptotic and finite-sample properties. While the ML estimate has the typical desirable asymptotic properties (asymptotic unbiasedness, consistency, efficiency) and adequate finite-sample properties, alternative ad-hoc methods might be severely biased. Particularly, ad hoc methods are not asymptotically unbiased, leading to misinferences even in large samples. Additionally, the ML estimate is relatively robust against model violations, as confirmed by a simulation study. Furthermore, the method is easy to compute and available as an R script. Moreover, it is possible to adapt the statistical model for study design purposes in order to ensure precision and accuracy goals when estimation MOI and allele frequencies. We apply illustrate the methods on a data set from Venezuela and exemplify sample-design issues.

CAUSAL DISCOVERY WITH KERNEL INDEPENDENCE TESTS FOR UNDERSTANDING AND MODELLING SEASONALITY OF MALARIA TRANSMISSION

Rohan Arambepola

University of Oxford, Enfield, United Kingdom

Seasonality in malaria transmission is observed widely around the world and varies greatly between areas, even varying from village to village in the same region and between different years. Many environmental factors have been identified as possible drivers of seasonality, including temperature, rainfall and vegetation. Many studies have also considered these covariates with various time-lags. Other data summaries may also be considered, such as mean monthly rainfall or total rainfall over a set time interval, as well as non-environmental factors, resulting in a large number of candidate drivers of seasonality. Due to the many possible covariates and highly variable nature of malaria seasonality around the world, standard regularisation techniques in machine learning may have trouble correctly identifying important covariates. We performed causal inference

to identify the most significant covariates for the temporal prediction of malaria transmission. Recent developments of kernel-based independence tests have led to a number of potential non-parametric independence and conditional independence tests which allow us to identify non-linear causal relationships. We used the Hilbert Schmidt Independence Criterion as our independence test and applied the pc-algorithm for causal discovery to a dataset of temporal and spatially-indexed malaria case data from health facilities in Mozambique along with satellite-based covariate data, including ecological covariates such as vegetation indices, land surface temperature and rainfall, all at multiple time-lags. We used the resulting causal relationships to cluster related covariates and identify significant covariates for modelling seasonality of malaria transmission.

1077

IMPACT OF GPS DISPLACEMENT AND SAMPLE SIZE ON LOCAL RISK MAPS OF MALARIA

Punam Amratia[1], Paul Psychas[1], Benjamin Abuaku[2], Colins Ahorli[2], Justin Millar[1], Samuel Oppong[3], Denis Valle[1]

[1]University of Florida, Gainesville, FL, United States, [2]Noguchi Memorial Institute for Medical Research, University of Ghana, Accra, Ghana, [3]National Malaria Control Programme, Accra, Ghana

Maps of disease risk have proven to be useful tools for strategic planning of malaria prevention and control activities at the national level and often are built using data from demographic health surveys (DHS) with GPS information. For local-mapping efforts though, demographic health data lacks the fine-grain resolution required to infer spatial heterogeneity and suffers from GPS displacement to protect the confidentiality of survey respondents. However, conducting prevalence-based surveillance is frequently expensive and infeasible to sustain especially if extensively done. But, if sampling efforts were minimized to the least amount required to power mapping efforts it could be sustained for longer periods. The aim of this work is to 1) determine the impact GPS displacement has for local mapping efforts that rely on precise spatial covariates for accurate model predictions and 2) illustrate the minimum sample size required to make local-level fine-scale maps without compromising the underlying spatial trends. Using a geostatistical model in a Bayesian framework, we demonstrate modelling techniques for micro-scale spatial heterogeneity of malaria in northern Ghana between 2010 and 2013 and then displace the known coordinate locations up to five kilometers to match standard displacement practices. We also randomly sampled between 10 - 90 % of the original survey at increments of 10% to determine how the model would predict at lower sample sizes. The maps created show a unique north-east to south-west trend in malaria prevalence. Interestingly, differences greater than 10% in predicted prevalence estimates were observed with and without GPS displacement, which might have important implications for local operational malaria prevention and control activities. Maps using At least 30% of the original sample size were able to demonstrate a similar spatial trend, without compromising the uncertainty in the model predictions. The high variability in malaria prevalence over a small region coupled with the strong impact of GPS displacement indicate important short-comings of country level spatial modelling for programmatic purposes.

SUPPORTING DECISION-MAKING FOR MALARIA ELIMINATION IN SOUTH AFRICA: A MATHEMATICAL MODELLING APPROACH

Sheetal Prakash Silal[1], Lisa J. White[2], Aparna Kollipara[3], Mandisi Moya[1], Rebecca Graffy[4], Eric Mabunda[5], G. Malatje[6], Bheki Qwabe[7], Yogan Pillay[8], Devanand Moonasar[8]

[1]Modelling and Simulation Hub, Africa, University of Cape Town, Cape Town, South Africa, [2]Oxford University, Oxford, United Kingdom, [3]Malaria Elimination Initiative, University of California San Francisco, San Francisco, CA, United States, [4]Clinton Health Access Initiative, Boston, MA, United States, [5]Limpopo Provincial Department of Health, Limpopo, South Africa, [6]Mpumalanga Provincial Department of Health, Mpumalanga, South Africa, [7]KwaZulu-Natal Provincial Department of Health, Durban, South Africa, [8]National Department of Health, Pretoria, South Africa

Having made substantial progress in controlling malaria and reducing deaths from the disease since 2000, South Africa is attempting to achieve malaria elimination by 2020. With heterogeneous incidence across provinces and a high proportion of imported cases, districts within provinces are faced with their own unique challenges and conditions, and solutions need to be adapted as necessary. There is no "one size fits all" intervention for malaria elimination due to the range of available interventions acting at different stages of the parasite life cycle and the diverse transmission landscape. Mathematical models have in the past provided a valuable framework for analysing the dynamics of malaria transmission to predict the impact of interventions in the design of optimal strategies. An epidemiological-economic model was developed to predict the path to elimination by 2020 for the three endemic provinces in South Africa. The model included several features such as details on the environmental conditions and biology of malaria transmission, infection and disease in the geographical region under study. The biological mechanisms were layered over a population distribution and behaviour sub-model that would reflect the way individuals live and move as well as the key features of their treatment-seeking behaviour. Developed alongside available health system data, the model was calibrated to mimic trends and patterns observed in the data. Simulated interventions included scaling up of Indoor Residual Spraying, Active Case Detection, mobile clinics and mass screening activities. These interventions were costed to inform the development of an investment case to support malaria financing and budgeting and determine a cost-effective path to achieving malaria elimination by 2020.

1079

THE ROLE OF HUMAN AND VECTOR MIGRATION, SEASONAL HETEROGENEITY, AND OPTIMIZED TARGETING OF LIMITED ANTI-MALARIAL INTERVENTIONS IN ACHIEVING MALARIA ELIMINATION IN THE SAHEL

Prashanth Selvaraj, Jaline Gerardin

Institute for Disease Modeling, Bellevue, WA, United States

Although malaria transmission has decreased in many parts of the world, the Sahel in Africa still faces high burden. In this highly endemic setting, malaria is very seasonal, resulting in extreme highs and lows of transmission through the year. This extreme seasonality may offer short but high impact windows of opportunity for the deployment of anti-malarial strategies. Using the entomological data collected during the Garki project of the 1970's, we develop a spatial mathematical model to explore how small pockets of perennial vector habitat can sustain transmission through low periods, how vector migration topologies affect the reseeding of transmission after the dry season and impact the success of localized vector control, and how optimally timed and targeted vector control strategies can effectively suppress transmission. This modeling framework is used to simulate the interventions deployed during the Garki Project and understand why and how malaria returned after the program was terminated, and further used as a test bed for predicting what interventions would be needed to efficiently reduce burden and eventually achieve elimination in Sahelian settings.

1080

THE IMPACT OF SEASONAL VARIATION IN THE DETECTION OF CLINICALLY RELEVANT *PLASMODIUM FALCIPARUM HRP2* GENE DELETIONS: A MODELLING STUDY

Oliver J. Watson[1], Robert Verity[1], Azra C. Ghani[1], Antoinette K. Tshefu[2], Melchior K. Mwandagalirwa[2], Steven R. Meshnick[3], Jonathan B. Parr[3], Hannah C. Slater[1]

[1]MRC Centre for Global Infectious Disease Analysis, Imperial College London, London, United Kingdom, [2]University of Kinshasa, School of Public Health, Kinshasa, Democratic Republic of the Congo, [3]Division of Infectious Diseases, University of North Carolina, Chapel Hill, NC, United States

The introduction of rapid diagnostic tests (RDTs) has enhanced the diagnosis of malaria, with the most widely used RDTs detecting *P. falciparum* histidine-rich protein 2 (PfHRP2). However, false-negative RDTs due to *pfhrp2/3* gene deletions have now been reported in multiple locations across Africa. In February 2018, the WHO issued guidance advising national malaria control programme (NMCP) managers to investigate suspected false-negative RDT results. This included a protocol for estimating the prevalence of *pfhrp2/3* deletions by sampling from symptomatic *P. falciparum* patients seeking treatment at public health facilities, with sampling to be completed within an 8-week interval. The specific interval chosen, however, could lead to bias in the observed prevalence of *pfhrp2/3* deletions. Here we present an extension to a published individual-based model of malaria transmission to characterise the impact of seasonality on *pfhrp2/3* deletions. Our modelling predicts that the observed prevalence of *pfhrp2/3* deletions is higher when monoclonal infections are more prevalent, with the highest prevalence observed when sampling from younger children at the start of the rainy season. As the rainy season progresses, individuals are more likely to be superinfected and acquire wild type parasites, resulting in positive RDT results and a decrease in observed *pfhrp2/3* deletions. Our predictions are consistent with data from the Democratic Republic of Congo where children were more likely to be monoclonally infected with *pfhrp2* deleted parasites if the samples were collected during periods of lower relative transmission intensity (MW p-value = $1.92e^{-7}$) and if the individuals were younger (MW p-value = $9.47e^{-4}$). Decisions made concerning whether to switch from HRP2-based RDTs should thus be made in the context of both the age of patients and time in the transmission season that they were sampled. We have mapped which regions in Africa have the greatest potential for bias in the observed prevalence of *pfhrp2/3* deletions, and identify the least biased sampling intervals for each level 1 administrative region to help guide NMCP surveillance strategies.

1081

MODELLING THE POTENTIAL IMPACT ON SPREAD OF ARTEMISININ AND PARTNER-DRUG RESISTANCE OF INTERMITTENT PREVENTIVE THERAPY OF MALARIA IN PREGNANCY

Deus Thindwa[1], Patrick G.T. Walker[1], Anja D.J. Terlouw[2], Lucy C. Okell[1]

[1]MRC Centre for Outbreak Analysis and Modelling, Department of Infectious Disease Epidemiology, Imperial College London, London, United Kingdom, [2]Department of Clinical Sciences, Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Intermittent preventive treatment of malaria in pregnancy (IPTp) in high or moderate malaria-endemic settings significantly reduces maternal malaria episodes, maternal and foetal anaemia, placental parasitaemia, low birth weight and neonatal mortality. Development of sulfadoxine pyrimethamine resistance has reduced the efficacy of IPTp in some areas of Africa, prompting the World Health Organisation to consider switching to dihydroartemisinin-piperaquine (DHA-PQP). We explore if widespread use of IPTp-DHA-PQP could accelerate the spread of artemisinin and piperaquine resistance and reduce DHA-PQP benefit to the wider population. We developed a 4-strain malaria transmission model, which includes mosquito dynamics, heterogeneous biting preference, immunity, case management of clinical infections, parasite survival rates using data from Cambodia, recombination, pregnancy rates, infectiousness in pregnancy, and IPTp frequency. Percentage resistance, computed as prevalence of low or high resistant parasites in a population of all parasites including wild-types, is used to explore the chance and rapidity of resistance spreading. We show that IPTp-DHA-PQP can promote the spread of resistance but its effect is much smaller compared to effect of case management in the general population. Moreover, if fitness cost of resistance is assumed via increased resistance parasite clearance rate, resistance cannot spread under certain IPTp frequency and coverage. We also show that resistance will spread faster with higher pregnancy rates, higher infectiousness of pregnant women, and more frequent IPTp. We have demonstrated that IPTp can promote the spread of DHA-PQP resistance only if the proportion of women in IPTp exceeds a threshold where resistant parasites have a sufficient advantage over sensitive parasites.

1082

MODELLING COUNTRY-LEVEL MALARIA PREVALENCE USING DHS DATA: COMPARISON OF MODEL APPROACHES

Kok Ben Toh, Denis Valle

University of Florida, Gainesville, FL, United States

Geospatial statistical models are now widely used in malaria epidemiology to identify risk factors, assessing efficacy of intervention program, and to produce reliable and comprehensive malaria risk maps. Many modelling approaches have been used in the literatures, e.g. Gaussian point process model, commonly implemented using Bayesian MCMC method (also known as Bayesian geospatial model, BGM) or stochastic partial differential equation (SPDE) approximation method, generalized linear model (GLM) and P-splines regression. The abundance of methods calls for comparison study as it can inform the researchers on selecting the right model. However, such studies are limited and their findings may not be applicable as the geographical scope changes. In this study, we compared the predictive performance of various techniques in modelling malaria prevalence in six African countries (Burkina Faso, D.R. Congo, Ghana, Nigeria, Togo and Uganda) separately, using their latest DHS data. These techniques are BGM, SPDE, stepwise GLM, elastic net regression, generalized additive model (GAM), random forest and gradient boosting regression tree. We found that the Gaussian process methods, BGM and SPDE, are generally reliable for country-level malaria modelling. However, GAM approach can be on par or even outperform the Gaussian process methods in some countries. Tree-based models, which are increasingly prominent methods in ecology and epidemiology models, perform poorly in this exercise. Given that fitting GAM takes only a small fraction of time required to run BGM or even SPDE approximation, we think that GAM is a good alternative and should be considered in malaria models.

1083

SUBSTANTIAL REDUCTION IN THE TRANSMISSION OF *PLASMODIUM FALCIPARUM* LOW-DENSITY INFECTIONS ASSOCIATES WITH TRANSMISSION-BLOCKING VACCINES *IN SILICO*

Andre Lin Ouedraogo, Edward A Wenger

Institute for Disease Modeling, Bellevue, WA, United States

The continued transmission of low-density *Plasmodium falciparum* infections from humans to mosquitoes may pose challenges for malaria control and elimination efforts as they cause insufficient symptoms to trigger anti-malarial treatment for parasite clearance. While high-density infections are observed to induce transmission-blocking antibodies, low-density infections may not. A recent field study indicated that low-density infections can remain infectious over an extended period, contributing

to onward transmission--likely because functional transmission-blocking antibodies are insufficient and short-lived. Malaria transmission-blocking vaccines (TBVs) against sexual-stage surface antigens of *P. falciparum* are potentially effective tools for the reduction of malaria transmission from asymptomatically infected individuals who do not seek anti-malarial treatment. Here, we estimate the impact of the next generation of TBVs on malaria transmission and their relevance for elimination and eradication. Novel understandings of immune dynamics and antibody functionality against high- and low-gametocyte infections were used to design relevant properties of future TBVs, including potency and immunogenicity. The temporal and spatial impact of potential TBVs on malaria transmission is simulated across different transmission settings using an agent-based mechanistic model of within-host effects coupled to a vector model.

1084

INVECTS (INDOOR VECTOR CONTROL TESTING SIMULATOR): A 3D COMPUTER SIMULATION MODEL OF INDOOR MOSQUITO BEHAVIOR FOR RAPID EVALUATION OF VECTOR CONTROL TOOLS

Jeff Jones[1], Gregory P. Murray[1], Natalie Lissenden[1], Kobié Hyacinthe Toé[2], Vitaly Voloshin[3], Josephine E. Parker[1], Catherine E. Towers[3], Hilary Ranson[1], Sagnon N'Fale[2], David Towers[3], Philip J. McCall[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]Centre National de Recherche et de Formation sur le Paludisme (CNRFP), Ouagadougou, Burkina Faso, [3]School of Engineering, University of Warwick, Coventry, United Kingdom

Increasing insecticide resistance threatens recent advances in control of malaria in Africa; emerging arboviruses are linked with urbanization, human and vector behavior change; sustainable integrated control of multiple diseases will require more cost-effective approaches. Vector control remains under constant pressure to innovate, iterate and improve. Yet developmental pipelines for new tools are high risk, expensive and time-consuming processes, often hampered by results of tests that are poorly linked to the actual behavior of products in field settings. Improving the speed of this decision-making process is essential if the generation of novel, safe and appropriate tools is to be sustained. Indoor environments (the human home) harbor infection risks from endophilic and endophagic malaria vectors but have also provided the best methods to date. Additional opportunities almost certainly exist within the home. Using a unique room-scale video-tracking system, we have gained exceptional insight into the host-seeking behavior of *Anopheles gambiae* at human-occupied LLINs. We have utilized this information to create a novel virtual testing simulation of mosquito-host interactions within the indoor environment. This system enables rapid assessment of a wide range of innovative vector control ideas, both actual and theoretical, at marginal cost. The InVeCTS model is a software package, simulating vector behavior in a virtual mosquito population during interaction with human hosts and responses to specific vector control tools in a complex indoor spatio-temporal environment. The model operates at a level of granularity that reflects the complex nature of mosquito-host interactions not captured by coarser scale models. Our results show the model can explore mechanisms underlying the observed response of a mosquito population to insecticides on bed nets and the relative performances and benefits of particular bed net barrier designs. InVeCTS is an effective tool in response to the immediate challenge from the growth of resistance. Future model development will include increased spatial scales and multiple-host interactions.

1085

IDENTIFYING KEY FACTORS OF THE TRANSMISSION DYNAMICS OF DRUG-RESISTANT MALARIA

Tamsin E. Lee, Melissa Penny

Swiss Tropical and Public Health Institute, Basel, Switzerland

Development of resistance to malaria treatments remains a great threat to malaria control and continued transmission reduction. Understanding the key factors that increase the spread of drug resistance or emergence can guide intervention strategies. In particular, to inform risk versus benefits assessments in regards to mass treatment strategies and their potential impact on resistance in different settings. Mathematical modelling provides a framework to understand factors which contribute to the spread of malaria, and importantly can simulate specific drugs and different treatment strategies. The simplicity and relevance of the Ross-MacDonald has ensured that it continues to be a strong basis for a broader theory of mosquito-borne disease transmission and control. We present a model that builds upon these well-established foundations to understand drivers of resistance. Our model includes three infection classes: sensitive, partial-resistance and fully-resistant. These classes are flexible and could represent a single infection with an intermediary step to full-resistance, or each infected host carries two infections where one may be sensitive and the other resistant. Via sensitivity analysis of the model we find that the most effective way to control the spread of resistant infections is by interrupting the rate that more resistant infections replace less resistant infections, and as such this mechanism should be the focus of further research. Importantly, our results imply that reducing treatment has a comparatively small impact, since the most effective way to prevent resistance spreading throughout a population is by controlling the within-host mechanisms of resistance via pharamacokinetics. Our model serves as an introductory model that can act as the foundation for further studies of resistance drivers in a population, and compliment and inform within-host models of resistance.

1086

ASSESSING THE IMPACT OF IMPERFECT ADHERENCE TO ARTEMETHER-LUMEFANTRINE ON ONWARD TRANSMISSION OF THE *PLASMODIUM FALCIPARUM* PARASITE USING WITHIN-HOST MODELLING

Joseph D. Challenger, Azra C. Ghani, Lucy C. Okell

Imperial College London, London, United Kingdom

Artemether-lumefantrine (AL) is the most widely recommended and prescribed antimalarial worldwide. Clinical trials have clearly demonstrated its safety and efficacy. Timely access to quality-assured antimalarials is vitally important, both to ensure good clinical outcomes and minimise onwards transmission of the parasite. In recently published work, we developed a within-host model of falciparum malaria to assess the performance of AL in routine healthcare settings, where adherence to treatment may be imperfect. To do this, we utilised individual-level data on patient adherence. Here we focused on the parasitological outcomes for the patient: we now develop our investigation to quantify the impact that poor adherence has on malaria transmission. With the aid of malaria therapy data, we extend our model to include gametocyte production, explicitly modelling both the immature (sequestered) and mature parasites. With the aid of likelihood-free inference methods, we used individual-level data from clinical trials to calibrate a pharmacodynamic model, quantifying the drug action against sexual-stage parasites. Using our model, we highlight the importance of timely access to treatment by showing how delay to treatment leads to an increase in circulating gametocytes post treatment. In addition, we use adherence data for 482 patients taking a course of AL, collected in Tanzania in 2012, to assess the contribution that sub-optimal adherence makes to transmission of the malaria parasite.

1087

IN VITRO CULTURE OF A MADAGASCAR *PLASMODIUM VIVAX* ISOLATE IN HUMAN WHOLE BONE MARROW

Rajeev K. Mehlotra[1], Quentin Watson[1], Jurgen Bosch[1], Rosalind E. Howes[1], Tovonahary A. Rakotomanga[2], Arsène C. Ratsimbasoa[2], Peter A. Zimmerman[1]

[1]Case Western Reserve University, Cleveland, OH, United States, [2]National Malaria Control Programme, Ministry of Health, Antananarivo, Madagascar

Long-term cultivation of *Plasmodium vivax* (Pv) is challenging. Recently, we achieved success in maintaining Madagascar Pv isolates in *Saimiri boliviensis* (Sb) leukocyte-depleted whole blood for 36-233 days at parasitemia 0.1-0.4%. Reports of the occurrence of Pv in bone marrow (BM) have appeared from time to time in the literature. It is suggested that as with *P. falciparum*, the BM could be a niche for gametocyte production and maturation and/or a reservoir in Pv infections. Here, we attempted to culture a Madagascar Pv isolate in human leukocyte-depleted whole BM. A culture of cryopreserved patient isolate Ext3020 was initiated in complete AIM V medium containing 4% Sb blood. On day 30 post-culture, this culture was divided into 4 1-ml cultures: one culture each in Sb blood and 4% fresh BM (BM1, North American donor, Duffy genotype FyA+/B+) was maintained in AIM V medium under 10% CO_2 environment, whereas the other same set of two cultures was maintained in IMDM medium under 5% CO_2 environment. After 7 days, the cultures in Sb blood were further split to initiate new cultures in another fresh BM (BM2, North American donor, Duffy genotype FyA+/B–). These cultures were fed with Sb blood (obtained every 2 weeks) or BM1 or BM2 (both original), stored at 4° C, every 96-120 h, and their medium was changed daily. Imaging flow cytometry using Hoechst or a polyclonal *Plasmodium* MTIP antibody was used to assess parasitemia based on >200,000 cells. Standard Giemsa-stained slides confirmed culture of Pv, showing rings, late trophozoites/early schizonts, and possible gametocytes, with parasitemia 0.1-0.2%. The Pv isolate culture in BM1 maintained in IMDM medium under 5% CO_2 environment was ended on day 48 because of bacterial contamination, whereas all other cultures are being continuously maintained (BM1 [53+ days] and BM2 [46+ days] in AIM V 10% CO_2; BM2 [46+ days] in IMDM 5% CO_2). These results suggest that long-term culture of Pv isolates is possible in human whole BM.

1088

ASSESSING ORGANIZATIONAL CAPACITY TO DELIVER QUALITY MALARIA SERVICES IN RURAL LIBERIA

Swaliho F. Kamara[1], Wede Tate[1], Allyson R. Nelson[1], Lauretta N. Se[1], Lolade Oseni[2], Gladys Tetteh[2]

[1]Jhpiego, Monrovia, Liberia, [2]Jhpiego, Baltimore, MD, United States

Malaria prevalence in Liberia in children under five years is 45% nationally, and higher in rural counties. Since 2015, Maternal and Child Survival Program (MCSP) has worked with the Liberia Ministry of Health to rebuild and strengthen the health system. Organizational capacity of local public health agencies has been linked to service delivery performance. As part of an expansion of program support to additional high burden and neglected counties, MCSP assessed county health teams' (CHTs) organizational capacity to identify ways to improve quality of malaria health services. MCSP assessed five rural (of 15 total) CHTs' capacity using a modified organizational capacity assessment (OCA) tool. Areas examined were delivery of essential health services (service delivery), health information system (HIS), health workforce (HWF), and leadership/governance with a focus on malaria. A participatory approach was used allowing CHTs to self-evaluate with guidance from the assessment team. Probing techniques and item verification were used to assure validity of responses. The average score of the five CHTs was 83% (range: 67-100%) in service delivery, 65% for HIS (range: 50-100%), 78% for HWF (range: 50-100%), and 70% for leadership/governance (range: 50-100%). Findings show a range of reasonable organizational capacities to manage, monitor, and implement malaria services. Results will be used by MCSP to further strengthen and optimize CHTs' capacities to provide quality malaria services, with the goal of improving malaria prevention in pregnancy and case management at facility and community levels in five high-burden counties in Liberia. While there is reasonable capacity for malaria management in the counties assessed, MCSP will further optimize this capacity to ensure every malaria case receives quality care. This OCA methodology is applicable to other programs aiming to improve the quality of malaria service delivery.

1089

SAFETY AND FEASIBILITY OF APHERESIS TO HARVEST AND CONCENTRATE PARASITES IN SUBJECTS WITH INDUCED BLOOD STAGE *PLASMODIUM VIVAX* INFECTION

Anand Odedra[1], Rebecca Pawliw[1], Rebecca Watts[1], Kari Mudie[2], Glen Kennedy[2], David Lalloo[3], James McCarthy[1]

[1]QIMR Berghofer, Brisbane, Australia, [2]Royal Brisbane and Women's Hospital, Brisbane, Australia, [3]Liverpool School Tropical Medicine, Liverpool, United Kingdom

In the absence of a method to culture *Plasmodium vivax (P. vivax),* the only way to source parasites is *ex vivo*. This hampers many aspects of research on *P. vivax*, including evaluation of candidate hypnozoiticidal drugs. Currently, sporozoites can only be sourced using expensive, logistically complex and unreliable processes requiring transportation of *P. vivax* infected mosquitoes from endemic areas. Apheresis is the removal of a specific component of blood with the remainder being returned to the individual. We aim to assess a) safety of apheresis following inoculation of healthy subjects with *P. vivax, and b)* feasibility of apheresis to extract and concentrate all stages of *P. vivax*. One non-immune healthy human subject was inoculated with blood stage HMPBS13 *P. vivax* parasites and subjected to apheresis 10 days later. Blood samples from haematocrit (HCT) levels; 1%, 2%, 3%, 5% and 7% were tested by qPCR for the presence and concentration of asexual and sexual stages of *P. vivax*. Standard safety assessments were performed. Mosquito membrane feeding assays used percoll enriched blood taken pre-apheresis and apheresis samples taken from 1%, 2% and 3% HCT layers. Parasitemia was quantified by a validated qPCR method targeting the 18S rRNA gene of *P. vivax*, and gametocytes by qRT PCR targeting *pvs25* mRNA, a female gametocyte transcript. There were no serious adverse events and no significant safety concerns. Asexual and sexual parasites were successfully harvested using apheresis with highest concentrations in the 7% HCT and 5% HCT layers. Apheresis demonstrated a 335 fold increase in concentration of parasite genomes, and 3.7 fold increase in the *pvs25* mRNA transcript compared to a whole blood sample taken pre-apheresis. Downstream experiments including membrane feeding assays were inhibited by clotting of post-apheresis samples. Apheresis was safely carried out in a human volunteer experimentally infected with *P. vivax*, and can be used to extract asexual and sexual *P. vivax* parasites. Studies are underway to prevent apheresis sample clotting and improve laboratory processing in order to enhance parasite yields and downstream mosquito feeds.

1090

INTERMITTENT PREVENTIVE TREATMENT WITH DIHYDROARTEMISININ PIPERAQUINE IN YOUNG UGANDAN CHILDREN IN THE SETTING OF INDOOR RESIDUAL SPRAYING OF INSECTICIDE

Mary Kakuru Muhindo[1], Abel Kakuru[1], Patricia Awori[1], Paul Natureeba[1], Bishop Opira[2], Micheal Amailuk[1], Peter Olwoch[1], Noeline Nalugo[1], Jaffer Okiring[1], Leonard Opio[1], Theodore Ruel[3], Clark Tamara[3], Edwin Charlebois[3], Diane Havlir[3], Jagannathan Prasanna[4], Dorsey Grant[3], Moses R. Kamya[5]

[1]Infectious Diseases Research Collaboration, Tororo, Uganda, [2]Infectious Diseases Research Collaboration, Kampala, Uganda, [3]University of California San Francisco, San Francisco, CA, United States, [4]Stanford

University, Stanford, CA, United States, [5]Makerere University College of Health Sciences, Kampala, Uganda

Intermittent preventive treatment of malaria in infants (IPTi) is a promising strategy for the prevention of malaria in young children living in Africa. Dihydroartemisinin-piperaquine (DP) is safe and highly efficacious when used for the treatment of malaria and an excellent candidate for IPTi because of its prolonged post-treatment prophylaxis. However, the optimal dosing strategy for DP as IPTi is unclear. We conducted a double-blinded randomized controlled trial of two different IPTi with DP dosing strategies in a historically high transmission area of Uganda where the burden of malaria has been dramatically reduced following the implementation of indoor residual spraying of insecticide (IRS). A birth cohort of 183 children were randomized in a 1:1 ratio to receive IPTi with DP every 4 weeks or every 12 weeks from 8 weeks to 2 years of age followed by 1 additional year of follow-up after stopping IPTi. The incidence of malaria was measured using passive surveillance and the prevalence of microscopic or sub-microscopic parasitemia measured routinely every 4 weeks. Between 8 weeks and 2 years of age, children receiving DP every 4 weeks had a significantly lower incidence of malaria (0.02 vs 0.39 episodes PPY, p<0.001) and parasite prevalence (0.6% vs 3.8%, p<0.001) compared to children receiving DP every 12 weeks. Follow-up after stopping IPTi will be completed in May 2018, but preliminary results show that children who previously received DP every 4 weeks had a lower incidence of malaria compared to children who previously received DP every 12 weeks (0.79 vs 1.15 episodes PPY, p=0.04). Both treatment arms were safe and well tolerated. In summary, IPT with DP given every 4 weeks was superior to DP given every 12 weeks for the prevention of malaria during infancy and preliminary results indicate that this protection was extended for up to one year after stopping IPT. Indeed, the combination of IRS and IPTi with DP every 4 weeks virtually eliminated malaria during infancy in an area where children suffered ~ 5 episodes of malaria per year prior to the implementation of IRS in the absence of IPTi.

1091

COMPARISON OF TWO QUANTITATIVE ASSAYS TO MEASURE G6PD ACTIVITY IN A MALARIA RISK POPULATION IN WESTERN CAMBODIA

Worachet Kuntawunginn[1], Montri Arsanok[1], Soklyda Chann[2], Saowaluk Wongarunkochakorn[1], Huot Lychhea[2], Chaiyawat Mathavarat[1], Nuom Sarath[2], Chadin Thongpiam[1], Mok My[2], Kittijarankon Phontham[1], Va Soch[2], Kingkan Pidtana[1], You Yom[2], Parat Boonyarangka[1], Mitra Feldman[1], Sabaithip Sriwichai[1], Darapiseth Sea[2], Bertha Nyagaya- Wojnarski[3], Michele Spring[1], Krisada Jongsakul[1], Mariusz Wojnarski[1], Mark Fukuda[1], Chanthap Lon[1], Philip L. Smith[1]

[1]US Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [2]US Armed Forces Research Institute of Medical Sciences, Phnom Penh, Cambodia, [3]The George Washington University, School of Nursing, Northwest, WA, United States

Primaquine (PQ) is the only drug currently available for the radical cure and relapse prevention of *P. vivax*, but its widespread use is hampered by the risk of hemolysis in G6PD deficiency (G6PDd). Therefore accurate diagnosis of G6PD status is required for safe use of PQ and other 8-aminoquinolines such as tafenoquine. Pointe Scientific (PS) (Canton, Michigan) is currently one of the quantitative tests available on the market after discontinuation of the Trinity Biotech (TB) (Bray, Ireland) product. We assessed the performance of the PS and TB kits in a Cambodian malaria risk population. After calculating separate population medians using both kits from 414 healthy males, an adjusted median was then calculated, excluding values ≤ 10% of median. Patient values were categorized as either <60% or <30% of the adjusted median; those falling below 30% of the adjusted median were categorized as deficient. Simple linear regression analysis of our volunteer population yielded a slope of 0.93, an intercept of 0.64 and Pearson correlation coefficient is 0.946. The range of quantitation was 0.06 to 20.99 U/g Hgb for TB and 0.23 to 22.05 U/g Hgb for PS, yielding adjusted medians of 7.84 U/g Hgb (IQR 5.11-10.57) for TB and 8.11 U/g Hgb (5.67-10.55) for PS. 78/414 (18.8%) and 79/414 (19.1%) fell below the 60% G6PDd thresholds of 4.70 U/g Hgb and 4.87 U/g Hgb for TB and PS, respectively. Both kits classified 77/414 (18.6%) subjects as deficient using 30% G6PDd diagnostic thresholds of 2.35 U/g Hgb (TB) and 2.43 U/g Hgb (PS). These data show that the two kits yield comparable results and can be used interchangeably in our study population.

1092

CONTRIBUTION OF THE IMPROVING MALARIA CARE (IMC) PROJECT IN TRANSFORMING THE FACE OF MALARIA CONTROL FOR VULNERABLE POPULATIONS IN BURKINA FASO

Mathurin Dodo[1], Lolade Oseni[2], Danielle Burke[2], Linda Fogarty[2], Ousmane Badolo[1], Stanislas Nebie[1], Moumouni Bonkoungou[1], Thierry Ouedraogo[1], Youssouf Zongo[1], Maria Gouem[1], Youssouf Sawadogo[1], Bethany Arnold[2]

[1]Jhpiego, Ouagadougou, Burkina Faso, [2]Jhpiego, Baltimore, MD, United States

In Burkina Faso, malaria seriously affects vulnerable populations (children under 5 and pregnant women). The 6-year (2013-2019) Improving Malaria Care Project (IMC) funded by PMI aims to improve the quality of malaria prevention, diagnosis and treatment to reduce malaria morbidity and mortality by 50% from baseline figures. IMC has also focused on clinical and health information capacity-building and national-level system change. From 2014-2016, 1,819 providers from 1,349 health facilities in 53 (76%) districts and 185 trainers were trained on new malaria treatment guidelines developed in partnership with the NMCP. 1,300 health workers were trained to use monthly report forms, and providers received post-training supervision. 897 providers from referral hospitals were oriented on severe malaria case management. 38 managers were trained to roll out malaria quality improvement systems. IMC is also supporting the government to change national systems for malaria control, data collection, and supervision and improve data quality. From 2013 to 2016, the number of total malaria deaths decreased by 37% (6,294 to 3,974) and the overall fatality rate decreased by 40% (from 1.5% to 0.9%). Malaria deaths amongst pregnant women decreased by 75% (151 to 38) and the malaria fatality rate declined by 83% (0.6% to 0.1%). For children <5, malaria deaths decreased by 43% (4,761 to 2,730) and the fatality rate declined by 44% (2.7% to 1.5%). IMC-supported sites also distributed 6,347,503 courses of ACTs, 1,220,537 2nd doses of IPTp, and 1,146,185 LLINs between Jan. 2014 and Sep. 2017, possibly averting an estimated 32,435 deaths and 2,758,327 DALYs (calculated using the PSI Impact Calculator). To achieve this, IMC's work was associated with positive impacts. IMC will continue to pursue a comprehensive, multilevel approach, including capacity building, updating the malaria prevention and treatment guidelines according to WHO recommendations, aligning training packages, and improving the malaria data system, and work towards the goal of reducing malaria morbidity and mortality.

1093

MALARIA RESPONSE PLAN IN TIMES OF HIGH TRANSMISSION: AN APPROACH TO IMPROVING THE QUALITY OF HOSPITAL MALARIA MANAGEMENT

Ousmane Badolo[1], Stanislas Nebie[1], Youssouf Sawadogo[1], Thierry Ouedraogo[1], Moumouni Bonkoungou[1], Mathurin Dodo[1], Danielle Burke[2], William Brieger[3], Gladys Tetteh[2]

[1]Jhpiego, Ouagadougou, Burkina Faso, [2]Jhpiego, Baltimore, MD, United States, [3]Johns Hopkins University, Baltimore, MD, United States

Malaria is a major public health problem in Burkina Faso. According to the 2016 HMIS statistical yearbook, it is the main cause of consultation (45%), hospitalization (23%) and deaths (18%) in health facilities. During the rainy season (between June and September), there is an upsurge of

malaria cases exceeding the capacity of care in hospitals and causing a high number of deaths especially in children under five years. To help reduce the severity of malaria cases and malaria-related deaths in referral hospitals, the Improving Malaria Care Project (IMC) funded by PMI provided support to the National Malaria Control Program to develop and implement Malaria Preparedness and Response plans in 11 out of 16 regional Hospitals from March to October 2017. The main purpose of these plans was to provide guidance and coordinated action at hospital-level to prepare for and properly treat cases of severe malaria and reduce malaria-related deaths during the period of high transmission, which runs from July to October. Each hospital developed its plan according to a defined outline which included the following strategies: i) capacity building of providers on malaria treatment protocols; ii) the security of a stock of commodities including blood for transfusions in cases of anemia; iii) redeployment / reinforcement of staff in care units; iv) communication; and v) data collection. The implementation of these plans took place from July to October 2017. Follow up visits were organized from October 24 to November 8, 2017. Review of the hospital data revealed that despite the increase in number of severe malaria cases, from 6800 to 9100, malaria-related deaths decreased from 5% to 4.3% in the general population and from 6.2% to 5.4% among children under 5 in these hospitals between 2016 and 2017. Response plans may provide a way to reduce malaria mortality, which needs to be further studied, and which each hospital may want to consider incorporating into its annual work plan.

1094

WARD LEVEL APPROACH TO DATA VALIDATION: A PANACEA TO DATA QUALITY IMPROVEMENT IN KANO STATE, NIGERIA

Amina Abdullahi Umar[1], Usaini Bala[1], Olufemi Ajumobi[1], Adewole Adefisoye[1], Junaidu Yakubu[1], Hisham Imamu-Deen[1], Idris Abubakar[1], Saleh Muhammad[1], Bala Kastuda[1], Ndadilnasiya Waziri[1], Shelby Cash[2], Kwame Asamoa[2]

[1]African Field Epidemiology Network, Abuja, Nigeria, [2]US Centers for Disease Control and Prevention, Atlanta, GA, United States

Poor data quality is a major problem in Nigeria's routine health information system. Prior methods of data validation (DV) activities occurred monthly at local government area (LGA) level comprising LGA staff, Heads of health facilities (HoHF), record officers (ROs) and partners before entry of data into the District Health Information System-version 2 (DHIS-2) platform by the Monitoring and Evaluation (M&E) officer. This method is time consuming taking a whole day or more and the payment of per diem for participants. The cost involved was borne by a partner and therefore not sustainable. In June 2017, the US CDC-funded Malaria Frontline Project (MFP) implemented in 20 out of 44 LGAs in Kano State initiated ward-level data validation. A ward-level DV meeting was piloted in Dawakin-Tofa LGA for 3 months and scaled-up to all 20 LGAs. Averagely, an LGA is made of 8 to 13 wards with 3 to 5 health facilities (HF) in each ward. A ward technical officer at the apex HF in each ward convenes a monthly DV meeting of HoHF and ROs in the ward to validate data under the supervision of LGA level senior staff. The aggregated data is sent to LGA where M&E officer collates all ward validated data for entry into the DHIS-2 platform. Due to the closeness of facilities within a ward and less time spent on validation, no per diem is required. The ward level DV meeting has consistently improved data completeness from 97.5% in Q2 to 98.6% in Q4 of 2017 in the LGAs; timeliness has also increased by 7.2% from Q2 to Q4. Due to more HFs reporting, there is an increase in uptake of first dose of Intermittent preventive treatment of malaria in pregnancy indicator among antenatal care attendees from an average of 90% to 95% in DT, and from 77% in Q3 to 80% in Q4 2017 in other 19 LGAs. DVMs helped identify 27% gaps with bed nets requirement for children under five and pregnant women in DT in Q4. The ward-level DV is sustainable, non-monetary dependent and health care system-driven. It has built capacity of health care workers in ensuring quality data. We recommend state and nation wide up-scaling of this approach.

1095

CHANGES IN CONFIRMED AND CLINICAL MALARIA CASES REPORTED THROUGH THE DHIS 2 SOFTWARE PLATFORM IN KENYA, 2011-2015

Sophie W. Githinji[1], Robinson Oyando[2], Josephine Malinga[3], Waqo Ejersa[4], Abdinasir Amin[1], Yazoume Ye[1]

[1]ICF Macro Inc, Nairobi, Kenya, [2]KEMRI Wellcome Trust Research Program, Nairobi, Kenya, [3]Swiss Tropical and Public Health Institute, Basel, Switzerland, [4]National Malaria Control Program, Ministry of Health, Kenya, Nairobi, Kenya

Health facility-based data are valuable for monitoring trends in malaria morbidity and evaluating the impacts of malaria interventions. To examine the relationship between malaria testing and the quality of surveillance data, we conducted a 5-year retrospective, longitudinal analysis of reported outpatient malaria cases from Kenya's DHIS 2 software platform, stratified by age (<5 and ≥5 years), from January 2011 to December 2015. The change in number of confirmed and clinical malaria cases reported between 2011 and 2015 was determined. Testing rates were determined from 2013 onward, because data on testing were not available for the preceding years. Confirmed malaria cases reported in children <5 years increased by 79.2% (992,362 to 1,777,959) and clinical malaria cases decreased by 77.2% (3,083,595 to 702,248). Confirmed malaria cases reported in patients ≥5 years increased by 121.2% (1,680,574 to 3,717,092) while clinical malaria cases decreased by 70.1% (4,928,535 to 1,475,610). In 2013, only 0.1% (5,308 of 8,753,287) of reported cases (<5 and ≥5) were tested for malaria by microscopy or Rapid Diagnostic Tests (RDTs). In 2015, 61.2% (4,697,027/7,672,909) of reported cases (<5 and ≥5) were tested for malaria by microscopy or RDTs. Scale-up of RDTs since 2013 and continued emphasis on parasitological confirmation before treatment may be responsible for the observed increase in the number of reported cases tested. This implies improvements in case-detection practices, supported by the decrease in presumptive cases. Improvements in reporting of malaria cases through DHIS 2 and the revision of data capture tools to record numbers tested and malaria-positives detected may also have supported reporting of confirmed cases. These findings indicate that the quality of malaria surveillance in Kenya has improved. Efforts must continue, to sustain that achievement.

1096

COST-EFFECTIVENESS ANALYSIS OF MEDICINE QUALITY SCREENING DEVICES IN LAOS

Nantasit Luangasanatip[1], Celine Caillet[2], Serena Vickers[2], Stephen Zambrzycki[3], Paul N. Newton[2], Yoel Lubell[1]

[1]Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand, [2]Lao-Oxford Mahosot Tropical Medicine Research Unit, Mahosot Hospital, Vientiane, Lao People's Democratic Republic, [3]Georgia Institute of Technology, Georgia, GA, United States

Poor quality antimalarials are a common problem in many malaria-endemic areas, leading to devastating consequences including increased morbidity, mortality and economic losses. Field detection devices to screen the quality of medicines are increasingly available, however, their cost-effectiveness is not known. To evaluate the cost-effectiveness of handheld devices for medicine quality screening during drug inspections in pharmacies in Laos, conservatively focusing on their benefit in detecting substandard or falsified antimalarial artemisinin-based combination therapies (ACTs). We use a decision tree model to simulate the deployment of devices in inspections at the pharmacy level. Seven devices were evaluated including Minilab, Truscan, MicroPHAZIR, 4500a FTIR, NIRScan, Progeny and Paper Analytical Devices (PADs). We performed two scenario analyses of the prevalence of poor quality medicines. In Scenario 1, 20% of ACTs were assumed to be substandard and 20% falsified, while in Scenario 2, 10% were assumed to be substandard and 5% falsified. We evaluated different sampling strategies using 1, 2, or 3 sample(s) for each brand of ACT. Analyses were carried out for each device against a baseline of visual

inspections, and in a multiway head-to-head comparison of all devices and sampling strategies. In Scenario 1 all but one devices were cost-effective with a 1-sample strategy. In Scenario 2 only three devices, the Minilab, NIRScan, and PADs were cost-effective with a 1-sample strategy. In the multi-way comparative analysis of all devices, in both scenarios the Minilab with a 1-sample is the most cost-effective option, followed by the Minilab with a 2-sample strategy, and the NIRScan with a 2-sample strategy. Routine inspection for poor quality ACTs with field detection devices is cost-effective in Laos where malaria is endemic. This information can aid policy-makers or regulators considering investment in handheld screening devices to improve medicine quality and reduce the undesired health and economic burden associated with poor quality medicines.

1097

DEVELOPING A DATA STANDARD FOR MALARIA

Lesley J. Workman[1], Karen I. Barnes[1], Philippe J. Guerin[2], Elizabeth N. Allen[1]

[1]WorldWide Antimalarial Resistance Network (WWARN), Cape Town, South Africa, [2]WorldWide Antimalarial Resistance Network (WWARN), Oxford, United Kingdom

Until recently there was no international standard to guide data capture for antimalarial drug efficacy and safety, resulting in a large heterogeneity among studies. The WorldWide Antimalarial Resistance Network (WWARN) partnered with Clinical Data Interchange Standards Consortium (CDISC) and the Critical Path Institute (C-Path) to develop these standards for malaria building on WWARN's experience in establishing a global data platform for malaria studies. WWARN's proposal to CDISC to develop a data standard was accepted in December 2014. Key stakeholders from the malaria community were invited to join a working group, to share protocols, case record forms (CRFs), data dictionaries and to review draft standards. The scoping and planning of the project was followed by identifying key concepts which guided the development of the draft standard. These draft standards were sent to the wider malaria research community for open review, comments resolved then submitted to CDISC for internal review followed by public review and publication. The malaria data standard was published in 2016. This was followed by the development of a training course and assessment, currently under peer review. The standard applies primarily to uncomplicated malaria (P *falciparum* and P *vivax*), and consists of a Malaria Therapeutic Area User Guide (TAUG-Malaria), which includes concept maps, required metadata, Standard Data Tabulation Model (SDTM) examples, an analysis considerations section, controlled terminology and an updated WWARN Clinical Data Acquisition Standards Harmonization (CDASH)-compliant CRF. The development of a data standard for malaria has been an unprecedented collaborative effort to overcome large heterogeneity which have prevailed in antimalarial drug efficacy trial to date. The documents will guide prospective data collection, reduce heterogeneity, facilitate future re-use of data including individual patient meta-analyses. This achievement paves the way of providing data standards for other poverty related diseases as it has recently been done for Ebola in collaboration with the Infectious Diseases Data Observatory (IDDO).

1098

PREVALENCE OF HIV, HEPATITIS B AND HEPATITIS C INFECTION AMONG POTENTIAL PARTICIPANTS TO EXPERIMENTAL VACCINES TRIALS IN A RURAL AREA OF BURKINA FASO

Alphonse Ouedraogo[1], Moise Kaboré[1], Aissata Barry[1], Sam Coulibaly[1], Daouda Ouattara[1], Desire W. Kargougou[1], Noely Henry[1], Alfred B. Tiono[1], Amadou T. Konaté[1], Issa Nébié[1], Sodiomon B. Sirima[2]

[1]Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, [2]Centre National de Recherche et de Formation sur le Paludisme. Groupe de Recherche et Action en Santé, Ouagadougou, Burkina Faso

In Burkina Faso, there are few studies that reported the prevalence of HBV and HCV in the general population. During early clinical development phase of vaccines, volunteers with these conditions are often excluded from participating to the trials due to safety concerns and the need to minimize any interference with the outcomes measures. This study aimed to evaluate the prevalence of hepatitis B (HBV), hepatitis C (HCV) and the Human Immunodeficiency Virus (HIV) infections in potential trial participants in the context of vaccines study sites characterization. A voluntary testing was opened to anyone interested. These testing were held at the research clinics of Saponé and Banfora. Rapid diagnosis tests to detect the surface antigen HBs, the anti-HCV antibodies and HIV were carried out on apparently healthy persons who voluntarily answered a range of questions before the venous blood sample collection. A total of 450 individuals were screened of whom 247 (54.89%) were women and 203 (45.11%) were male. The age ranged from 15 to 70 years (with a mean of 30.54 ± 10.01 years). The prevalence of HBV, HCV and HIV was 6.20% (95% CI: 3.59-9.88%), 2.71% (95% CI 1.10-5.51), and 3.78% (95% CI 2.29-6.10), respectively. The most affected group were subjects aged 30-40 years for HCV (3.88%), and 20-40 years for HBV (13.28%) and HIV (8.44%). There was no gender difference for any of the infections tested. No case of co-infection was reported. Overall the prevalence of HBV and HCV were relatively low. However, the prevalence of HIV was higher than in previous country's reports. These findings should be considered when planning for vaccine trials in our context.

1099

WE'VE GOT STOCK: IMPACT OF IMPROVED SUPPLY CHAIN MANAGEMENT ON MALARIA COMMODITY STOCK-OUT RATES AT THE COMMUNITY LEVEL IN MADAGASCAR

Andritiana Tsarafihavy[1], Thomas Razanakatovo[1], Riana Ramanantsoa[1], John Yanulis[1], Aishling Thurow[2], Thomas Hall[3], Laurent Kapesa[4], Jocelyn Razafindrakoto[4]

[1]Management Sciences for Health, Antananarivo, Madagascar, [2]Management Sciences for Health, Medford, MA, United States, [3]Management Sciences for Health, Arlington, VA, United States, [4]President's Malaria Initiative/United States Agency for International Development, Antananarivo, Madagascar

Community health volunteers (CHV) in Madagascar play an integral role in diagnosing and treating malaria cases in children under five (CU5) in populations living more than five kilometers from a health facility. To offer these services, CHVs need a continuous, adequate supply of essential malaria commodities including rapid diagnostic tests (RDT) and artemisinin-based combination therapy (ACT). However, the lack of a standardized community logistics management system compromised not only the availability of, but also the quality and correct use of products by CHVs. To improve the supply of essential health products for community-based primary health care, the USAID Mikolo Project designed and implemented a commodity logistics management system for CHVs working in eight of Madagascar's 22 regions. The project developed standards, procedures, and tools for selecting, quantifying, and managing commodities and integrated them into a training program on stock management for CHVs, health center staff supporting the CHVs, district and regional health managers, and the national directorate of essential medicines. Following the training, the project provided on-site supportive supervision to monitor and further strengthen the CHVs' skills in stock management and to maximize compliance with the standards. The project also supported monthly meetings between CHVs and health center supervisors to review stock usage data to ensure adequate distribution based on need. With the implementation of this community-based logistics system, the USAID Mikolo Project has witnessed great reductions in ACT and RDT stock-outs: across the eight regions, ACT stock-outs decreased from 20% in 2014 to 7% in 2017 and RDT stock-outs decreased from 13% in 2014 to 6% in 2017. The rate of fevers tested with RDTs by CHVs increased from

61% in 2014 to 86% in 2017, and RDT-confirmed malaria cases treated with ACTs by CHVs increased from 35% in 2013 to 89% in 2017. The greater availability of RDTs and ACTs contributed to better malaria case management practices among CHVs. A scale-up of these monitoring tools could improve stock management and malaria care in other communities.

LESSONS LEARNED FROM DEPLOYMENT OF DHIS2-BASED HEALTH NETWORK QUALITY IMPROVEMENT SYSTEM (HNQIS) OVER 4,000 PRIVATE SECTOR MALARIA PROVIDERS IN MYANMAR

Si Thu Thein, Phone Si Hein, Khun Thiha, Hnin Su Su Khin

Population Services International, Yangon, Myanmar

Private sector health care providers are frequently the only source of healthcare in the most remote communities, where malaria is highest and the reach of public and formal health services is most stretched. In November 2015, Population Services International (PSI), in collaboration with the National malaria control program (NMCP), started the roll out of malaria RDTs among thousands of private sector providers in Myanmar. These providers were trained and equipped to conduct RDTs, and to treat malaria cases in accordance with national guidelines, and to report the results. In 2017, PSI launched the Health Network Quality Improvement System (HNQIS), a DHIS2-based android app to assess provider quality of malaria case management, including RDT testing. In 2017, 4,100 providers from 3,052 villages in 15 regions were assessed with HNQIS. The assessment used a comprehensive checklist, covering diagnosis, treatment, counselling, reporting, stock, etc. Following an assessment, HNQIS automatically calculated a weighted quality score and the provider was classified into one of three different classes: class A (score >80), class B (50-80), and class C (<50). Among the providers, 2622 (63.9%) fell into class A, 1125 (27.4%) into class B, and 353 (8.6%) into class C. In 2017, these providers had conducted 354,632 malaria RDTs, and identified 3915 positive cases (1.1% positivity). Among them, 243,728 (68.7%) were by class A providers, 87,468 (24.7%) by class B, and 23,436 (6.6%) by class C. Class A providers had highest average number of tests (93), and highest positivity rates (1.16%); class B were in middle with an average of 78 tests and 0.7% positivity; and class C at the lowest with an average 66 tests and 0.2% positivity. Differences in quality scores among different provider types and different geographic regions were also observed. Using HNQIS, PSI was able to assess the quality of private sector providers in remote regions spanned across the country and to compare the quality scores against reported testing data. In doing so, PSI could identify the areas for further improvement and allocate the resources more efficiently.

EXPANSION OF MALARIA CONTROL INTERVENTIONS ASSOCIATED WITH THE DECLINE OF ALL-CAUSE CHILD MORTALITY IN THE DEMOCRATIC REPUBLIC OF THE CONGO (DRC) FROM 2005 TO 2015

Ismael G. Nana[1], Johanna Karemere[2], Olivier Kakesa[2], Jacques Emina[3], Joris Losimba Likwela[4], Aboubacar Sadou[5], Mame Niang[6], Michael Humes[7], Yazoumé Yé[1]

[1]MEASURE Evaluation, ICF, Rockville, MD, United States, [2]MEASURE Evaluation, ICF, Kinshasa, Democratic Republic of the Congo, [3]University of Kinshasa, Kinshasa, Democratic Republic of the Congo, [4]National Malaria Control Program, DRC, Kinshasa, Democratic Republic of the Congo, [5]United States President's Malaria Initiative (PMI), United States Agency for International Development (USAID), Kinshasa, Democratic Republic of the Congo, [6]Malaria Branch, Division of Parasitic Diseases and Malaria, United States Centers for Disease Control and Prevention and PMI, Kinshasa, Democratic Republic of the Congo, [7]PMI, U.S. Agency for International Development, Washington, DC, United States

In the Democratic Republic of the Congo (DRC), key malaria control interventions—especially insecticide-treated nets (ITNs)—have expanded in the past decade. Measuring the impact of this increased coverage will inform future strategies of the National Malaria Control Program and its partners. We conducted a plausibility assessment of the potential impact of malaria control interventions. We analyzed trends in all-cause childhood mortality (ACCM), coverage of malaria interventions, and other contextual factors affecting child survival. We used Cox proportional hazard models to examine the effect of ITN ownership on child survival. The analyses used data from the Demographic and Health Surveys (DHS) in 2007 and 2013. National-level household ownership of at least one ITN increased from 9% in 2007 to 70% in 2013. All provinces experienced similar patterns. ITN use increased between 2007 and 2013 among children under five years of age (6% to 55%) and pregnant women (7% to 60%). Owing to limited data, we could not assess trends in parasite prevalence, but the prevalence of severe anemia (<8g/dl) among children ages 6-59 months decreased significantly, from 11% (95% CI: 9%-13%) in 2007 to 6% (95% CI: 5%-7%) in 2013. ACCM declined from 148 to 104 deaths per 1,000 live births between 2007 and 2013. The decline in all-cause mortality was greater among children ages 6-23 months (relative reduction of 36%)—the age group at highest risk for malaria mortality in high endemicity areas—than among children ages 24-59 months (relative reduction of 12%). Cox regression showed that household ownership of at least one ITN was associated with a 24% decrease in the risk of mortality among children under five years of age during the 24-month period before the survey (risk ratio = 0.76, 95% CI: 0.64-0.90). During the evaluation period, indicators of socioeconomic conditions and coverage of some health interventions also improved. However, these improvements alone cannot account for the observed 30% decline in ACCM. Thus, we conclude that malaria control interventions have partially contributed to the decrease in ACCM in the DRC from 2005 to 2015.

1102

METHOD DEVELOPMENT FOR *PLASMODIUM FALCIPARUM* SPOROZOITES PROTEOME INTERROGATION

Alexandra Urman[1,2], Brian Vesely[1], Jennifer M. Kooken[1]

[1]Military Malaria Research Program, Malaria Vaccine Branch, Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]Oak Ridge Institute for Science and Education, Oak Ridge, TN, United States

Malaria is a life-threatening disease that affects millions of people around the world, with *Plasmodium falciparum* causing the highest mortality rate. The US warfighter faces the highest risk when being deployed to malaria endemic regions, compromising the welfare of the soldier, as well as the mission. We have a novel approach to malaria parasite protein discovery with optimized sample preparation, and Mass Spectrometry (MS) analysis. Current pharmaceuticals are becoming less effective, especially with individuals who are G6PD deficient, and there is not an efficacious vaccine for malaria that is FDA approved. In using a MS-based proteomics approach we able to analyze the complete proteomic profile of *Plasmodium* parasites, assessing proteins that are involved in almost every biological pathway. Characterizing the proteomic profile will be advantageous in the deciphering, discovery, and development of new targets for therapeutic intervention. By applying proteomic principles we have optimized a parasite sample prep methodology that gives us a high yield of proteins, in order to discover candidates. We have observed changes in proteomic profile when comparing sporozoites at zero and four hour time points. The comparison of the parasite in various stages and environments reveals unique proteins depending on the protein expression levels. Using PEAKS Studio 8.5 and Proteome Discoverer 2.2 software, we are able to identify families of proteins present during different time points of development in conjunction with changes in abundance. This will allow for the understanding of proteins present, post-translational modifications (PTMs) that have occurred, and find potential new protein candidates for malaria drug and vaccine development.

1103

INCREASING THE NUMBER OF HANGING POINTS TO SPREAD A BED NET REDUCED THE RISK OF *PLASMODIUM* INFECTION AMONG CHILDREN IN VILLAGES ALONG LAKE VICTORIA IN WESTERN KENYA

Noriko Tamari[1], George O. Sonye[2], Beatrice Awuor[2], James O. Kongere[3], Charles O. Gunga[2], Lucy Oketch[2], Fredrick O. Sony[2], Joel Agolla[2], Noboru Minakawa[1]

[1]Institute of Tropical Medicine, Nagasaki University, Nagasaki, Japan, [2]Ability to Solve by Knowledge Project, Mbita, Homa Bay, Kenya, [3]Centre for Research in Tropical Medicine and Community Development, Nairobi, Kenya

Long-lasting insecticidal bed nets (LLINs) are effective to prevent malaria transmission. Nevertheless, malaria is still responsible for the death of several children in Africa. One plausible reason is that bed nets are not properly hung when children do not sleep on a bed. Rectangular bed nets would not be easily fixed at four points in each corner when they are used on the floor in particular, because of the distance to the hanging points and obstacles by household goods. There, the net dose not spread enough, and children's body parts may touch the net or extend out of it, which may increase the risk of infection. We directly observed the sleeping condition of children under 15 years through a cross-sectional study in Gembe east, western Kenya. The data collected included the number of points that fixed their bed nets, whether their body parts touched the net, whether their body parts were completely inside, and whether they slept on the bed or not. Then the children were tested for *Plasmodium* infection using polymerase chain reaction (PCR). The data were analyzed using multiple logistic regression analysis. Of 694 children observed, 510 (73.5%) were sleeping under LLINs. The PCR positive prevalence was 47.1% for net users and 51.6% for non-net users (OR: 2.14 for non-users, 95%CI: 1.40-3.30). Bed nets used on the beds were fixed at more points than those on the floor (OR=1.21, 95%CI: 1.11-1.32). Children's body parts were less likely to be outside or touch the net with increasing the number of hanging points (OR: 0.78, 95%CI: 0.69-0.88). Children whose bodies were completely inside a net had significantly lower prevalence than those who were outside or touched a net (OR: 0.66, 95%CI: 0.44-0.99). The risk of infection decreased with increasing the number of hanging points (OR: 0.52, 95%CI: 0.31-0.88). These results suggest that LLINs should be properly fixed and spread for children to sleep completely inside and prevent infection, and a bed net should be used with a bed.

1104

IMPACT OF INDOOR RESIDUAL SPRAYING (IRS) INTERVENTIONS ON MALARIA INCIDENCE TRENDS IN THE EAST COAST OF MADAGASCAR

Emily MacDonald[1], **Arnaud Rakotonirina**[2], Jean-Desire Rakotoson[2], Timothee Gandaho[2], Eugene Kiti[2], Allison Belemvire[3], Laurent Kapesa[4], Joss Razafindrakoto[2], Mauricette Andriamananjara Nambinisoa[5], Andry Joeliarijaona Rakotorahalahy[5], Ben Johns[1], Djenam Jacob[1]

[1]Abt Associates, Rockville, MD, United States, [2]Abt Associates, Antananarivo, Madagascar, [3]PMI, Washington, DC, United States, [4]PMI, Antananarivo, Madagascar, [5]NMCP, Antananarivo, Madagascar

Between 2014 and 2017, The President's Malaria Initiative (PMI) Africa Indoor Residual Spray (AIRS) Program conducted annual IRS campaigns, using pirimiphos-methyl CS, in three high endemic districts of the eastern regions of Madagascar, to reduce malaria transmission. The overall spray coverage among the eligible structures was above 90% for all campaigns from 2014-2017, with the total number of eligible structures sprayed per district of 53,074 in Brickaville, 83,536 in Fenerive East, and 66,652 in Tamatave II for the most recent IRS campaign in 2017. The AIRS Madagascar team assessed the impact of IRS on the incidence of malaria in these districts by comparing epidemiological data from three sprayed districts with two non-sprayed districts, which present similar malaria transmission patterns. Routine data from community health agents, basic health centers and district health centers were collected from January 2013 through August 2017 and analyzed to assess the impact of IRS. Multiple regression analysis was used to isolate the effect of IRS on malaria incidence using primary data provided by the National Malaria Control Program controlling for variables that influence malaria transmission, such as near surface humidity, rainfall, elevation, temperature, and long-lasting insecticide-treated nets (LLINs) coverage. Malaria incidence in IRS districts was 7.2/1,000 people among all ages in 2013 and 6.0/1,000 in 2016. However, in non-sprayed districts it was 2.6 and 3.2 per 1,000 people in 2013 and 2016, respectively. While the malaria incidence has decreased in the intervention areas in 2016 compared to 2013, data from the control areas showed an increase in incidence in 2016 compared to 2013 pre-spray data. Our assessment showed that IRS alone contributed to a decrease of 10% in malaria incidence among all age groups, which is significant at the 0.001 level. Combining IRS with LLINs contributed to a greater reduction, 30% decrease in malaria incidence. In conclusion, our results suggest that IRS alone or combined with LLINs can continue to be used as key malaria control interventions in high transmission districts of Madagascar.

1105

IMPACT OF SEASONAL MALARIA CHEMOPREVENTION ON MALARIA TRANSMISSION ON TWO SITES OF THERAPEUTIC EFFICACY STUDY IN MALI

Youssouf Diarra[1], Lassina Doumbia[1], Oumar Kone[1], Lansana Sangare[1], Dade Ben Bouye Haidara[2], Vincent Sanogo[3], Bassi Coulibaly[2], Jules Mihigo[4], Erin Eckert[5], Moustapha Coulibaly[2], Etienne Coulibaly[6], Mouctar Diallo[1], Ababacar Maiga[1], Donald Krogstad[7], Ousmane Koita[1]

[1]USTTB, Bamako, Mali, [2]Referral Health Center of Sélingué, Sikasso, Mali, [3]National Malaria Control Program, Bamako, Mali, [4]U.S. President's Malaria Initiative, U.S. Agency for International Development office, Bamako, Mali, [5]U.S. President's Malaria Initiative, U.S. Agency for International Development office, Washington, DC, United States, [6]Referral Health Center of Kolokani, Koulikoro, Mali, [7]Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States

Seasonal Malaria Chemoprevention (SMC) consists of giving a treatment dose of SP/Amodiaquine for 4 consecutive months. We have selected 2 sites, Sélingué in the south of the Sudanese and Missira in the north sudanese regions. SMC consisted of administering the drugs door to door on designated days in August, September, October and November 2017. The first dose of a dispersible co-blister of SP/AQ which was given each month to children between 3 and 59 months. The child's caregiver then provided the AQ tablets on the subsequent 2 days. The objective was to test the efficacy of AL and ASAQ in children <5 years of age in the context of SMC. In order to enroll the 480 study participants, we have followed 5363 children between 3 and 59 months of age targeted for the 4 rounds of SMC. Children with *P. falciparum* uncomplicated malaria with parasitemia ≥1,000 during the 4 rounds of SMC were assigned randomly into the AL and ASAQ arms. We collected from each study participant 2 ml of blood at the times of recruitment and failure. Slides and filter paper blots were made during the 3 days of the drug administration and the follow-up at days 7, 14, 21, 28, 35 and 42. In case of recurrent parasitemia, quinine was used to treat the patient. We have compared the number of screened children for parasitemia and the number of enrolled children in 2016 and 2017 in order to examine the efficacy of ACTs in Mali. Baseline data was collected in 2016 from Sélingué prior to implementation of SMC. Thus in 2017, we enrolled 240 children between August and November. After the completion of SMC, only 75 children out of the remaining 240 were enrolled after screening 6141 children (between December 2017 and March 2018). In contrast, in 2016 we have enrolled 480 children by screening only 3208 in the absence of SMC in Sélingué (between July and December 2016). The Chi square test for trend was performed using GraphPad Prism showed that the impact was marked

on the malaria transmission when the SMC is performed (P< 0.0001). The decrease of malaria cases was similar in both sites where SMC was performed in 2017 (P= 0.7456). This study suggests that SMC may have had a great impact on the malaria morbidity.

1106

QUALITATIVE ASSESSMENT OF LONG-LASTING INSECTICIDAL NETS TO PREVENT MALARIA ON BIOKO ISLAND, EQUATORIAL GUINEA

Julie Niemczura de Carvalho[1], Abdin Noboa-Rios[2], Marisabel Kubiak[2], Linda Tawfik[2], Kenneth Charles Murray[3], Victor Mba Micha Avomo[1], Wonder P. Phiri[1], Matilde Riloha Rivas[4]

[1]Medical Care Development International, Silver Spring, MD, United States, [2]Links Global, Rockville, MD, United States, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom, [4]Ministry of Health and Social Welfare of Equatorial Guinea, Malabo, Equatorial Guinea

This qualitative study sought to examine incentives and barriers to LLIN use, care, and upkeep to inform social and behavior change communication strategies for integrated malaria control. What happened to Permanet 3.0 LLINs supplied via mass distributions, schools, and antenatal clinics? Why did household LLIN ownership decline rapidly after universal distributions? What factors influenced LLIN use, and what caused low rates of use of available LLINs? Restricted randomization was applied to households to find individuals who met inclusion criteria for gender, geography, reported LLIN use or non-use, and pregnancy status. Written informed consent was obtained, and focus groups were recorded. Trained Equatoguinean facilitators used a discussion guide in Spanish to facilitate 7 focus groups designed to maximize diversity across groups. Community-based participatory analysis was used to highlight new themes that emerged each day. Transcripts were prepared and discussion in local languages translated into Spanish, and the authors performed thematic analysis to identify barriers and incentives to LLIN use. Knowledge of LLINs was good and had little impact on use. For the 70% of participants who used LLINs, perceived benefits of LLIN use such as protection against malaria and other vector-borne diseases outweighed barriers. Risk perception was the main factor influencing use: malaria was perceived as a severe illness for pregnant women and children, but not for men. Despite having knowledge of malaria's severity, some participants did not internalize the risk to which they were exposed. Common barriers to use included dissatisfaction with the LLIN product due to design or color, heat, bad odor, pruritus from contact with the net, dirtiness, and discomfort. Non-users considered the relative benefit of LLIN use limited in the context of indoor residual spraying of insecticide and outdoor malaria transmission. Participants recommended strengthening community processes, especially having neighbors promote and reinforce acceptance, use, and proper care of LLINs, and providing regular follow-up of households that received LLINs.

1107

COST EFFECTIVENESS OF PIPERONYL BUTOXIDE (PBO) BED NETS VERSUS PYRETHROID-ONLY NETS IN PREVENTING MALARIA: A FIELD STUDY IN NIGERIA

Donald S. Shepard[1], John U. Odumah[1], Samson T. Awolola[2]

[1]Brandeis University, Waltham, MA, United States, [2]Nigerian Institute of Medical Research, Lagos, Nigeria

Long lasting insecticidal nets (LLINs), being safe and inexpensive, have been the major tool towards halving malaria's burden since 2000. By 2016, 81% of malaria endemic countries with monitoring data reported resistance to pyrethroids. Growing insecticide resistance threatens their ongoing value. In 2017, the World Health Organization concluded that LLINs with a synergist, piperonyl butoxide (PBO), provided additional public health benefit over conventional LLINs alone in areas of moderate insecticide resistance and endorsed them as a new class of vector control products. However, as PBO nets cost 95% more than conventional LLINs ($4.08 vs. $2.09 per net), critics fear that their use could reverse progress towards universal net coverage. This study assesses the cost-effectiveness of a PBO-LLINt compared to pyrethroid-only LLINs in an area with confirmed pyrethroid resistance. Data come from a randomized two-village trial in Nigeria with epidemiological outcomes. After 18 months of observation with no nets, beginning in 2014 residents in the control village received LLINs and those in the intervention village received PBO nets. Both were followed an additional 32 months. The health center recorded and tested all suspect malaria cases from both villages. Impacts on disability adjusted were modeled. The negative binomial regression analyses found that the PBO LLIN reduced symptomatic malaria cases by 33.4% (p<0.01). The incremental cost per net was US $1.99. The incremental cost-effectiveness ratio was US $16 per DALY averted. Even excluding the offsets in treatment costs and health gains, the added economic benefits of PBO nets over conventional LLINS yielded an extraordinary benefit-cost ratio of 85 to 1. Beyond its public health value, PBO LLINs appear to deliver excellent value for a small additional cost in areas of insecticide resistance.

1108

USE OF A RAPID EVALUATION TO IMPROVE GEOGRAPHIC COVERAGE OF HOUSEHOLD REGISTRATION DURING BENIN'S 2017 INSECTICIDE-TREATED BED NET DISTRIBUTION CAMPAIGN; LESSONS LEARNED AND RECOMMENDATIONS

Filemon Tokponnon[1], Virgile Capo chichi[2], Monica Patton[3], Jean Fortune Dagnon[4], Michelle Kouletio[4], Adicath Adeothy[1], Bella Hounkpe Dos Santos[1], Martin Akogbeto[2], Yves Cyaka[5], Alexis Tchevoede[1]

[1]National Malaria Control Program, Cotonou, Benin, [2]Cabinet d'Etude LEADD, Cotonou, Benin, [3]Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, and U.S. President's Malaria Initiative, Cotonou, Benin, [4]U.S. President's Malaria Initiative, U.S. Agency for International Development, Cotonou, Benin, [5]Alliance for Malaria Prevention, Geneva, Switzerland

Complete household (HH) registration (HHR) is key to successful insecticide-treated bed net (ITN) distribution campaigns. In Benin, HHR teams go door-to-door for 10 days to give coupons exchanged for ITNs, provide ITN distribution information, and mark HH (D: registered, DA: absent, DA+: absent on re-visit, DR: refused). To measure real-time HHR geographic coverage and assess quality of ITN distribution information provided, Benin piloted a rapid evaluation in September 2017. Three villages per arrondissement were randomly chosen; in each village a random HH was chosen to start and 10 rural HH or 20 urban HH were systematically chosen per a sampling frame based on the total number of houses per village. Unregistered HH were those without 'D,' 'DA+,' or 'DR' or those with 'D' that had not received a coupon. Successful HHR was defined as 0-5 unregistered HH per 30 HH/arrondissement; more information was needed if 6-8 HH were unregistered; and registration was to be performed again if >8 HH were unregistered. Of 11,670 HH evaluated, 10,967 (94%) reported that HHR teams had visited them; 10,746 (98%) of their HH were marked. Of 703 (6%) HH that reported no HHR team visit, 186 (26%) were marked. Among 10,947 registered HH, 10,837 (99%) received coupons and 1,970 (18%) and 6,568 (60%) reported they received information on ITN distribution dates and sites, respectively. Overall, 342 (89%) of 384 arrondissements had successful HHR with <5 unregistered HH. The rapid evaluation allowed evaluators to measure HHR geographic coverage in real-time; however, unclear communication channels prevented evaluators from providing results directly to HHR teams in the field which delayed HHR remediation. Data on the quality of ITN distribution information provided were likely underestimates because evaluators did not often encounter the same HH members who were visited by HHR teams. We recommend rapid HHR evaluations define clear evaluator/HHR team feedback mechanisms, focus on collecting verifiable data such as coupons and marked HH, and consider evaluators' time and resources when including questions about the quality of ITN distribution information provided.

1109

COMMUNITY FACILITATORS AND BARRIERS TO A SUCCESSFUL IMPLEMENTATION OF MASS DRUG ADMINISTRATION AND INDOOR RESIDUAL SPRAYING FOR MALARIA PREVENTION IN UGANDA

Humphrey Wanzira[1], Susan Naiga[2], Ronald Mulebeke[1], Fred Bukenya[1], Mariam Nabukenya[3], Osborn Omoding[1], Dorothy Echodu[1], Yeka Adoke[4]

[1]Pilgrim Africa, Kampala, Uganda, [2]Infectious Diseases Research Collaboration, Kampala, Uganda, [3]Ministry of Health, National Malaria Control Program, Kampala, Uganda, [4]Makerere University School of Public Health, Kampala, Uganda

There is growing interest to add Mass Drug Administration (MDA) to existing malaria prevention strategies, such as Indoor Residual Spraying (IRS), to accelerate malaria reduction. A successful MDA and IRS requires high population-wide coverage, emphasizing the importance of community acceptance. This study's objectives were to identify community level facilitators and barriers during the implementation of both interventions in a community with a high malaria transmission intensity. This qualitative study was conducted in two sub-counties in Katakwi district. Kapujan sub-county residents received two rounds of IRS and MDA while Toroma residents received only two rounds of IRS. Key informant interviews and focus group discussions were conducted with key influential district and sub-county personnel and community members respectively. Data was analysed using thematic analysis.Transcripts and interview notes from the in-depth interviews were analysed using ausing a coding scheme developed from pre-defined topics together with themes emerging from the data. The Nvivo software programme was used to aggregate the data by codes and to assist with findings presentation. Overall, fourteen key informants were interviewed; four from Katakwi district and five each from Kapujan and Toroma sub-counties. Five focus group discussions were conducted; four with community members (men and women), two in each sub-county and one with medical staff of Toroma health center IV. Community acceptance of MDA and IRS can be improved through community sensitization, appropriate timing of implementation during the low activity dry season, involvement of government and local leadership, use of the competent locally composed team, community knowledge of malaria effects and consequences and evidence of malaria reduction from interventions. Potential barriers included; miss-communication regarding interventions, the strong unpleasant smell from IRS' Actellic and inadequate duration for engagement with the community. These findings can be used as a basis for improving community acceptability for MDA and IRS campaigns in such settings.

1110

KNOWLEDGE, ATTITUDES AND PRACTICES OF MOTHERS CARETAKERS OF CHILDREN AGED 3 TO 120 MONTHS ON OF SEASONAL MALARIA CHEMO PREVENTION IN BOUNKILING HEALTH DISTRICT, SOUTH SENEGAL

Jean Standeur Kaly[1], Youssoupha Ndiaye[2], Adama Faye[3], Mady Ba[2]

[1]Bambey Sanitary District, Bambey, Senegal, [2]Ministry of Health and Social Action Senegal, Dakar, Senegal, [3]University Cheikh Anta Diop Dakar, Dakar, Senegal

Knowledge, attitudes and practices of mothers and caretakers of children aged 3 to 120 months on of seasonal malaria chemo prevention in Bounkiling health district, south Senegal KALY S. N, NDIAYE Y, FAYE A, BA M. The adequate therapeutic coverage of children aged 3 to 120 months targets for seasonal malaria chemoprevention (SPC) is faced with poor administration of both doses of amodiaquine (AQ) by mothers and caregivers (MaC) in Bounkiling Health district. The overall goal was to study the knowledge, attitudes and practices (KAP) of MAC on SMC in this Health District in 2015. A cross-sectional study was conducted; data were collected through a questionnaire addressed to MaC after an informed consent. Data were entered and analyzed using the EPI INFO software version 3.5.3. Results: A total of 396 MaC were enrolled. Their average age was 30.9 years and the average age of children aged 3 to 120 months was 42.9 months. Adequate therapeutic coverage of children was higher 56.8% (n=54) among polygamous MGEs than 18.1% monogamous (18,1%, n=51) (OR=5,93; IC [3,57 – 9,86]). It went from 52.6% (n=10) among MaC who were unaware of the benefits of SMC to 26.0% for MaC who knew about the benefits, (OR = 3.16, IC [1.24-8.01]). Adequate therapeutic coverage was also linked to the type of adverse drug reactions reported; 30.5% (n= 82) among MaC cited vomiting; 17.6% (n= 12) reported sleepiness and 14.8% (n= 4) reported abdominal pain and diarrhea (Chi2 = 6.71, p = 0.03). Improving the adequate therapeutic coverage of children for SMC is essential to achieve malaria elimination in southa Senegal. It is needed to develop strategies for improving full therapeutic coverage.

1111

SETTING THE STAGE TO INTRODUCE A GROUND BREAKING APPROACH TO PREVENT MALARIA IN PREGNANCY IN SUB-SAHARAN AFRICA: BASELINE-READINESS ASSESSMENT FINDINGS FROM DEMOCRATIC REPUBLIC OF CONGO, MOZAMBIQUE, MADAGASCAR, AND NIGERIA

Maya Tholandi[1], Lolade Oseni[1], Anne McKenna[2], Herbert Onuoha[3], Solofo Razakamiadana[4], Elsa Nhantumbo[5], Alain Mikato[6], Elaine Roman[1]

[1]Jhpiego, Baltimore, MD, United States, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [3]Jhpiego, Abuja, Nigeria, [4]Jhpiego, Antananarivo, Madagascar, [5]Jhpiego, Maputo, Mozambique, [6]Jhpiego, Kinshasa, Democratic Republic of the Congo

Uptake of intermittent preventive treatment during pregnancy (IPTp) is unacceptably low across most countries eligible for the intervention in sub-Saharan Africa. Delivery solely through antenatal care (ANC) has yielded suboptimal results. A Jhpiego-led consortium, in partnership with local ministries of health, is implementing the *Transforming IPTp for Optimal Pregnancy* (TIPTOP) project, which supports community distribution of quality assured SP (C-IPTp), complementing delivery at antenatal care (ANC). TIPTOP aims to increase IPTp3 coverage from 19% to 50% of eligible pregnant women in project areas in Democratic Republic of Congo (DRC), Madagascar, Mozambique, and Nigeria. The project, operating from 2017 to 2022, will provide SP, promote community awareness, and support supervision and coordination efforts between health facilities and community health workers (CHWs) to achieve the 50% target. In year 1, a baseline assessment examined facility readiness for MiP management, SP stock, ANC provider knowledge, CHW characteristics and health facility linkages, and health information system (HIS) quality. TIPTOP assessed 140 facilities and interviewed 175 ANC providers and 67 CHW supervisors. The assessment found that among ANC providers, 80% correctly reported that at least three doses of IPTp are recommended, with a low of 65% in DRC and a high of 100% in Mozambique. Sixty-four percent correctly responded that SP should be initiated in the 2nd trimester, with a low of 15% in Mozambique and a high of 88% in DRC. CHWs varied in terms of gender ratio, ratio to pregnant women, and country-specific eligibility requirements, but all had formal linkages with health facilities. Over-reporting of ANC contacts and IPTp service provision is a data quality challenge. HIS in Nigeria and Mozambique record IPTp3 provision, but only at the local, not national, level. Results from the baseline assessment are informing efforts to improve data quality and CHW-facility data flow; and to strengthen provider knowledge through TIPTOP supported trainings. Additionally, implementation has taken into account the variation discovered among the CHW cadre.

SEASONAL MALARIA CHEMOPREVENTION SCALING UP IN MALI: COVERAGE AND IMPACT ON MALARIA BURDERN AND MARKERS OF THE RESISTANCE OF *PLASMODIUM FALCIPARUM* TO SULFADOXINE PYRIMETHAMINE AND AMODIAQUINE

Issaka Sagara[1], Hamma Maiga[1], Mahamadou Kaya[1], Seydou Traore[1], Sanga Goro[1], Moussa Traore[1], Drissa Coulibaly[1], Hamidou Niangaly[1], Abdoulaye Ongoiba[1], Mathias Dolo[1], Khalid Beshir[2], Colin J. Sutherland[2], Paul Snell[2], Diahara Traore[3], Vincent Sanogo[3], Patrice Coulibaly[4], Eric Hubbard[4], Boubacar Dao[5], Ogobara Doumbo[1], Matthew Cairns[2], Abdoulaye Djimde[1], Paul Milligan[2], Alassane Dicko[1]

[1]University of Bamako, Bamako, Mali, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]National Malaria Control Program, Bamako, Mali, [4]Catholic Relief Services (CRS), Bamako, Mali, [5]World Bank, Bamako, Mali

Mali was one of the first countries to introduce Seasonal Malaria Chemoprevention (SMC), starting in one district in 2012, and reaching then nationwide coverage from 2016 in covering all of the 65 districts. From 2014, the (ACCESS-SMC project from 2014-2016 and World Bank from 2016 onwards) were also among the partners of Mali in scaling up the SMC coverage but also was involved in evaluating the impact of SMC in Mali. SMC drugs using Sulfadoxine-pyrimethamine plus Amodiaquine was given to children aged from 3 months to 59 months years old monthly during rainy season up to four months by the community health workers. Up to 2016, SMC drugs distributions were done using fix teams, door-to-door, from 2017 onwards. Cross-sectional surveys were undertaken in 2015, 2016 and 2017 about a month after the 4th and last SMC cycle. A total of 50 clusters were selected with probability proportional to size in 5 districts each year and in each cluster about 20 children aged between 4 months and 7 years were surveyed. To assess the impact of SMC on malaria burden in Mali, nationwide data routine malaria data from 2013 to 2017 were collected. In addition, routine individual malaria data from health center registers as well the birth histories surveys from women were collected in 2016 and in 2018 using tablets PC. The impact of SMC drugs on malaria parasite resistance was assessed using two cross-sectional surveys; in February 2016 before the SMC program starts in the study area and in March 2018, two campaigns/seasons when SMC program started. The proportions of children who received the four cycles of SMC were 38% in 2015, 57% in 2016 and 72% in 2017. The coverage rates were relatively higher in 2017 compared to 2015 and 2016 following the change in distribution method from fixed point distribution to the door-to-door dstribution. Detailed results in SMC distribution coverage and SMC impact on malaria and the impact of SMC drugs on malaria parasite resistance will be available and presented.

1113

IMPACT OF CONSTRUCTION OF SOCIAL HOUSING UNITS ON MALARIA VECTOR ABUNDANCE ON BIOKO ISLAND, EQUATORIAL GUINEA

Liberato Motobe[1], Jose Antonio Mba Nlang[1], Jordan Smith[1], Raul Nguema Ncogo[1], Wonder Philip Phiri[1], Carlos Cortes Falla[1], Guillermo Garcia[2], Godwin Fuseini[1]

[1]Medical Care Development International, Malabo, Equatorial Guinea, [2]Medical Care Development International, Silver Spring, MD, United States

Construction of massive infrastructures that are often associated with urbanization has profound implications on malaria epidemiology and vector control in Africa. In 2017, the government of Equatorial Guinea created new districts on Bioko Island and embarked on the construction of social housing units in these districts. This study evaluated the impact of the construction of the social housing units on vector abundance on Bioko Island. Mosquitoes breeding habitats at the construction sites of 13 new districts were monitored during the construction phase on a weekly basis. Data were captured on the physical characteristics of each breeding habitat, as well as the larval and pupal forms of mosquitoes. Out of the 13 constructions sites in each of the 13 districts, nine construction sites were intervened with the application of a microbial larvicide, *Bacillus thuringiensis israelensis (*VectoBac GR). Two sites in two districts served as controls without the application of the larvicide. Adult mosquitoes were collected using human landing catches in the surrounding communities at both the intervention and control communities. The proportion of breeding habitats with mosquito pupae in the intervention sites dropped from 30% at baseline to an average of 3% after six months of treatment while that of the control sites increased from 0% to an average of 25.8%. A total of 1,651 mosquitoes were collected during this period. 66% were *Anopheles spp*, 20% *Culex spp* and 14% *Aedes spp*. *Anopheles* man biting rates reduced from 5 bites per person per night at baseline in the intervention communities to an average of 2 bites per person per night while that of the control communities increased from zero to an average of 5 bites per person per night. The construction of housing units which led to the increase in vector densities at the surrounding communities was significantly reduced by the application of larvicide. Larval source management as a complementary intervention is necessary at construction sites to reduce vector populations and prevent possible malaria outbreak.

1114

SPATIAL ANALYSIS OF THE ASSOCIATION BETWEEN LLIN COVERAGE AND MALARIA PREVALENCE AFTER A LLIN CAMPAIGN IN A COMMUNITY IN NORTHEAST UGANDA

Chong Kim[1], Dorothy Echodu[2], Humphrey Wanzira[2], Adoke Yeka[3], **Kathryn L. Colborn**[1]

[1]University of Colorado Denver, Aurora, CO, United States, [2]Pilgrim Africa, Kampala, Uganda, [3]Makerere University Medical School, Kampala, Uganda

In 2016, a large-scale malaria intervention trial was implemented in three communities in Uganda. Two communities received several rounds of indoor residual spraying and one community also received several rounds of mass drug administration of antimalarials. All three communities received long-lasting insecticide treated nets (LLINs) after the baseline survey. Since that baseline survey, two additional six-month cross-sectional surveys were conducted, and prevalence was measured using rapid diagnostic tests (RDT) and microscopy. Additional questions were administered at each survey regarding LLIN coverage. In this study, we analyzed the association of LLIN coverage and malaria prevalence rate in the community that received only the LLIN intervention using a geostatistical model to control for spatial heterogeneity. At each survey, approximately 200 randomly chosen households were surveyed between Feb 2016 to Jan 2017. A generalized linear spatial model was fit to household prevalence and LLIN use (measured by nets per person). Malaria prevalence rate decreased by 34% according to RDT and by 18% by microscopy from survey 1 to 3. LLIN use increased 14.3% between survey 1 to 3. On average, a 50% increase in LLIN coverage was associated with a 15.7% (95% CrI: 1.53%-24.6%) reduction in prevalence rate by RDT and 20.3% (95% CrI: 3.11%-37.0%) by microscopy.

1115

THE ASSOCIATION BETWEEN INSECTICIDE-TREATED NETS (ITN) USE AND MALARIA PARASITAEMIA IN CHILDREN UNDER AGE 5 IN THE NORTHERN REGION OF SIERRA LEONE

Musa Sillah Kanu, Thomas Kenneth Ansumana, Nelson Sheku Fofana

National Malaria Control Programme, Freetown, Sierra Leone

Despite many malaria programmatic interventions in the northern region of Sierra Leone malaria parasitaemia remains high. According to the 2016 Sierra Leone Malaria Indicator Survey (SLMIS) malaria parasitaemia in children under age 5 ranges from 21% in the western region to 52% in the northern region. This study set out to determine the association

between the use of insecticide-treated nets (ITN) and malaria parasitaemia among children under five years in the northern region compared to other regions of Sierra Leone. Cross-sectional household survey data from the 2016 SLMIS was used to analyze the results of the malaria microscopy test for children under the age of five years. After controlling for child's age, residence (urban/rural), wealth, and mother's education this study found that children who slept under an ITN the night before the survey were significantly less likely to have malaria as compared to those that did not sleep under an ITN in the other regions (South, Eastern, and Western) of Sierra Leone (OR: 0.70 p-value 0.003). However, in the northern region children who slept under an ITN were less likely to have malaria but the result was not statistically significant (OR: 0.9 p-value 0.5). Based on the findings of this study, further research is needed into the efficacy of ITNs as well as other malaria programmatic interventions in the northern region of Sierra Leone.

1116

MALARIA DEATH SURVEILLANCE IN UGANDA: NOVEL APPROACH TO INITIATE MORTALITY AUDIT IN HIGH PATIENT LOAD FACILITIES

Stella Atugonza[1], **Daniel J. Kyabayinze**[1], Bayo S. Fatunmbi[2]

[1]National Malaria Control Programme, Kampala, Uganda, [2]World Health Organization, Kampala, Uganda

Uganda is one of the malaria high burden countries in the world. The first of three goals of the Uganda Malaria Reduction Strategy is to reduce annual malaria deaths from the 2013 levels to near zero by 2020. Significant (74%) reduction in malaria mortality has been recorded over the past decade. Malaria surveillance including mortality has been adopted as one of the core interventions in the prevention and control of malaria as part of efforts of the National Malaria control Program to achieve zero death due to malaria in Uganda. The objective is to track areas or groups of people that are mostly affected by malaria, identifying underlying factors, and use information to target resources for maximum impact and establish a system for timely data reporting, analysis and use at all target levels by all sectors reporting for both public and private facilities. On a weekly basis surveillance data is extracted from the national database- the District Health Information Systems-DHIS2 and mTRAC; analysis, calling back in all facilities with reported deaths and developing a line list for the confirmed deaths. Supplementary death audits have been done in Hoima, Kabarole and Kiboga District that have persistently reported < 3 death cases due to malaria on a monthly basis. By January 2016, 18/116 districts had an average of 3 death cases due to malaria per month, more pronounced in children under five. Most deaths were attributed to poor health seeking behavior and delayed referrals or access by refugee communities. Through a strengthened effort of the Malaria Control Program and the key stakeholders, behavioral change communication has been scaled up in the affected communities and improved coordination mechanism at district and health facility levels. Health facilities have been supported in terms of capacity building through vigorous integrated malaria management training, improved supply management, Clinical Audits, and data management for program decision making. Currently Malaria mortality has reduced in selected districts with a range of 1-2 deaths per month.

1117

THE EFFECT OF CHLOROQUINE DOSE AND PRIMAQUINE ON *PLASMODIUM VIVAX* RECURRENCE: AN INDIVIDUAL PATIENT POOLED ANALYSIS

Robert J. Commons[1], on behalf of the WWARN Vivax Study Group[2]

[1]Menzies School of Health Research, Darwin, Australia, [2]WorldWide Antimalarial Resistance Network (WWARN), Oxford, United Kingdom

Chloroquine remains the mainstay of treatment for *Plasmodium vivax* malaria despite increasing reports of failure. We investigated the effect of chloroquine dose and adding primaquine on the risk of recurrence, in a range of vivax-endemic settings. A systematic review identified prospective *P. vivax* clinical trials published between January 2000 and March 2017. Principal investigators were invited to share individual patient data, which were pooled using standardised methodology. Multivariable Cox regression analyses with random effects for study site investigated the role of chloroquine dose and primaquine use on rate of recurrence between day 7 and 42. In total, 37 studies and 5,240 patients were included. 2,990 patients were treated with chloroquine alone, of whom 1,041 (34·8%) received a dose below the recommended 25 mg/kg. The risk of recurrence was 10·4% (95%CI 9·3-11·6) by day 28 and 32·4% (29·8-35·1) by day 42. After controlling for age, parasitaemia, relapse periodicity and gender, a 5mg/kg higher chloroquine dose reduced the rate of recurrence by 18% (Adjusted Hazard Ratio (AHR) 0·82, 0·69-0·97; p=0·0210). The greatest reduction was in children aged <5 years (AHR 0·59, 0·41-0·86; p=0·0058). Adding primaquine reduced the risk of recurrence to 1·4% (0·9-2·1) at day 28 and 4·9% (3·1-7·7) at day 42, a rate of recurrence 90% lower than those treated with chloroquine alone (AHR 0·10, 0·05-0·17; p<0·0001). In summary, chloroquine is commonly underdosed in the treatment of vivax malaria. Increasing the recommended dose of chloroquine to 30 mg/kg in children <5 years could reduce substantially the risk of early recurrence when primaquine is not given. Radical cure with primaquine was highly effective in preventing early recurrence and may also improve blood schizontocidal efficacy against chloroquine resistant *P. vivax*.

1118

8-AMINOQUINOLINE ASSOCIATED HEMOLYTIC RISK IN FEMALES HETEROZYGOUS FOR G6PD DEFICIENCY IN *PLASMODIUM VIVAX* ENDEMIC POPULATIONS

Cindy S. Chu[1], Germana Bancone[1], Widi Yotyingaphiram[1], Emily Gerth-Guyette[2], Gwen Ambler[2], Michael Kalnoky[2], Gonzalo Domingo[2], François Nosten[1]

[1]Shoklo Malaria Research Unit, Mae Sod, Tak province, Thailand, [2]Program for Appropriate Technology in Health, Seattle, WA, United States

Plasmodium vivax is estimated to be responsible for over 100 million clinical infections annually. Treatment with 8-aminoquinoline drugs, such as primaquine, can completely clear *P.vivax* parasites and block vector-borne transmission. These drugs can also cause severe hemolysis in patients with glucose-6-phosphate dehydrogenase (G6PD) enzyme deficiency, an X-linked genetic disorder that affects more than 400 million people worldwide. Females who are heterozygous for G6PD deficiency have two populations of red blood cells: one with low G6PD activity and one with high G6PD activity, resulting in intermediate levels of G6PD activity in the majority of women. The risk of hemolysis among those with intermediate G6PD activity levels represents is poorly understood. SMRU and PATH are conducting a randomized controlled trial to associate intracellular G6PD activity to the likelihood of hemolysis following primaquine treatment. 72 total participants will be assigned to one of two treatment arms; each arm will comprise 12 males with normal G6PD levels, 12 females with normal G6PD levels, and 12 females with intermediate G6PD levels (30-80% of normal activity). Arm 1a will receive primaquine for 14 days and Arm 1b will receive chloroquine for 3 days and concomitant primaquine for 14 days. All participants will be healthy volunteers without severe G6PD deficiency, monitored for two weeks after study drug dosing. Blood samples will be taken at regular intervals for hematologic measures, G6PD quantification, and drug level assays. The trial is expected to be conducted from May to September 2018. We will present demographic data of the study population and descriptive statistics of the primary endpoints: absolute hemoglobin reduction and related changes in intracellular G6PD concentration profiles over the treatment course. Data from this trial will be used to better understand the risk of drug-related hemolysis, particularly in females heterozygous for G6PD deficiency with intermediate G6PD activity levels.

1119

ENHANCED SURVEILLANCE FOR CONTROL AND ELIMINATION OF MALARIA IN THE PHILIPPINES

Maria Lourdes Macalinao[1], Jennifer Luchavez[1], Ralph Reyes[1], Alison Paolo Bareng[1], Edelwisa Mercado[1], Inez Andrea Medado[1], Benjamin Palafox[2], Kimberly Fornace[2], Julius Clemence Hafalla[2], Chris Drakeley[2], Fe Esperanza Espino[3]

[1]Research Institute for Tropical Medicine - Department of Health, Muntinlupa City, Philippines, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Asia Pacific Malaria Elimination Network, Singapore, Singapore

A subnational malaria elimination approach is currently implemented in the Philippines, where provinces make use of different strategies depending on the level of malaria endemicity in their area. Despite this, case reporting for surveillance remains to be mainly passive through health facilities, potentially underestimating the country's disease burden. This study aims to develop and establish an integrated surveillance tool for enhanced malaria control and elimination activities. Health facility-based surveys were conducted in Palawan, Occidental Mindoro and Bataan, representing 3 areas of differing disease burden, to assess the magnitude of the proportion of infections missed by routine surveillance. Along with clinical information, electronic mobile-based questionnaires with integrated spatial information on location of residence of patients consulting at health facilities and their companions were also collected. Microscopy and RDT diagnosis were performed on-site, and dried blood spot samples were collected for molecular and serological assays. Current results show that 16% of the malaria cases in Palawan came from companions of health facility attendees (i.e, missed infections), and an additional 6% of cases were detectable only by PCR (i.e. subpatent infections). Molecular characterization suggested that the parasites harbored mostly wild-type alleles in genes associated with drug resistance (96-100% for *pfmdr1, pfcrt* and *K13,* but 0-40% for *pfdhps* and *pfdhfr*). Moreover, mapping the serological prevalence in the 3 sites highlighted spatial patterns of local transmission. Health systems analysis was also conducted to explore if the developed surveillance tool can be integrated and operationalized, and results indicate that the decision will largely depend on the local assessment of its feasibility. The study is continuing to work closely with the National Malaria Program and local government units to discuss how to overcome the barriers to implementation. Enhancing the surveillance using these tools that can be adapted in varying elimination settings could help in achieving a malaria-free Philippines by 2030.

1120

SMALL UNMANNED AERIAL VEHICLES TO COMBAT MALARIA

Zachary A. Ruble[1], Daniel Pack[1], Tom Kline[2], Fredros Okumu[3], Emmanuel Kaindoa[3]

[1]University of Tennessee Chattanooga, Chattanooga, TN, United States, [2]Kline Health Group, Chattanooga, TN, United States, [3]Ifakara Health Institute, Ifakara, United Republic of Tanzania

While we have come a long way in reducing the incidence of malaria through the use of long-lasting insecticide treated mosquito nets (LLINs) and indoor residual sprays (IRS), the use of outdoor based interventions, such as larviciding, in addition to the indoor preventative measures, can decrease, and possibly even eliminate, the number of malaria cases worldwide. It is infeasible, however, to continuously survey for standing water locations in expansive remote areas where malaria cases often crop up. Previous studies have shown small unmanned aerial vehicles (sUAVs) are cost effective in surveying large areas. These studies typically used a single sUAV and required ground personnel to treat identified sites. Multiple sUAVs offer flexibility in mission planning and robustness in mission execution. In this proposed work, we use a team of sUAVs to survey an area for standing water, collect larvae samples, and deploy environmentally friendly larvicide, *bacillus thuringiensis* subspecies *israelensis* (BTI). Sophisticated directional, vision and terrain observation technologies are planned to be integrated to penetrate dense canopy, locate previously hidden water larvae breeding sites, and treat them with BTI. When combined with education, sanitation, extensive use of bed-nets and housing improvements, sUAV's can potentially save thousands of additional lives in Malaria endemic areas. The aerial vehicles are developed at the unmanned systems laboratory on the campus of the University of Tennessee at Chattanooga (UTC). Field trials are planned to take place in the swampy rice paddy terrain of southeast Tanzania. It is anticipated that the partnership between UTC researchers and experienced Malaria entomologists at Tanzania's Ifakara Health Association will result in a new powerful tool in dealing with the anopheles gambaie culprit.

1121

A CRITICAL ENQUIRY INTO THE VARIABILITY OF INSECTICIDAL NET USE IN CAMBODIA

Charlotte Gryseels[1], Melanie Bannister-Tyrrell[1], Rene Gerrets[2], Koen Peeters Grietens[1]

[1]Institute of Tropical Medicine, Antwerp, Belgium, [2]Amsterdam Institute of Social Science Research, Amsterdam, Netherlands

National programs that distribute long-lasting insecticidal nets (LLINs) to people living in malaria-endemic regions are a cornerstone of global malaria control efforts. LLIN programs aim to achieve "universal coverage" of at-risk populations, measured by indicators constructed from questionnaires in Malaria Indicator Surveys. Reductions in malaria incidence that can be achieved through LLINs are usually assumed to have been optimised once universal coverage has been reached. Through an ethnographic exploration of variability in LLIN use in Ratanakiri province in Cambodia, we argue that indicators of universal coverage of LLINs are not sufficiently commensurate with the realities the indicators are intended to measure, and that this limits the suitability of the data to serve policy purposes in a malaria elimination era. We consider this gap between 'net use', in all its permutations in practice, and the numerical representations of such local net use, actually justifies further exploration of strategies to improve LLIN use in subgroups where persisting malaria transmission clusters, rather than diverting resources away from LLIN research in favour of novel technologies to achieve further reductions in malaria transmission. In addition to the commonly used criteria of 'efficacy' and 'effectiveness' when assessing LLINs as a tool for malaria prevention, we propose 'appropriateness' as a third key concept by which to evaluate LLINs. We define 'appropriateness' as the extent to which LLINs as an intervention (referring to their design as well as their distribution) align with the conditions and associated requirements of the contexts in which they are intended to be used. We intend to demonstrate how failure to adapt LLIN interventions to local contexts induces variability in use, which is not measured when intervention impacts are evaluated. We therefore also use the concept of appropriateness as an analytical lens to examine the relation between LLIN interventions and LLIN coverage indicators.

1122

ASSESSING AND IMPROVING THE PERFORMANCE OF THE MALARIA ELIMINATION PROGRAM AT THE SUBNATIONAL LEVEL IN CAMBODIA

Chea Huch[1], Nicolas Savajol[2], Heng K. Pen[3], Panha Kimsean[3], Son Sak[4], Setha Tan[4], Alina Gagu[2], Markus Werner[2], John Hustedt[5], Po Ly[1], Siv Sovannaroth[1], Mony Srey[2], Bun Sour[3], **Colin Ohrt**[2], Rithea Leang[1]

[1]National Center for Parasitology Entomology and Malaria Control, Phnom Penh, Cambodia, [2]Consortium for Health Action, Phnom Penh, Cambodia, [3]Mondulkiri Provincial Health Department, Sen Monorom, Cambodia, [4]Wildlife Conservation Society, Phnom Penh, Cambodia, [5]London School of Hygiene & Tropical Medicine, London, United Kingdom

Cambodia is where drug resistance historically emerges and then spreads. Our study area is in a forest "island" where DHA-piperaquine-resistant

parasites first crossed borders. In Vietnam, we developed methods to rapidly eliminate malaria; we will replicate/extend the methods in Cambodia. An approved research protocol with six objectives is in place; the first three objectives are funded and will be executed April to July 2016. The objectives/brief methods include: 1) Well-characterized malaria patients, malaria transmission *Foci*, reporting and response approaches. Case reporting, investigation and response will be conducted using the current methods compared with a new approach to target people co-exposed in the actual forest transmission *Foci*. 2) Improved case-management for malaria patients. Systems will be developed, tested to document patients completed treatment correctly and were followed-up for late treatment failure. 3) Malaria drug quality monitoring in both public and private sector outlets. Survey and drug testing methods routinely used by the Cambodia Ministry of Health standard operating procedures will be evaluated. For all interventions, a results-based funding model will be tested. Our initial findings based on interviews with provincial health staff, village heath workers and security forces reveal that malaria increased by ~ 2.5 fold in our target area from 2016 to 2017, with a district level annual parasite index (APIs) increasing from ~ 22 to ~ 55. Current usage of insecticide treated nets in forest risk areas appears to be very low. Challenges with antimalarial drug adherence have been identified. Security personnel protecting the forest have been identified as a neglected population, a probable malaria transmission reservoir and a group who can really help malaria elimination personnel understand the situation in high risk areas. We will present study results and present methods to demonstrate malaria, despite very high APIs, can be rapidly eliminated in this area before the current and potentially last drug regimen is lost.

1123

COMMUNITY PERCEPTIONS ON ASYMPTOMATIC MALARIA CARRIAGE FOR UNDERSTANDING ADHERENCE TO REACTIVE CASE TREATMENT IN THE GAMBIA

Fatou Jaiteh[1], Joan Muela Ribera[2], Yoriko Masunaga[3], Joseph Okebe[1], Umberto D'Alessandro[1], Koen Peeters Grietens[3]

[1]Medical Research Council The Gambia Unit at The London School of Hygiene & Tropical Medicine, Banjul, Gambia, [2]PASS Suisse, Neuchatel, Switzerland, [3]Institute of Tropical Medicine, Antwerp, Belgium

Innovative and cost-effective strategies to identify and treat asymptomatic malaria infections are required but remain a challenge. In the Gambia, a transdisciplinary cluster-randomized trial evaluating reactive treatment with a 3-day course of dihydroartemisinin-piperaquine (DHAP) delivered by village health workers (VHWs) to asymptomatic compound contacts of malaria cases was tested. To understand community attitudes towards the intervention, we explored through an anthropological study broadly the socio-cultural representations of asymptomatic disease and specifically asymptomatic malaria treatment. In the pre-trial questionnaire administered, 70% of respondents mentioned malaria could be hidden in the body without symptom appearance. Whilst this may be interpreted as people's comprehension of asymptomatic malaria, qualitative data indicated that respondents had three different interpretations of asymptomatic disease. It was described as a condition where (i) mild symptoms were present but the person could still carry out their daily activities, (ii) symptoms would appear periodically and disappear over the course of the illness and (iii) disease was hidden until symptoms appeared at a certain time. Respondents further mentioned mosquitoes, hot sun and hard work as the triggers for symptom development but this knowledge was surrounded by doubt and uncertainty. As a result of the uncertainty, taking treatment for an asymptomatic condition was perceived acceptable only when the disease status could be confirmed. However with high treatment adherence (92%) reported for the intervention where there was no screening provided for asymptomatic cases, knowledge on asymptomatic carriage was not seen as a crucial reinforcing factor. Adherence to DHAP treatment was seen to reinforced by the perceived protective effect of the medication, the exemplary role of compound heads and the trust placed in the implementing institution and the VHWs. Adherence to reactive case treatment can be improved by employing a systemic approach and engaging the necessary key stakeholders and community structures.

1124

DEFINING THE BOUNDARIES OF LOCAL MALARIA TRANSMISSION TO INFORM TARGETED RESPONSE STRATEGIES IN THE REMAINING HOTSPOTS IN OKAVANGO, NGAMI AND CHOBE MALARIA ENDEMIC DISTRICTS OF BOTSWANA

Ayokunle Abogan[1], Erica Berlin[1], George Shirreff[1], Refilwe Senyatso[2], Styn Jamu[3], Tjantilili Mosweunyane[2]

[1]Clinton Health Access Initiative, Boston, MA, United States, [2]National Malaria Programme, Ministry of Health and Wellness, Gaborone, Botswana, [3]Q Partnership Inc., Harare, Zimbabwe

Malaria transmission in Botswana is highly focal, with 78% of the 1532 locally infected cases confirmed in case-based surveillance between 2013 and 2016 occurring in three out of 28 districts. Botswana has reoriented its program towards elimination since 2010, but the surveillance system has gaps that hinder an understanding of the geographic limits and drivers of transmission. This inhibits deployment of targeted and aggressive interventions, which are critical to increasing efficiency of resources and accelerate efforts towards elimination. To address this surveillance gap the National Malaria Programme (NMP) and Clinton Health Access Initiative (CHAI) conducted a household parasite survey during the peak transmission season from February to March 2018 in Okavango, Ngami and Chobe districts. The study area was divided into 5x5km blocks, and a total of 180 out of a possible 563 were randomly selected according to incidence estimates. In each block, intended sample size was 130 people to assert that prevalence was <5% at 95% confidence. In each household, information on demographics, mobility, malaria history, preventative measures and health facility utilization was collected through a structured questionnaire. In addition, two individuals (one >5 years and one ≤5 years of age) were randomly selected to receive a Malaria Rapid Diagnostic Test (RDT), and provide blood spots on filter paper for future molecular analyses (quantitative polymerase chain reaction (qPCR) and serology). A total of 5503 questionnaires were administered. Initial results show 5 of 7459 individuals tested with RDTs were malaria positive. Out of the surveyed households, 59% had received indoor residual spraying (IRS) in the recent season, and 58% had at least one bednet for every 2 household occupants. The laboratory results as well as questionnaire data will continue to be analyzed, and the outcome will inform the development of high-resolution malaria transmission maps and the identification of malaria transmission drivers. These findings will help inform targeted response such as IRS campaigns and bed net distribution in Botswana.

1125

LIMITED EFFECTIVENESS OF MALARIA CONTROL STRATEGIES IN REMAINING HOTSPOTS IN SOUTH-CENTRAL VIETNAM: AN ANALYSIS OF SOCIAL FACTORS

Thuan Thi Nguyen[1], Xa Xuan Nguyen[1], Hieu Minh Truong[1], Dung Anh Khac Vu[1], Duong Thanh Tran[1], Ky Van Pham[2], Charlotte Gryseels[3], Koen Grietens Peeters[3]

[1]National Institute of Malariology, Parasitology and Entomology, Hanoi, Vietnam, [2]Ninh Thuan Center of Malaria Parasitology and Entomology, Ninh Thuan, Vietnam, [3]Institute of Tropical Medicine Antwerpen, Antwerpen, Belgium

Residual malaria transmission remains in specific hotspots in mountainous areas in south-central Vietnam despite the success of standardized control program to reduce and eliminate transmission elsewhere in the country. A sequential exploratory mixed-methods study was conducted in Ninh Thuan province in 2016-2017 to assess why malaria persists amongst Ra-glai ethnic minority. Preliminary hypotheses from the qualitative strand

were quantified in a cross-sectional survey with 1,957 individuals and 410 household heads. Firstly, Ra-glai territoriality and mobility patterns made it difficult for the malaria control program to access this population, while exposing them to *An.dirus* the main malaria vector in this region. 97.6% of surveyed households owned at least one field in the forest; 48.2% had a hut there where they regularly stayed overnight. Although 92.1% reported sleeping under a mosquito net the night before the survey, only 66.0% of them brought a net when they last stayed overnight in the field or forest. Secondly, despite free of charge health service, 33.4% did not attend public facilities for their recent illnesses. 24% of malaria patients reported to stop medication after 2 days when fever subsided. Factors related to communication were prominent; language barriers, lacking of health education materials in Ra-glai language influenced people's access to public health service. Mobility factors and the therapy choice were stemmed from the complex interethnic relations with Kinh, the dominant ethnicity. Mobility patterns related to subsistence farming revealed social boundaries that were at odds with regulations on forest management and sedentary farming. For the therapy choice, the hierarchical doctor-patient relationship, as a manifestation of the ethnic hierarchy in Vietnam, constrained trust in the health system for Raglai people. This study highlights the limitation of standardized malaria elimination strategies for heterogeneous minority settings and the relevance of understanding social factors in addition to WHO's recommendation for national strategies to include epidemiological stratification.

1126

FEASIBILITY AND ACCEPTABILITY OF A PEER NAVIGATOR-LED MALARIA FOCAL TEST AND TREAT INTERVENTION TARGETING HIGH-RISK POPULATIONS IN SOUTHERN LAO PDR

Emily Dantzer[1], Andrew A. Lover[1], Bouasy Hongvanthong[2], Sophia Hocini[1], Khampheng Phongluxa[3], Rattanaxay Phetsouvanh[4], Adam Bennett[1]

[1]University of California, San Francisco (UCSF), Global Health Group, Malaria Elimination Initiative, San Francisco, CA, United States, [2]Center for Malariology, Parasitology and Entomology (CMPE), Lao PDR Ministry of Health, Vientiane Capital, Lao People's Democratic Republic, [3]National Institute of Public Health (NIOPH), Lao PDR Ministry of Health, Vientiane Capital, Lao People's Democratic Republic, [4]Department of Communicable Disease Control (DCDC), Lao PDR Ministry of Health, Vientiane Capital, Lao People's Democratic Republic

Populations at higher risk (HRPs) of malaria infection in southern Lao PDR share similar occupational, behavioral, and social characteristics that increase their exposure to outdoor-biting mosquitoes. Based on a series of formative assessments in Champasak Province, shared characteristics include routine forest- and field-based work, sleeping outdoors, and frequent travel to local worksites. To engage these often hard-to-reach populations and improve their access to care, we designed a novel focal test and treat strategy (FTAT) employing peer navigators (PNs) to actively seek out HRPs in forested areas, rice fields, and other non-village sites for participation in an intervention comprising the following: demographic and malaria risk factor survey, testing using standard and Alere highly-sensitive RDTs, dried blood spot collection, treatment of positive cases, and GPS tracking of HRP movement patterns. The FTAT intervention is part of a larger community-randomized trial to assess the effectiveness of different targeted test and treat activities to reduce malaria transmission among village residents and HRPs in 56 villages across 14 health center catchment areas. A mixed-method design will be used to assess the capacity, feasibility, and acceptability of PNs to implement FTAT over an 8-month period from March through October 2018. Data collection methods include direct observations of PNs conducting FTAT and interviews and focus groups with a diverse set of stakeholders including HRPs, participating PNs, formal health sector staff, and national and local malaria officials. This assessment will be important to understand and document stakeholder acceptability and PN competencies, motivations, and perceived FTAT challenges and facilitators to inform potential scale-up or adoption of the strategy in the future. As more countries progress towards elimination, identifying evidence-based, community-led strategies to target HRPs and improve their access to malaria services is a priority, and the PN FTAT intervention represents an innovative approach to addressing this gap if found to be effective, feasible, and acceptable.

1127

THE USE OF THAILAND'S MALARIA INFORMATION SYSTEM TO IMPROVE ACCESS AND QUALITY OF MALARIA SERVICES FOR VULNERABLE COMMUNITIES

Suravadee Kitchakarn[1], Prayuth Sudathip[1], Preecha Prempree[1], Deyer Gopinath[2], Felicity Young[3], Darin Kongkasuriyachai[4], Surasak Sawang[4], David Sintasath[5]

[1]Bureau of Vector Borne Disease, Department of Disease Control, Ministry of Public Health, Nonthaburi, Thailand, [2]World Health Organization, Thailand Country Office, Nonthaburi, Thailand, [3]International Development Group, Global Health Division, RTI International, Research Park Triangle, NC, United States, [4]Inform Asia: U.S. Agency for International Development's Health Research Program, RTI International, Bangkok, Thailand, [5]U.S. President's Malaria Initiative, Regional Development Mission for Asia, United States Agency for International Development, Bangkok, Thailand

In 2001, Thailand established malaria posts to provide free community-based malaria testing and treatment services without the need for licensed medical workers. With guidance from the Ministry of Public Health (MOPH), pre-set criteria were used to select malaria post workers to ensure operational consistency across all posts. The MOPH's malaria information system (MIS) was used to help determine where and how long malaria posts should be placed as well as how to monitor the quality of services provided. Individual electronic records of confirmed malaria cases are captured in real-time and active transmission *Foci* are geo-coded on the MIS platform. The system also captures information from case finding and treatment activities, which is used to monitor and evaluate screening activities, including case load, quality of care and compliance with the operational guidelines for each post. Key variables include: date of diagnosis, date of report, parasite species, treatment provided, age, sex, ethnicity, occupation and risk behavior. From 2004–2017, malaria posts tested 828,204 persons and treated 68,966 patients; among these, 8% were children under 5 years of age, 25% were students aged 5-14 years, and 32% were female. About 48% of patients treated by malaria posts were cross-border migrants compared to 20% treated in public hospitals. As the number of confirmed cases decreased from 26,566 in 2004 to 14,664 cases in 2017, the malaria positive rate among migrants seeking treatment also decreased significantly from 12.3% in 2012 to 2.1% in 2017. The expanded role of malaria posts included supervised treatment, behavior change communication, and distribution of long-lasting insecticide-treated bed nets. The Thai MOPH uses the MIS to inform decisions about where to allocate resources for the establishment of malaria posts, which are shown to be critically important in reaching cross-border migrants and other vulnerable populations with malaria testing and treatment services.

IVERMECTIN-BASED MALARIA VECTOR ELIMINATION VIA PERI-DOMESTIC CATTLE TREATMENT IN THE HIGHLANDS OF VIETNAM: EXPLORATORY STUDIES AND VILLAGE-BASED TRIAL

Andrew A. Lover[1], Ian Mendenhall[2], Jeffrey Hertz[3], Nguyen Xuan Quang[4], Huynh Hong Quang[4]

[1]University of California San Francisco, San Francisco, CA, United States, [2]Duke-NUS, Singapore, Singapore, [3]Naval Medical Research Center-

Asia, Singapore, Singapore, [4]Institute for Malariology, Parasitology and Entomology, Quy Nhon, Vietnam

The Greater Mekong Subregion (GMS) has made important progress towards malaria elimination goals, and Vietnam is currently committed to national malaria elimination by 2030. However, some gaps exist, especially in targeting interventions to vulnerable populations at the fringes of national health systems. Ivermectin, an endectocidal drug, has recently emerged as a potential new tool towards malaria elimination, as humans and animals retain blood concentrations that decrease fecundity and are lethal to feeding anopheline vectors. Zooprophylaxis is using large (generally herd) mammals as bait to 'pull' vectors into traps; these alternative feedings then provide passive protection to human populations. High cattle ownership in many rural communities suggests the utility of combining these strategies in an 'attract and kill' approach. This study utilizes semi-field testing, and a community-scale randomized experimental design. It will assess if sufficient densities of ivermectin-treated cattle can drastically decrease vector densities and alter mosquito population compositions in village settings. In Quy Nhon, Vietnam, colonies of *Anopheles dirus* ss and local cattle will be used in a semi-field study to ensure proper drug dosing, quantify impacts of ivermectin on local vectors, and capture blood levels to assess drug pharmacokinetics in local cattle. Thereafter, six villages in Krong Pa district, Gia Lai province, Vietnam will be randomized as control or treatment sites. In intervention villages, the herds of all consenting households will be treated with a 1% ivermectin (at standard veterinary dosing). At intervention and control sites a combination of cattle-baited trapping, human-landing catches, and CDC light trapping will be used to measure anopheline vectors before & after intervention. Reduction in captures from cattle-baited traps will be the primary endpoint; secondary endpoints will be changes in vector composition. Finally, the feasibility and acceptability of the intervention will be assessed. Data collection will occur in the second half of 2018. Category 1: Malaria - Elimination Category 2: Malaria - Entomology

1129

PLASMODIUM FALCIPARUM POPULATION GENOMIC DIVERSITY ALONG THE SLOPE OF MOUNT CAMEROON

Tobias O. Apinjoh[1], Robert V. Nyingchu[1], Rachiel F. Daniels[2], Mary-Carmen Frinwie[1], Ngum Ndeh[1], Judith K. Anchang-Kimbi[1], Hanesh F. Chi[1], Rolland B. Tata[1], Regina N. Mugri[1], Eleanor F. Magha[1], Delphine A. Tangoh[1], Timothy Farell[3], Eric A. Achidi[1], Dan Neafsey[2], Sarah K. Volkman[2], Dyann F. Wirth[2]

[1]University of Buea, Buea, Cameroon, [2]Harvard TH Chan School of Public Health, Boston, MA, United States, [3]Broad Institute, Cambridge, MA, United States

Malaria remains a global concern, especially in sub-Saharan Africa, despite significant investments in control interventions. In some endemic settings, information on the genetic diversity of the parasite, which will inform future vaccine and drug trials is limited. This study characterized the genomic diversity of *Plasmodium falciparum* populations from different altitudinal zones, with a view to identifying population substructure due to differences in parasite prevalence levels. *P. falciparum* infected individuals were enrolled through cross-sectional surveys in 2013 and 2015 from localities at varying altitudes along the slope of mount Cameroon. Malaria parasitaemic blood screened by light microscopy and parasite's genotype determined using a barcode containing a panel of 24 SNPs. Of the 301 participants enrolled, 176 (58.5%) had single (monogenomic) infections while 125 were polygenomic, with complex parasite populations. The proportion of polygenomic infections was high overall (41.6%, 122/293) and increased (p=0.052) in 2015 (46.4%, 77/166) when compared to 2013 (35.3%, 48/136). In 2013, polyclonal infections were highest (p=0.038) in participants from low altitude areas (59.1%, 13/22) when compared to their intermediate (30.4%, 28/92) and high (31.8%, 7/22) altitude counterparts. Principal component analysis of individual allele frequencies did not identify any parasite population substructure accruing to varying minor alleles in time and space. The overall pairwise Fst of parasite populations across the three altitudinal zones and between 2013 and 2015 was low, with at most 3.5% of the overall allelic variation, due to differences between the populations. The overall complexity of infection (COI, 1.35) did not vary with altitude (p=0.106) and time (p=0.161), although it was higher (p=0.022) in participants at low compared to those from intermediate altitude in 2013. These results indicate enormous diversity, a broadly mixing population and no evidence for recent bottlenecks due to enhanced interventions. We are currently using whole genome sequencing to gain higher resolution of these populations.

1130

RISK FACTORS ASSOCIATED WITH MALARIA INFECTION AMONG PATIENTS WHO SEEK HEALTH CARE THROUGH THE PUBLIC AND COMMUNITY SECTORS IN MALARIA ENDEMIC TOWNSHIPS OF AYEYARWADY REGION MYANMAR

Myat Min Tun[1], M. Thin Ko[2], Moe Moe Aye[3], Nan Aung[3], Christopher Lourenco[3], Arnaud Le Menach[3], Aung Thi[2], Sarah Gallalee[3], Jillian Dunning[3]

[1]Vector Borne Disease Control (VBDC) Program, Yangon, Myanmar, [2]National Malaria Control Program, Yangon, Myanmar, [3]Clinton Health Access Initiative (CHAI), Boston, MA, United States

Malaria cases in Ayeyarwady, a delta region in the southwest of Myanmar, have decreased by 86% from 2011 to 2016, but exposure to forested areas may pose an obstacle to continued decline. Out of 26 total townships in the region, Ngaputaw, Pathein, and Thabaung represent 74.4% of the total confirmed cases in 2017(n=2,024). Despite this geographic concentration of cases and perceived link between forest exposure and malaria, limitations of surveillance data prevent a thorough understanding of the risks for contracting malaria in this region. A case control study was conducted to ascertain forest travel patterns and use of preventive methods and to evaluate the influence of these behavioral and occupational patterns on risk of malaria infection. Patients consulting for fever and tested with a rapid diagnostic test (RDT) for malaria were recruited since September 2017 by staff at 17 health facilities and by 24 village health volunteers in the three highest endemic townships. A case was defined as any recruited patient over 2 years old living or working in the three townships with a fever > 38 C and positive malaria RDT. Controls presented to selected points of care with fever but received a negative malaria test. Information was collected including demographics, geolocation of participant home villages, forest travel patterns, and use of preventive methods. A total of 1,227 individuals were sampled with 76 positive cases. The relationship between sleeping in forested areas overnight and confirmed malaria was observed to be a significant risk factor for malaria infection, with an OR of 3.29 (95% CI 1.67, 7.06). Reported ownership of bednets was high but not significantly different between cases and controls, with an OR of 1.03 (95% CI 0.57, 1.93). This study identified critical areas of high malaria burden and provided evidence that extended time in forested areas contributes to malaria risk. Further exploration of risk around forest worksites should include a focus on extended stays, specific occupations, and travel patterns to optimize interventions.

1131

ESTIMATING THE TREATMENT EFFECT IN PARTICIPANTS ACTIVELY SEEKING TREATMENT IN A CLUSTER RANDOMIZED CONTROLLED TRIAL OF TRAINING TEACHERS TO DIAGNOSE AND TREAT UNCOMPLICATED MALARIA IN THEIR LEARNERS

Elizabeth Allen[1], Katherine Halliday[1], Stefan Witek-McManus[1], A. Mtali[2], A. Bauleni[3], D. Ali[4], V. Kachigunda[5], T. Chimuna[6], D. Melody[6], H. Moestue[7], Nathalie Roschnik[8], Simon Brooker[1], D. P. Mathanga[4], Charles Opondo[1]

Technology, Lilongwe, Malawi, [7]Save the Children USA, Washington, DC, United States, [8]Save the Children, London, United Kingdom

In a randomised controlled trial, the effect of an intervention can be estimated by calculating the difference in outcomes between the groups. The 'standard' approach uses an intention to treat analysis (ITT) where all participants are included in the group to which they were assigned, whether or not they received their allocated intervention. An ITT analysis reduces post-randomisation selection bias, and estimates the intervention effect under routine application, its effectiveness. However, an ITT analysis does not estimate efficacy, the effect of an intervention under ideal circumstances. Per-protocol (PP) analysis, which includes only those who receive the treatment they are randomised to, and 'as treated' (AT) analysis according to treatment received, both give biased estimates of treatment effect. One approach, which provides unbiased treatment effect when there is 'non-compliance' is the complier-average causal effect (CACE) which estimates effect among those who comply with the treatment offered. A cluster-randomised trial was conducted in 58 schools in Malawi. The intervention involved training teachers to diagnose and treat uncomplicated malaria in learners using rapid diagnostic tests and artemisinin-based combination therapy as part of a Learner Treatment Kit (LTK). The primary outcome was teacher-recorded school attendance monitored over 50 weeks, estimated using an ITT analysis. Of interest is the treatment effect among pupils who potentially had malaria, and therefore sought at least one LTK consultation during the trial; we consider these pupils to be the compliers. We defined the CACE estimate of treatment as the odds ratio for absenteeism among compliers in the intervention arm relative to potential compliers in the control arm. The ITT analysis provided no evidence of an effect of the intervention on school attendance. However PP and AT analyses suggested that that children who sought LTK consultations were less likely to be absent from school. The CACE estimate suggested a larger effect of the intervention than the ITT analysis and suggested that the intervention might be effective in those who sought treatment.

1132

TOWARDS MALARIA ELIMINATION: DEVELOPMENT AND ROLL-OUT OF AN INTEGRATED SURVEILLANCE SYSTEM FOR MALARIA ELIMINATION IN SOUTH AFRICA, 2018

Ednah R. Baloyi[1], Mbavhalelo B. Shandukani[1], Sameen Babur[2], Craig Davies[2], Rebecca Graffy[2], Bheki Qwabe[3], Gillian Malatje[4], Eric Q. Mabunda[5], Devanand P. Moonasar[6]

[1]National Department of Health, Pretoria, South Africa, [2]Clinton Health Access Initiative, Pretoria, South Africa, [3]KwaZulu-Natal Provincial Department of Health, Jozini, South Africa, [4]Mpumalanga Provincial Department of Health, Nelspruit, South Africa, [5]Limpopo Provincial Department of Health, Tzaneen, South Africa, [6]National Department of Health; University of Pretoria, Pretoria, South Africa

Strengthening the surveillance system has been a fundamental pillar of South Africa's 2012-2018 Malaria Elimination Strategic Plan. South Africa has prioritized upgrading the Malaria Information System (MIS) onto a single web-based platform to consolidate, and replace the legacy assortment of decentralized Access, SQL, and excel databases for disease surveillance and monitoring and evaluation of interventions. In 2016, South Africa began work to upgrade the MIS on a District Health Information System 2 (DHIS2) platform. Improving functional attributes (the upgraded MIS generates required reports and facilitates required analyses for all users) and operational attributes (the upgraded MIS decreases the time spent capturing, cleaning, analyzing and reporting upon data) of the system were critical priorities for design of the platform, together with sustainability and feasibility of implementation at the ground level. The integration of these myriad malaria data streams into a single system will allow for a rapid, routine, and robust picture of malaria at different administrative units. Users will be able to seamlessly analyse and visualize cases and intervention coverage for a given location, as each module shares a common system and framework. In May 2018, roll-out of the upgraded MIS on DHIS2 will begin. The DHIS2-based MIS includes modules for case notification and case investigation, active case detection, *Foci* investigation, and indoor residual spraying, with a vector surveillance module pending. It allows for real-time data capture from Android tablets by users in the field, and real-time analysis of data by users at all levels in the form of tables, charts, and maps. Sharing experiences in the development and identification of key attributes for the new Malaria Information System can provide a model to facilitate best practices for other malaria eliminating countries as well as for case-based surveillance of other diseases.

1133

STRATEGIES FOR INTERRUPTING FOREST-BASED MALARIA TRANSMISSION

Jaline Gerardin, Amelia Bertozzi-Villa, Edward A. Wenger

Institute for Disease Modeling, Bellevue, WA, United States

In many Southeast Asian settings, forest-going is a high-risk behavior for individual malaria infection and community transmission. Interventions applied in villages, such as village malaria workers, bednet distributions, and mass drug campaigns, often fail to reach forest-goers, leading to challenges for elimination programs. Because individuals from multiple villages often visit similar forest areas, forest-going can also connect otherwise distant transmission pools. In this study, we build a mathematical model of a transmission system that includes both villages and forest locations. The model is used to inform how forest transmission and migrant movement can sustain malaria in Southeast Asian settings and to test how likely different intervention scenarios would lead to elimination. We describe the impact of missing forest-goers on the success of standard intervention packages, identify optimal and feasible targeting strategies, and describe what should be done in villages to minimize outbreaks and prevent resurgence given continued importation from forest-goers.

1134

RISK FACTORS ASSOCIATED WITH MALARIA CASES OBSERVED VIA PASSIVE AND REACTIVE CASE DETECTION AFTER TWO YEARS OF INTERVENTIONS AIMING AT ELIMINATION IN SOUTHERN MOZAMBIQUE

Julia Montana Lopez[1], Beatriz Galatas[1], Humberto Munguambe[2], Helena Martí[1], Lidia Nhamussua[2], Wilson Simone[2], Francisco Saute[1], Pedro Aide[2]

[1]Barcelona Institute for Global Health - Centro de Investigaçao em Saude de Manhiça, Manhiça, Mozambique, [2]Centro de Investigaçao em Saude de Manhiça, Manhiça, Mozambique

Since 2015, a malaria elimination pilot program has been undergoing in Magude district. After two years of indoor residual spraying followed by mass drug administration (MDA) of dihydroartemisinin-piperaquine (DHAp), prevalence dropped to 2.6% at the end of the 2016-17 transmission season and a system of reactive case detection (RCD) with focal MDA at the household level was implemented. Using a structured questionnaire, demographic data and data on use of malaria prevention tools was collected from passively-detected cases and their household contacts at the end of the 2017 dry season. Each household contact was tested for malaria by rapid diagnostic test (RDT) and treated with DHAp. Logistic regression models adjusting for household clustering via random effects were used to identify the main risk factors associated with actively or passively detected malaria cases after two years of interventions. Data presented is preliminary. 649 passively-detected cases were followed from August to November 2017. Of their contacts, 2,312 (92.3%) were RDT-negative and 181 (7.3%) were RDT-positive, here defined as actively-detected cases. In comparison with contacts, passively detected cases were more likely to be male (odds ratio=1.62, p=0.02), 5-15 years old (OR=1.31, p<0.01) and to have travelled in the previous 30 days (OR=2.84, p<0.01). They were also more likely to have slept under a net

the night before (OR=1.26, p=0.02) although this may be affected by the fact that the questionnaire was administered 1-3 days after diagnosis. Actively-detected cases were more likely to be 5-15 years old (OR=1.91, p<0.01) and to have travelled in the previous 30 days (OR=2.81, p=0<0.01) compared to RDT-negative contacts. Thus far, travelling and being 5-15 years old seem to be the main risk factors associated with malaria cases after two years of interventions aiming at elimination in the south of Mozambique. Taking into account entomological and climate data may shed new light on further risk factors.

1135

A RIGOROUS AND REPRODUCIBLE BAYESIAN METHOD FOR DETERMINATION OF THE ORIGINS OF MALARIA INFECTION IN AREAS APPROACHING ELIMINATION

Ben Lambert, Sam Bhatt, Thomas S. Churcher

Imperial College London, Oxford, United Kingdom

To maintain political and financial support for malaria elimination it is essential to rigorously evaluate a country's progress. For a country on the cusp of elimination it is crucial to accurately determine the origins of each disease case. Currently there is no clear definition of how NMCPs should do this and classification methods vary between countries. Overestimating the number of imported cases risks hiding pockets of ongoing transmission whilst underestimating the number may waste valuable resources. Here we present a Bayesian method for determining whether malaria was locally acquired or imported from abroad. This approach is applied to case data from a country on the cusp of elimination. The NMCP for the country in question routinely collects travel histories of individuals diagnosed with malaria and classify each case as either: imported, local, or intraported. This classification is investigated in a statistical framework that combines travel histories with epidemiological data from the locations visited, to predict the likely origin of each infection and, importantly, the uncertainty associated with this designation. Our approach indicates that there is considerable uncertainty and possible misclassifications in the origins of infection for many cases in the dataset. This uncertainty is driven by poor understanding of the generation time of malaria and the presence of asymptomatic infections which may have been missed by the local health system. Our analysis highlights the difficulty with determining the origins of infection for countries nearing elimination. Often the patient data routinely collected is insufficient to conclude whether a case is acquired locally or abroad. A benefit of applying the methodology we present here is that this uncertainty can be explicitly expressed and included in summary statistics and future analyses. An additional benefit of this approach would be realised by applying it to data from neighbouring countries approaching elimination. Our approach could then produce real-time fine-scale maps of endemicity to enable targeting of local reservoirs of infection to hasten national elimination.

1136

A COMPARISON OF MALARIA INDICATOR DATA QUALITY WITHIN ZAMBIA'S MALARIA RAPID REPORTING AND HEALTH MANAGEMENT INFORMATION SYSTEMS

Travis R. Porter[1], Marie-Reine I. Rutagwera[2], Prudence Malama[2], Sandi Litia[2], Chris Lungu[2], Busiku Hamainza[3], Mercy M. Ingwe[3], Thomas P. Eisele[1], John M. Miller[2], Jeff Bernson[4], Michael Hainsworth[5]

[1]Tulane University, New Orleans, LA, United States, [2]PATH-MACEPA, Lusaka, Zambia, [3]National Malaria Elimination Centre, Lusaka, Zambia, [4]PATH, Seattle, WA, United States, [5]PATH-MACEPA, Seattle, WA, United States

Recent iterations of Zambia's National Malaria Strategic Plans have increasingly emphasized the importance of timely, accurate malaria surveillance data to inform malaria control and elimination efforts. The Malaria Rapid Reporting (MRR) system was developed to meet the growing need for timely, case-specific malaria surveillance data to supplement data provided by the national Health Management Information System (HMIS). Previous evaluation has described the quality of data submitted by health facilities through the MRR system, generating interest in the comparative reliability of overlapping malaria data available through the HMIS. This analysis examines the consistency between the MRR and HMIS for the same facilities and time periods. Two rounds of routine data quality audits across 14 districts of Southern Province captured malaria indicator data values recorded in health facility paper registers and those submitted to both information systems over 6-month periods of 2014 and Q4 2015/Q1 2016. Using registers for source data verification of system values, preliminary analysis summarized data element accuracy for both systems at each facility over the audited periods and then compared median facility accuracy for each system. In 2014 and 2015, data values reported in the MRR system were closer to those recorded in facility registers (i.e., more accurate) compared with the HMIS [median facility accuracy: 80.2% *vs* 67.9% (2014); 90.3% *vs* 70.6% (2015) for MRR and HMIS systems, respectively]. Overall, both the MRR and HMIS saw improvements to reported data accuracy from 2014 to 2015. Accuracy of MRR and HMIS data improved in most audited districts, though varied widely by facility. Improvements in data accuracy within the MRR and HMIS over the past few years are encouraging, yet differential rates of improvement and lagging quality of HMIS malaria data suggest that further improvements are needed to be on par with the MRR. Continuing analysis will include additional data for Q4 2016/Q1 2017 and explore reporting rates and accuracy within the HMIS and how well health facility characteristics predict similarities in HMIS and MRR data quality.

1137

STRATIFICATION OF MALARIA TRANSMISSION DYNAMICS AND OPTIMAL INTERVENTION PACKAGES IN ZAMBIA AND MOZAMBIQUE

Joshua G. Suresh[1], Beatriz Galatas[2], Prashanth Selvaraj[1], Milen Nikolov[1], Amelia Bertozzi-Villa[1], John Miller[3], Busiku Hamainza[4], Caterina Guinovart[2], Helena Martí-Soler[2], Pedro Aide[2], Francisco Saute[5], Edward A. Wenger[1], Jaline Gerardin[1], Caitlin A. Bever[1]

[1]Institute for Disease Modeling, Bellevue, WA, United States, [2]ISGlobal, Barcelona, Spain, [3]PATH MACEPA, Lusaka, Zambia, [4]National Malaria Control Centre of Zambia, Lusaka, Zambia, [5]Centro de Investigação em Saúde de Manhiça (CISM), Maputo, Mozambique

Elimination of malaria in most endemic environments requires the coordination of time-limited interventions, such as indoor residual spraying (IRS) and insecticide-treated bed net (ITN) distributions, with longer-term investments in surveillance and case management. Given scarce resources, we are motivated to identify the minimal combination of interventions that can reliably achieve elimination in a given malaria context. The choice of optimal intervention package is not universal: It varies geographically as a function of the factors known to influence the efficacy of campaigns, such as historical transmission intensity, population clustering, and importation rates, among others. Any regional optimization of interventions thus requires stratification, the process by which these factors of influence are identified and sub-regions are classified. With this goal in mind, we have employed detailed 1km gridded simulations of two regions—Lake Kariba in southern Zambia, and Magude district of Mozambique—that have both benefited from IRS and ITN campaigns as well as multiple rounds of mass drug administration (MDA). While both regions have experienced dramatic decreases in the incidence of malaria infections, transmission has not been completely interrupted everywhere. Drawing from survey data, we implement the timing and coverage for MDA, ITN, and IRS on a per-grid cell basis. We also implement data-informed migration, treatment-seeking, and reactive case detection. Relative abundances of An. arabiensis and An. funestus vectors are determined by calibrating to observed parasite prevalence and clinical incidence using entomological data as a prior. We then simulate a set of potential intervention scenarios to identify those packages that yield a high probability of interruption in different risk strata. By carrying out this detailed analysis in two sites with different

entomology, climate, hydrology, etc., we are able to identify more general features of the feasibility and impact of various intervention packages in the sub-Saharan context.

1138

PAST, PRESENT AND FUTURE STRATEGIES FOR MALARIA CONTROL IN TANZANIA: OLD AND NEW APPROACHES TOWARDS MALARIA ELIMINATION

Fabrizio Molteni[1], Ally Mohamed[2], Renata Mandike[2], Renata Mandike[2], Sigsbert Mkude[1], Sumaiyya Thawer[1], Manuela Runge[3]

[1]Swiss TPH, Dar es Salaam, United Republic of Tanzania, [2]NMCP, Dar es Salaam, United Republic of Tanzania, [3]Swiss TPH, Basel, Switzerland

In Tanzania, between 2000 and 2017 malaria prevalence has declined from more than 40% to less than 10%. Currently about half of the country is in low endemicity while the rest is in moderate and high endemicity. Malaria heterogeneity has been consistently observed in different geographical and socio-economic strata. People living in rural areas and within the lowest wealth quintile are 5-10 times more affected than those living in urban areas and within the highest quintile. Past: During the past 15 years, evidence based malaria control interventions have been deployed on a massive scale: 71 million ITNs distributed, 6 million households sprayed, 170 million ACT and 100 million mRDT distributed in health facilities. As a result malaria services accessibility and usage increased over the time. Future: the NMCP has identified two major strategic matters: 1) Is the country able to continue charting the way towards malaria elimination with the current interventions? 2) Is the current situation conducive to deploying appropriate intervention packages for specific populations with differing risks: low wealth, low education; hard to reach and resilient to changes areas. At the heart of these two questions is the strategic decision to realistically move towards malaria elimination. At this point the most relevant programmatic matters to be addressed are: universal access to quality, safe, affordable diagnostics and therapeutics; high coverage of preventive services where needed and intensified surveillance and response. Macro and micro-stratification, impact and cost modelling have been developed to support evidence for the country strategic planning towards malaria elimination.

1139

BCG-INDUCED TRAINED INNATE IMMUNITY DURING CONTROLLED HUMAN MALARIA INFECTION

Jona Walk[1], Charlotte L. de Bree[1], Wouter Graumans[1], Rianne Siebelink-Stoter[1], Geert-Jan van Gemert[1], Marga van de Vegte-Bolmer[1], Karina Teelen[1], Cornelus C. Hermsen[1], Rob J. Arts[1], Marije C. Behet[1], Simone J. Moorlag[1], Simone J. Moorlag[1], Annie S. Yang[1], Reinout van Crevel[1], Peter Aaby[2], Quirijn de Mast[1], André J. van der Ven[1], Christine Stabell Benn[2], Mihai G. Netea[1], Robert W. Sauerwein[1]

[1]Radboud University Medical Center, Nijmegen, Netherlands, [2]Statens Serum Institut, Copenhagen, Denmark

Recent evidence suggests that certain vaccines, including Bacillus-Calmette Guérin (BCG), can induce changes in the innate immune system with non-specific memory characteristics, termed 'trained immunity'. We performed a randomized, controlled clinical trial in 20 healthy male and female volunteers to evaluate the induction of immunity and protective efficacy of BCG vaccination against a controlled human malaria infection (CHMI). Earlier and more severe clinical symptoms in BCG vaccinated volunteers were associated with heterologous, memory-like monocyte and (innate) lymphocyte re-activation that correlated with reduced parasitemia at 5 weeks post CHMI. These findings demonstrate for the first time that BCG vaccination induces trained immunity with functional activity against an unrelated human pathogen *in vivo*. It forms a strong impetus to further explore its potential in the clinical development of a rational malaria vaccine strategy.

1140

IDENTIFICATION OF *PLASMODIUM* GAPDH VACCINE ANTIGENS THAT TARGET SPOROZOITE LIVER INVASION

Sung-Jae Cha[1], Kyle J. McLean[2], Marcelo Jacobs-Lorena[1]

[1]Johns Hopkins University, Baltimore, MD, United States, [2]Massachusetts Institute of Technology, Cambridge, MA, United States

Malaria sporozoite liver infection is an essential step for parasite development in its mammalian host. Previously, we used a phage display library to identify mimotope peptides that bind to Kupffer cells and competitively inhibit sporozoite-Kupffer cell interaction. These peptides led to the identification of a Kupffer cell receptor - CD68 - and a *Plasmodium* sporozoite ligand - glyceraldehyde-3-phosphate dehydrogenase (GAPDH) – that are required for sporozoite traversal of Kupffer cells and subsequent infection of hepatocytes. Here we report that the C-terminal end of *Plasmodium* GAPDH interacts with the Kupffer CD68 receptor and identify two epitopes within this region as candidate antigens for the development of a pre-erythrocytic malaria vaccine.

USE OF NSAIDS FOR MITIGATION OF MALARIA-ASSOCIATED SYMPTOMS AT HIGH DOSES OF SANARIA PFSPZ CHALLENGE UNDER CHLOROQUINE PROPHYLAXIS

David M. Cook[1], Agnes Mwakingwe-Omari[1], Sara A. Healy[1], Jacquelyn Lane[1], Susan Pfeiffer[1], Sahand Kalhori[1], Chalres Wyatt[1], Irfan Zaidi[1], Tooba Murshedkar[2], Adam Ruben[2], Sumana Chakravarty[2], Anita Munoj[2], Anusha Gunasekera[2], Kim L. Sim[2], Peter F. Billingsley[2], Eric R. James[2], Thomas L. Richie[2], Stephen L. Hoffman[2], Patrick E. Duffy[1]

[1]National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [2]Sanaria, Rockville, MD, United States

Immunization with 3 doses of ~$5x10^4$ aseptic, purified, cryopreserved, infectious *Plasmodium falciparum* (Pf) sporozoites (SPZ) (Sanaria® PfSPZ Challenge) under chloroquine chemoprophylaxis, a strategy termed PfSPZ-CVac, achieved 100% (9/9) and 80% (4/5) vaccine efficacy (VE) in malaria-naïve volunteers against homologous controlled human malaria infection (CHMI) at 10 weeks after last vaccine dose. Achieving a comparable level of VE against heterologous CHMI, which may be more reflective of field transmission of heterogeneous strains of Pf, may be more difficult. While higher doses of PfSPZ Challenge may improve VE against heterologous CHMI, moderate and severe symptoms associated with Pf infection have been a limiting factor in some trials. Reducing the severity of malaria-associated symptoms would significantly improve the tolerability and therefore the acceptability of PfSPZ-CVac. An ongoing clinical trial (NCT03083847) at the NIH Clinical Center is evaluating whether 3 doses of $2x10^5$ PfSPZ of PfSPZ Challenge confer protection against heterologous CHMI in healthy malaria-naïve adult volunteers taking chemoprophylaxis. A pilot group of 4 volunteers received $2x10^5$ PfSPZ of PfSPZ Challenge, and they subsequently experienced 19 Grade 1 symptoms, 5 Grade 2 symptoms, and 3 Grade 3 symptoms, including fever, chills, and myalgia, primarily 7 and 8 days after administration of PfSPZ Challenge when parasitemia was highest. In an effort to improve tolerability during the main phase of the study, non-steroidal anti-inflammatory drugs (NSAIDs) were given prophylactically to 5 volunteers as scheduled medications, even in the absence of any malaria-associated symptoms, on days 7-8 post-PfSPZ Challenge after first vaccination. During this time, there were 23 Grade 1 symptoms, and no Grade 2 or 3 symptoms reported in the group using prophylactic NSAIDs. These findings suggest that the use of prophylactic NSAIDs may reduce or eliminate moderate and severe malaria-associated symptoms if employed during future PfSPZ-CVac trials, furthering the effort to develop an effective and tolerable malaria vaccine.

1142

DISTRIBUTION OF PFSPZ VACCINE TO TRAVEL MEDICINE CLINICS

Eric Robert James[1], Adam Ruben[1], John Phillips[2], Bret Bollinger[2], G. John Morris[3], Phil Vanek[3], Martin P. Grobusch[4], L.W. Preston Church[1], Thomas L. Richie[1], Peter F. Billingsley[1], B. Kim Lee Sim[1], Anita Manoj[1], Stephen L. Hoffman[1]

[1]Sanaria, Rockville, MD, United States, [2]Cryoport, Irvine, CA, United States, [3]GE Healthcare, Marlborough, MA, United States, [4]Center for Tropical Medicine and Travel Medicine, Amsterdam, Netherlands

In preparation for licensure of Sanaria® PfSPZ Vaccine, plans are progressing for its distribution to travel medicine clinics (TMC) in the USA and Europe. PfSPZ Vaccine is a live attenuated, metabolically active, non-replicating *Plasmodium falciparum* (Pf) whole sporozoite (SPZ) vaccine that, because PfSPZ are eukaryotes, is cryopreserved and stored in liquid nitrogen (LN2) vapor phase (LNVP). LN2/LNVP cold chains have been used routinely for decades to distribute veterinary reproductive products and vaccines. The new chimeric antigen receptor T-cell (CAR-T) therapies have accelerated LNVP cold chain growth. There are many scenarios for PfSPZ Vaccine distribution to TMCs, ranging from sporadic as-needed shipments to small TMCs serving occasional travelers, to ongoing, biweekly shipments to medium-sized TMCs serving travelers frequently, to maintaining an in-clinic vaccine stock for large, centralized TMCs serving hundreds of travelers/week. The LNVP cold chain utilizes cryoshippers to transport vaccine and as temporary in-clinic vaccine repositories. In development are new electric LN2-free cryoshipper/storage units suitable for some TMCs and semi-automated dry thawing devices. Vaccine, in 0.8 mL cryovials, is packaged in two formats for different sized cryoshippers. Cryoshippers with static hold times ranging from 10 to 53 days, customized for PfSPZ Vaccine, will distribute vaccine payloads ranging from 36 doses (7-12 regimens) to 1,296 doses (259-432 regimens). From two dedicated PfSPZ Vaccine distribution centers in Europe and the USA, a good distribution practices (GDP) hub-and-spoke shipping system will deliver vaccine direct to TMCs as needed with continuous-access, real-time, GPS-based tracking and monitoring (including payload and external temperatures, pressure, tilt, shock) using preferred logistics carriers. Cryoshippers will be cycled back to the hub for recharging and restocking. Models for the different scenarios developed from already extensive experience serving PfSPZ clinical trials will be presented.

1143

RADIATION IMPAIRS MOVEMENT OF *PLASMODIUM FALCIPARUM* MALARIA SPOROZOITES IN HUMAN SKIN

Fijs van Leeuwen[1], Beatrice Winkel[1], Matthias van Oosterom[1], Diego Staphorst[1], Clarize de Corne[1], Severinne chevalley[1], Koen Dechering[2], Blandine Franke-Fayard[1], Meta Roestenberg[1]

[1]Leiden University Medical Center, Leiden, Netherlands, [2]TroplQ, Nijmegen, Netherlands

Given the resurgence in global malaria cases and deaths, the need for a highly efficacious malaria vaccine for *Plasmodium falciparum* (Pf) is more pressing than ever. Vaccines based on the administration of live-attenuated sporozoites (spz), have been shown to fully protect malaria-naïve individuals and the radiation-attenuated sporozoite vaccine (Sanaria Inc) is now entering phase 3 clinical development. Because migration to the liver is key to the induction of protection in these vaccines, they need to be administered by mosquito bite or intravenously. To date migration of Pf spz in human skin remains wholly uncharacterized in the context of wild type as well as attenuated parasites. Using confocal microscopy movie material was obtained on spz movement *in vitro* and following syringe-based administrations in *ex vivo* human skin explants. To analyse the full migrational complexity of the spz we have developed custom image analysis software able to quantify key motility parameters of spz migration. We compared the movement of different vaccine formulations by recording the motility of wild-type and radiation-attenuated GFP-expressing Pf spz. Image analysis showed that the spz motility was significantly influenced by the human skin environment and was completely different from *in vitro* movement patterns. In human skin the velocity was lower and related to the movement pattern. Compared to *in vitro*, movement patterns were more complex and showed a higher degree of displacement. The tissue morphology appeared to drive directional migration. A quantitative comparison of wild-type and radiation-attenuated spz displayed indicted radiation increases the percentage of sharp turns, reduces the straightness index, and decreases the velocity. Using our custom software we have been able to show that the formulation of live-attenuated vaccines is crucial for the migration of spz in human skin. This provides a novel tool for future vaccine refinement.

[1]Ifakara Health Institute, Bagamoyo, United Republic of Tanzania, [2]Equatorial Guinea Malaria Vaccine Initiative, Malabo, Equatorial Guinea, [3]Swiss Tropical and Public Health Institute, Basel, Switzerland, [4]Sanaria Inc, Rockville, MD, United States, [5]Ministry of Health and Social Welfare, Malabo, Equatorial Guinea, [6]Medical Care Development International, Silver Spring, MD, United States, [7]Medical Care Development International, Malabo, Equatorial Guinea

Malaria continues to be a serious public health problem in most of the developing world. The advanced pre-erythrocytic malaria vaccine candidates produced moderate efficacy in malaria pre-exposed population. Neutrophils and monocytes are important in vaccination as they produce initial cytokines that determine the outcome of the adaptive immune response. Our understanding of the role of human neutrophils and monocytes in *Plasmodium falciparum* (Pf) pathogenesis is limited to epidemiological studies of natural infection. In these studies, establishing the relationship between neutrophils, monocytes and times of malaria infection has been challenging. Controlled human malaria infection (CHMI) provides a platform to study malaria infection and pathology in a well-controlled setting. We have completed a CHMI in healthy Equatoguinean young adults who previously received aseptic, purified, live, radiation-attenuated, cryopreserved Pf-NF54 sporozoites or low doses of non-irradiated, infectious NF54 PfSPZ administered under chloroquine chemoprophylaxis. Whole blood was collected to determine heamatological parameters at baseline, 2, 9, 13, and 28 days post-CHMI. Malaria parasite monitoring was performed by qPCR and thick blood smear (TBS) on a daily basis from day 8 post-CHMI until onset of blood stage parasitemia. Subjects were immediately treated with artemether-lumifantine after infection was confirmed by both qPCR and TBS or at day 28 post-CHMI. Serum for anti-Pf circumsporozoite (CSP) antibodies was also collected on baseline and 28 days post-CHMI. We will present data on potential relationships of neutrophil and monocyte counts measured by automated haematology analyzer with regard to the prepatent period and Pf-CSP antibody titer during CHMI of Equatoguinean young adults. This study will generate an insight on potential role of neutrophils and monocytes in modulating protection during CHMI and how such knowledge could be translated into improved malaria vaccine design and immunotherapy.

1145

LONG TERM EFFICACY OF A THREE-DOSE REGIMEN OF RADIATION AT TENUATED *PLASMODIUM FALCIPARUM* NF54 SPOROZOITES (PFSPZ VACCINE) IN HEALTHY MALIAN ADULTS

Mahamadou S. Sissoko[1], Sara A. Healy[2], Abdoulaye Katile[1], Agnes Mwakingwe-Omari[2], Irfan Zaidi[2], Zonghui Hu[3], Bourama Kamate[1], Kourane Sissoko[1], Cheick O. PfSPZ Vaccine is composed of radiation-attenuated (non-replicating), aseptic, purified, cryopreserved *Plasmodium falciparum* (Pf) sporozoites (SPZ) that are administered by direct venous inoculation (DVI). A double-blind, randomized Phase 1/2 clinical trial of PfSPZ Vaccine was conducted in Mali, West Africa, using a regimen of 1.8 x 10^6 PfSPZ given at 0, 2 and 4 months. This trial demonstrated a similar level of protective efficacy against naturally occurring *P. falciparum* infection (24% by proportional and 51% by time-to-event analysis) to that previously reported (29% by proportional and 52% by time-to-event analysis) with a 5 dose regimen of 2.7 x10^5 PfSPZ Vaccine tested in Malian adults. Here, we explored the duration of the protective activity of the 3-dose regimen in a second year of follow up. We re-enrolled all 44 eligible PfSPZ Vaccinees as well as 44 eligible controls, along with 26 additional controls from the area that matched by group with the PfSPZ Vaccinees according to village, age, and sex and according to the same inclusion criteria as the original vaccine cohort. Baseline characteristics, such as hemoglobin type and parasitemia status (blood smear and PCR), were collected and all subjects were treated with a full treatment course of artemether/lumefantrine at the time of enrollment to clear any existing parasitemia. No investigational vaccine product was given. Study participants were seen actively every 14 days for a total of around 6 months of the malaria transmission season. The protective efficacy results and immune responses measured during this second transmission season will be presented.

1146

EXPERIENCE IN MANAGING SANARIA®PFSPZ VACCINE: A RANDOMIZED, DOUBLE-BLIND, PLACEBO CONTROLLED PHASE 1 CLINICAL TRIAL TO EVALUATE THE SAFETY AND IMMUNOGENICITY OF PFSPZ VACCINE IN MALARIA-EXPERIENCED ADULTS IN BURKINA FASO

Edith C. Bougouma[1], Issiaka Soulama[1], Eric R. James[2], Yonas Abebe[2], Alphonse Ouedraogo[1], Alfred Tiono[1], Roland Koutiebou[1], Albert Gnima[1], Jean M. Kabore[1], Peter F. Billingsley[2], Anita Msnoj[2], Thomas L. Richie[2], Kirsten E. Lyke[3], Christopher V. Plowe[3], Walter Jones[4], Mathew B. Laurens[5], Stephen L. Hoffman[6], Sodiomon B. Sirima[1]

[1]Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, [2]Sanaria Inc., Rockville, MD, United States, [3]Duke Global Health, Durham, NC, United States, [4]Parasitic and International Programs Branch, Division of Microbiology and Infectious Disease, National of Allergy and Infectious Disease, Bethesda, MD, United States, [5]Division of Malaria Research for Global Health, Baltimore, MD, United States, [6]Sanaria Inc, Rockville, MD, United States

Proper study investigational vaccine product management is critical for clinical trial conduct and for generating valid study results. PfSPZ Vaccine comprised of metabolically active, non-replicating, cryopreserved, *Plasmodium falciparum* (Pf) sporozoites (SPZ), is reported to be safe and highly protective against Pf controlled human malaria infection in malaria-naive individuals. Experiences gathered managing a double-blind Phase 1 clinical trialqre repoprted here. Cryovials containing 45X10^4 PfSPZ were stored in a liquid nitrogen vapor phase dry shipper at CNRFP and transported from Ouagadougou to the study site in Balonghin, 45 minutes by road. 792 cryovials of PfSPZ Vaccine, 35 vials of PBS and 75 vials of NaCl, were received from the manufacturer in three, two, and three shipments, respectively. Shipments averaged of seven days in transit. No temperature excursions were recorded for placebo and diluent (15°C to 25°C) or vaccine in LNVP (below -150°C) during shipping or storage, However, the post last inoculation , one excursion for vaccine occurred due to the simultaneous lack of LN2 at the research site and at both localLN2 suppliers in Ouagadougou. A total of 703 cryovials were used for vaccine preparation of vaccine syringes without loss, and the remaining 89 were returned to the manufacturer. One study pharmacy protocol deviation was reported at the first dose: an incorrect treatment was given to one volunteer that was corrected.. Doses were prepared to standard operating procedures. Mean cryoshipper temperature at opening to retrieve cryovials for dose preparation was-187.43 ± 2.89º C, and ranged from (-145.5 to-197.9 °C) during shipment from the USA to Ouagadougou, Burkina Faso. The mean time for syringe preparation for injection was 8:00± 0.0007minand the mean time from cryovial thawing to completing injection was 20.66 ±0.005min.More than 99.95% of the 240 total vaccine and placebo administrationsrequired only one syringe preparation. This study shows that vaccine storage, handling, preparation and administration, according to rigorous pharmacy and clinic SOPs are possible in a resource-limited setting.

1147

PROTECTIVE EFFICACY OF THE PFSPZ VACCINE AGAINST ENDEMIC MALARIA AMONG MALARIA-EXPERIENCED ADULTS IN BURKINA FASO

[1]Division of Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, [2]Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, [3]Sanaria, Inc, Rockville, MD, United States, [4]Duke Global Health Institute, Duke University, Durham, NC, United States, [5]The Emmes Corporation, Rockville, MD, United States, [6]Parasitic and International Programs Branch, Division of Microbiology and Infectious Diseases, National Institute of Allergy and Infectious Diseases, U. S. National Institutes of Health, Bethesda, MD, United States

PfSPZ Vaccine is composed of radiation-attenuated (non-replicating), aseptic, purified, cryopreserved *Plasmodium falciparum* (Pf) sporozoites (SPZ) that are administered by direct venous inoculation (DVI) and have proven in 15 trials in the US, EU and Africa to be safe, immunogenic and protective against both endemic Pf and controlled human malaria infection. Five doses of 2.7 x 10^5 PfSPZ administered over 20 weeks demonstrated 52% vaccine efficacy (VE) by time to event and 29% by proportional analysis against naturally occurring infection in Malian adults. The current trial is testing 3 doses of 2.7 x 10^6 PfSPZ administered at 0, 8 and 16 weeks to Burkinabe adults as a more practical regimen. In the first part of the study, an open label, dose-escalation assessment of safety and immunogenicity, four staggered cohorts of 8 participants received two DVI doses of 4.5x10^5, 9x10^5, 1.8x10^6 or 2.7x10^6 PfSPZ at 12-14 week intervals. All doses were safe and well tolerated, and 2.7x10^6 PfSPZ induced the greatest median ratio of post- to pre-immunization anti-Pf circumsporozoite protein (PfCSP) antibody levels of 6.7 (ratio of OD 1.0 post- to pre-immunization). In the second part of the study, 80 individuals were randomized 1:1 in a double-blinded manner to receive 3 DVI doses

of 2.7 x 10^6 PfSPZ or saline placebo at 8-week intervals, with presumptive clearance of parasitemia before the first and last doses using 7 days of artesunate monotherapy. Participants were then actively and passively followed for 24 weeks during the peak malaria transmission season to assess vaccine efficacy (VE). The vaccine was safe and well tolerated. VE against Pf infection by microscopy was 37.7% (95%CI 6.8-68.7%, p=0.017) by proportional analysis (primary VE estimate) and 47.1% (95%CI -3.8-73.1%, p=0.064) by time to event analysis. PfSPZ Vaccine demonstrated significant protection in malaria-experienced African adults against Pf throughout an entire malaria transmission season. Follow-up for part two continues through the 2018 malaria season to assess the durability of immune responses and protection.

1148

SAFETY, TOLERABILITY AND PROTECTIVE EFFICACY OF PFSPZ-CVAC AGAINST ENDEMIC MALARIA AMONG MALARIA-EXPERIENCED ADULTS IN MALI

Drissa Coulibaly[1], Abdoulaye K. Kone[2], Karim Traore[2], Kirsten E. Lyke[3], Christopher V. Plowe[4], Yonas Abebe[5], Jessie K. Kennedy[6], Gail E. Potter[6], Effie Nomicos[7], Gregory A. Deye[7], Thomas L. Richie[5], Eric R. James[5], B. K. Sim[5], Stephen L. Hoffman[5], Ogobara K. Doumbo[2], Mahamadou A. Thera[2], Matthew Brent Laurens[3]

[1]Malaria Research and Training Center, University of Sciences, Techniques and Technologies, Baltimore, MD, United States, [2]Malaria Research and Training Center, University of Sciences, Techniques and Technologies, Bamako, Mali, [3]Division of Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, [4]Duke Global Health Institute, Duke University, Durham, NC, United States, [5]Sanaria, Inc, Rockville, MD, United States, [6]The Emmes Corporation, Rockville, MD, United States, [7]Parasitic and International Programs Branch, Division of Microbiology and Infectious Diseases, National Institute of Allergy and Infectious Diseases, U. S. National Institutes of Health, Bethesda, MD, United States

PfSPZ-CVac is a vaccination strategy for malaria that involves concurrent administration of fully infectious *Plasmodium falciparum* (Pf) sporozoites (SPZ) (PfSPZ Challenge) and a partner drug to kill the parasites *in vivo*. When the partner drug is a selective blood schizonticide such as chloroquine (CQ), the PfSPZ infect hepatocytes, replicate many thousand fold, are released into the blood stream but are then rapidly killed. PfSPZ-CVac using weekly CQ administration was tested in Germany in 3 groups of malaria-naïve adults receiving 3 doses by direct venous inoculation (DVI) at 4 week intervals of 3.2x10^3, 12.8x10^3 or 51.2x10^3 PfSPZ, respectively, and 3/9 (33%), 6/9 (67%) and 9/9 (100%) were sterilely protected against homologous controlled human malaria infection 9-10 weeks after immunization. We aimed to assess the safety, immunogenicity and protective efficacy of PfSPZ-CVac against naturally acquired Pf in malaria-experienced Malian adults in a randomized, controlled, double blind clinical trial. Participants (n=62) were randomized to receive 3 doses of 2.048x10^5 SPZ of PfSPZ Challenge (NF54) - a 4-fold higher dose than Germany - or normal saline placebo by DVI at 4 week intervals while taking weekly CQ. A Safety and Monitoring Committee reviewed data collected up to 12 days after first injections before subsequent doses were given. Participants received a seven-day curative oral artesunate monotherapy regimen after last injections and just before the 2017 malaria transmission season start, but did not receive antimalarial therapy before immunizations. Participants were then actively and passively followed for 6 months to assess efficacy against Pf infection. The vaccine strategy demonstrated a favorable tolerability profile, with no safety signal. Analysis of efficacy against Pf infection by microscopy and by PCR in those who were and were not infected at the time of immunizations, and analyses of immunogenicity by anti-PfCSP antibody ELISA will be presented. Follow-up for extended efficacy and safety continues through June 2018 to assess duration of immunogenicity and protection against infection.

1149

NO SEX, NO DIFFERENCE: *PLASMODIUM FALCIPARUM* INFECTIONS IN VIRGIN AND MATED *ANOPHELES STEPHENSI*

Matthew Warndorf, Tao Li, Yingda Wen, Sumana Chakravarty, Thomas Pike, Asha Patil, B. Kim Lee Sim, Peter F. Billingsley, Abraham G. Eappen, Stephen L. Hoffman

Sanaria Inc., Rockville, MD, United States

Sanaria® PfSPZ Vaccine and PfSPZ-CVac have been highly protective in clinical trials in the US, Germany, and Africa. These vaccines are composed of aseptic, purified, cryopreserved *Plasmodium falciparum* (Pf) sporozoites (SPZ), and are manufactured using aseptically grown *Anopheles stephensi* mosquitoes. Even though the production of aseptic *A. stephensi* is highly efficient and reproducible, only females are needed for the production of PfSPZ. Male mosquitoes are considered a byproduct of the process and compete for essential resources; growth medium and nutrients in larval containers and resting space in adult chambers. Virgin females of some *Anopheles spp.* will not freely take a blood meal or will take a smaller blood meal, thus limiting uptake of Pf gametocytes and development of PfSPZ. Before Sanaria begins work towards rearing only female larvae and adult *A. stephensi,* we needed to determine the capacity of virgin females to produce PfSPZ. We provided Pf-infected blood meals to 3-day old virgin and mated *A. stephensi* compared prevalence and intensity of Pf infections at the oocyst and PfSPZ stages. To verify that mosquitoes were either mated or unmated, spermathecae of at least ten mosquitoes from each group were dissected and scored visually for the presence or absence of sperm in the spermathecae. In 3 independent experiments, virgin mosquitoes had a mean intensity of 101 oocysts per mosquito (range 67-129) and prevalence of 99% (range 97-100), while mated mosquitoes had a mean intensity of 79 oocysts per mosquito (range 45-121) and prevalence of 93% (86 -100). The PfSPZ infection intensities were 275,661 PfSPZ/mosquito and 262,786 PfSPZ/mosquito for virgin and mated mosquitoes, respectively. These results unequivocally demonstrate that virgin and mated female *A. stephensi* are capable of producing comparable yields of PfSPZ. Further studies are in progress to compare the longevity of virgin and mated female mosquitoes. These characteristics are desirable for scaled up PfSPZ production under good manufacturing practice (GMP) conditions.

1150

WHOLE SPOROZOITE CULTURING SYSTEMS TOWARDS MANUFACTURING MALARIA VACCINES

Leslie Itsara[1], Yaxian Zhou[1], Julie Do[1], Samrita Dungel[1], Matthew Fishbaugher[2], Ashley Vaughan[2], Stefan Kappe[2], Anil K. Ghosh[1]

[1]MalarVx, Inc., Seattle, WA, United States, [2]Center for Infectious Disease Research, Seattle, WA, United States

Live sporozoite (SPZ) vaccines are the only vaccines that provide complete sterilizing protection against *Plasmodium* infection in mice and humans. A remaining hurdle for commercialization of whole SPZ vaccines is scalable manufacturing technology for SPZ production. To solve this problem, an *in vitro* culturing system to produce large quantities of SPZ has been developed. Minimal basal lamina components were determined for oocyst transformation and then five different oocyst medias (A-E) were tested for their ability to support oocyst/SPZ maturation over a twenty-five-day time course. Throughout the developmental studies, immunofluorescence assays (IFA) were performed using anti-PfCap380 to detect oocysts, anti-circumsporozoite protein (CSP), and DAPI to identify nuclear DNA. A separate ten-day oocyst time course was performed to study genome replication within *in vitro* oocysts to study endomitosis. SPZ were tested for gliding motility and hepatocyte invasion/traversal. Of the five oocyst medias (A-E), media C supported greatest oocyst growth and produced oocysts > 30 um, resembling mosquito-derived oocysts. On day 25, media C supported growth for the following numbers of oocysts in parentheses with a given diameter: 5 um (1895); 10 um (251); 15 um (107); 25 um (46); >30 um (34). Percentages of oocysts with a given number of

nuclear focus/*Foci* on Day 10 are as follows - single focus = 12%, 2 *Foci* = 12%, 4 *Foci* = 4%, 8 *Foci* = 72%. SPZ that developed from oocysts were identified in media C conditions by morphology and protein marker expression. In conclusion, the *in vitro* culturing system supports maturation of oocysts, which resemble mosquito-derived oocysts in size (> 30mm). Genome replication occurs within oocysts as nuclear *Foci* double over the time course. SPZ resemble mosquito-derived midgut SPZ and are thus developmentally immature compared to salivary gland SPZ. Current and future studies are focused on SPZ maturation by testing additional media and basal lamina components to mature SPZ for malaria vaccines.

1151

SAFETY, TOLERABILITY AND IMMUNOGENICITY OF PFSPZ VACCINE IN EQUATOGUINEAN CHILDREN AND OLDER ADULTS

Vicente Urbano[1], Ally Olotu[2], Ali Hamad[2], Mwajuma Chemba[2], Stephen R. Manock[3], Maximillian Mpina[2], Elizabeth Nyakarungu[2], Esther Eburi[4], Antonio Enrique Ngua Sama Roca[4], Martin Eka Ondo Mangue[1], Thomas Stabler[3], Yonas Abebe[3], Salomon Nguema Owono[1], Matilde Riloha Rivas[1], Christopher Schwabe[5], Julie Niemczura[5], Guillermo Garcia[5], Wonder Philip Phiri[4], Luis Segura[4], Tobias Schindler[6], Elizabeth Saverino[3], Peter F. Billingsley[3], B. Kim Lee Sim[3], Claudia Daubenberger[6], Thomas Richie[3], Salim Abdulla[2], Stephen L. Hoffman[3]

[1]Ministry of Health and Social Welfare, Malabo, Equatorial Guinea, [2]Ifakara Health Institute, Bagamoyo, United Republic of Tanzania, [3]Sanaria Inc, Rockville, MD, United States, [4]Medical Care Development International, Malabo, Equatorial Guinea, [5]Medical Care Development International, Silver Spring, MD, United States, [6]Swiss Tropical and Public Health Institute, Basel, Switzerland

PfSPZ Vaccine is a candidate pre-erythrocytic malaria vaccine composed of aseptic, purified, live (metabolically active), radiation-attenuated, cryopreserved *Plasmodium falciparum* (Pf) NF54 sporozoites (SPZ). In trials in the U.S. and Africa, PfSPZ Vaccine administered by direct venous inoculation (DVI) to young adults proved safe and well-tolerated, and provided durable protection against homologous and heterogenous populations of Pf for at least 24 to 33 weeks. PfSPZ Vaccine has undergone limited testing in children in Tanzania and an ongoing trial in Kenya, but has not previously been tested in older adults. Since the eventual goal is to use PfSPZ Vaccine in mass vaccination programs for malaria elimination in specified geographical areas, it is necessary to test the vaccine in all age groups. As part of a larger randomized, double blind placebo-controlled trial, we evaluated the safety, tolerability, and immunogenicity of PfSPZ Vaccine in 62 healthy malaria-exposed Equatoguinean children and older adults. We randomized 15 adults age 36-65 years to receive 3 doses of $2.7x10^6$ PfSPZ of PfSPZ Vaccine, and 16 children age 11-17 years, 16 children age 6-10 years, and 15 children age 1-5 years to receive 3 doses of $1.8x10^6$ PfSPZ, or placebo at 0, 8 and 16 weeks. A sentinel group of 3 subjects was vaccinated one day prior to the rest of each age cohort. Age de-escalation was done sequentially in children, with safety data evaluated by an external data and safety monitoring board before progressing to the youngest group. Adverse events (AEs) were solicited for 7 days and surveillance for unsolicited AEs done for 28 days after each vaccination. Monitoring for serious AEs was done throughout. Hematologic, renal and hepatic tests were done at baseline, 2 and 14 days after each vaccine dose. Blood samples for immunologic assays were taken prior to and 14 days after each vaccine dose, and at 4 and 20-24 weeks after the final vaccine dose. The vaccine was well-tolerated in all age groups, and DVI was generally straightforward with only mild pain associated with injection. Safety and immunogenicity data will be presented.

PfSPZ Vaccine is a candidate pre-erythrocytic malaria vaccine composed of radiation-attenuated, aseptic, purified, cryopreserved *Plasmodium falciparum* (Pf) NF54 sporozoites (SPZ). In trials in the U.S. and Africa, PfSPZ Vaccine administered by direct venous inoculation (DVI) provided durable protection against heterologous strains and heterogeneous populations of Pf for at least 24 to 33 wks. A second PfSPZ-based vaccine approach - administration of low doses of non-irradiated, infectious NF54 PfSPZ (PfSPZ Challenge) under chloroquine chemoprophylaxis (PfSPZ-CVac) - protected against homologous strains of Pf in the U.S. and Europe for at least 10 wks, but had not been tested in Africa. We conducted a randomized, double blind placebo-controlled trial comparing tolerability, safety, immunogenicity and efficacy against controlled human malaria infection (CHMI) of PfSPZ Vaccine versus PfSPZ-CVac in healthy malaria-exposed Equatoguinean 18 to 35-year-old men and women. We randomized 26 subjects to receive 3 doses of $2.7x10^6$ PfSPZ (PfSPZ Vaccine) or placebo at 0, 8 and 16 wks, and 24 subjects to receive 3 doses of $1x10^5$ PfSPZ (PfSPZ Challenge) or placebo at 0, 4 and 8 wks after an oral dose of chloroquine (CQ) 600 mg base then CQ 300 mg base weekly (PfSPZ-CVac), followed in both groups by homologous CHMI at 10-13 wks post final vaccine dose. Adverse events (AEs) were solicited for 7 days and surveillance for unsolicited AEs done for 28 days after each vaccination. Monitoring for serious AEs was done throughout. Hematologic, renal and hepatic tests were done at baseline, 2 and 14 days after each vaccination, and prior to CHMI. Blood samples for humoral and cellular immunology were taken at baseline and 14 days after each vaccination. Both vaccine approaches were well-tolerated, and DVI was typically straightforward with only mild pain associated with injection. Safety, immunogenicity and efficacy data will be presented. This comparison of PfSPZ Vaccine and PfSPZ-CVac will provide more information as to which product could be used in mass vaccination programs aimed at regional elimination of malaria.

1153

PROTECTIVE EFFICACY OF CONDENSED PFSPZ VACCINE IMMUNIZATION REGIMENS AGAINST HETEROLOGOUS CONTROLLED HUMAN MALARIA INFECTION

Benjamin Mordmüller[1], Zita Sulyok[1], Albert Lalremruata[1], Johanna Weirich[1], Zsófia Molnár[1], Antje Theurer[1], Carlos Lamsfus Calle[1], Meral Esen[1], Mihály Sulyok[1], Thomas L. Richie[2], B. Kim Lee Sim[2], Stephen L. Hoffman[2], Peter G. Kremsner[1]

[1]University of Tuebingen, Tuebingen, Germany, [2]Sanaria Inc., Rockville, MD, United States

Optimized regimens for immunization with *Plasmodium falciparum* (Pf) sporozoites (SPZ) have >75% protective efficacy against homologous and heterologous Pf. Thus, they are the only approach meeting WHO's preferred product characteristics. PfSPZ Vaccine consists of radiation-attenuated PfSPZ to translate whole cell vaccination to prevent malaria into a pharmaceutical product. PfSPZ Vaccine clinical development in malaria-naïve adults has focused on dose optimization and protection against homologous controlled human malaria infection (CHMI). Exploratory studies indicate that heterologous, long-lasting protection can be achieved. We systematically investigated if the current 16-week, 3-dose immunization regimen can be condensed into a maximum of 28 days and assessed vaccine efficacy (VE) by cross-over CHMI using homologous (NF54) and heterologous (7G8) PfSPZ (MAVACHE, ClinicalTrials.gov NCT02704533). In the first part of the trial, vaccination on Days 0, 7 and 28 with $0.9x10^6$ PfSPZ protected 5/5 volunteers against homologous CHMI, whereas vaccination on Days 0 and 7 with $1.35x10^6$ or $2.7x10^6$ PfSPZ was less efficacious (4/6 and 3/6 protected, respectively). To verify VE of the Day 0, 7, 28 regimen, 18 volunteers were allocated to placebo (n=6) or PfSPZ Vaccine (n=12) and underwent repeat CHMI by direct venous inoculation of 3,200 PfSPZ of PfSPZ Challenge (NF54) and PfSPZ Challenge (7G8), pharmaceutical products for standardized CHMI. PfSPZ for CHMI were administered sequentially (NF54-7G8 or 7G8-NF54) 3 and 8 weeks following last vaccination and the endpoint was asexual blood stage parasitemia. Allocation ratio to either sequence was 1:1, nested in the placebo and PfSPZ Vaccine arms. Immunization and CHMI were safe and well tolerated. No serious adverse event occurred. Following first CHMI, 9/18 volunteers developed malaria (3/12 immunized with PfSPZ Vaccine). The second CHMI is ongoing with currently 4/10 volunteers parasitemic (1/7 immunized with PfSPZ Vaccine). The study will be unblinded in July 2018. Final results including immunological investigations will be presented.

1154

CAN DURABILITY OF LONG-LASTING INSECTICIDAL NETS BE PREDICTED FROM A 'RISK INDEX' COMPOSED OF SELECTED VARIABLES ON NET HANDLING AND USE ENVIRONMENT?

Albert Kilian[1], Hannah Koenker[2]

[1]U.S. Agency for International Development Vectorworks Project, Tropical Health LLP, Montagut, Spain, [2]U.S. Agency for International Development Vectorworks Project, Johns Hopkins University Center for Communication Programs, Baltimore, MD, United States

Recent studies on the physical durability of LLIN have shown that the outcomes - measured as median survival of the nets in serviceable condition - can vary significantly for the same LLIN brand between locations with different net use environments and net care and repair behaviors. This suggests that these factors would be more predictive of durability than the textile-based quality differences between brands. To provide proof of principle a net durability "Risk Index" (RI) was constructed using data from ongoing LLIN monitoring by the VectorWorks project from 12 sites in five countries. The RI was constructed from three composite groups of household or net-based variables. *Net handling* (45% of total score) had five variables: ever storing food in sleeping room, ever cooking in sleeping room, leaving net hanging during the day, drying net on fence or bush, and washing with detergent or bleach; *Net use environment* (10%) with four variables: dwelling walls, rodents in vicinity, firewood as cooking fuel and type of sleeping place; *Behavior and Attitudes* (45%) with three variables: recall of message "care for your net" and "repair net" and composite care and repair attitude score. Weights for each variable were given based on hypothetical importance to result in a maximum RI value of 100. At baseline RI scores at the 12 sites varied between 27 and 72 with a median of 57 and inter-quartile range of 50 to 64. Median survival estimates at 24 months of follow up is currently available for five sites while the other sites will collect this data before September 2018. Median survival varied between 2.7 and 5.6 years and in a regression analysis the baseline RI score was significantly associated with the outcome ($p=0.005$, $R^2=0.93$) suggesting that each 10-point increase of the RI results in a 0.6 year decrease in median LLIN survival. While this data shows that in principle a "Risk Index" is able to predict the survival outcome, more work is needed to optimize the RI construction and then validate the RI using independent data.

1155

SUPPRESSING *PLASMODIUM* INFECTION AND MIDGUT MICROBIOTA OF *ANOPHELES* USING A TRANSGENIC CONDITIONAL SPONGE MICRORNA APPROACH

Shengzhang Dong[1], Yuemei Dong[1], Maria L. Simoes[1], Xiaonan Fu[2], Jinsong Zhu[2], George Dimopoulos[1]

[1]Johns Hopkins University, Baltimore, MD, United States, [2]Virginia Polytechnic Institute and State University, Blacksburg, VA, United States

MicroRNAs (miRNA) are small endogenous noncoding RNAs that bind to specific miRNA recognition elements of target RNAs, and have been shown to play a central role in the regulation of gene expression, primarily via RNA decay or translational inhibition. miRNAs have been extensively studied in several diseases transmitting mosquitoes vectors, including the yellow fever mosquitoes *Aedes aegytpi* and the human malaria misquotes *Anopheles gambiae*. Most of these studies were concentrated on identification and annotation of miRNAs using high throughput sequencing and subsequent bioinformatics analysis. However, only a few miRNAs have been functionally studied in *Anopheles* mosquitoes. This is partly due to a paucity of genome-wide resources for assessing miRNA loss of function. Recently, miRNA sponges (SPs) were successfully used to define miRNA functions in multiple species and biological contexts. miRNA SP contains multiple or 'bulged', tandem binding target sites to a microRNA of interest. When SP is integrated to the genome of species using transgenic technique, it is regulated by acquired promoters and sequester target miRNAs, blocking the functions of target miRNA, and thus creating a knockdown of miRNA activities or a miRNA null mutant. We have used a transgenic approach to target two miRNAs, aag-miR-14 and aag-miR-305, through conditional expression of miRNA SPs to investigate their implication in regulating *Plasmodium falciparum* infection and the midgut microbiota. We will discuss four transgenic lines expressing these two miRNAs SPs, under the control of the blood-inducible tissue-specific *carboxypeptidase* (*Cp*), or *vitellogenin* (*Vg*), promoters. Expression of selected SPs significantly reduce the amount of endogenous target miRNAs in midguts or fat bodies of females after ingesting a blood meal, resulting in suppressing parasite oocyst loads and microbiota loads in midguts without obvious fitness costs. Ongoing studies will explore potential target genes that are regulated by each miRNA, and may represent anti-parasitic and antibacterial effectors.

1156

DETERMINING SPECIES OF FIELD-COLLECTED MOSQUITOES USING NEAR-INFRARED SPECTROSCOPY

Pedro M. Esperança[1], Dari F. Da[2], Bernard M. Somé[2], Maggy T. Sikulu-Lord[3], R. Serge Yerbanga[2], Thierry Lefèvre[2], Karine Mouline[2], Karidia Wermé[2], Floyd E. Dowell[4], Roch K. Dabiré[2], Thomas S. Churcher[1]

Tracking changes in vector populations—such as species abundance, age distribution and infection—constitutes a direct measure of the efficacy of vector control interventions. Near- infrared spectroscopy (NIRS) is a rapid and non-destructive scanning technique that has been shown to differentiate morphologically identical *Anopheles gambiae* and *An. arabiensis* sibling species. In this study, we evaluate the potential of NIRS to determine the species of laboratory-reared mosquitoes using machine learning (ML) models calibrated using colony mosquitoes. Mosquitoes of different species (*Anopheles arabiensis*, *Anopheles coluzzii*, *Anopheles gambiae*) were collected in three different field locations in Burkina Faso and reared to adulthood under laboratory conditions alongside colony mosquitoes. Following emergence, colony mosquitoes were killed and scanned daily using NIRS. Maternal generation (F0) and offspring generation (F1) reared from field collected mosquitoes were killed and scanned 4 days post-emergence and the species determined by PCR. Multinomial generalised linear models were constructed and cross-validated to predict mosquito species from their spectra. NIRS was able to differentiate the three species of colony mosquitoes of constant age, including the previously untested *An. coluzzii*, with misclassification rates below 7% in all cases. Species could also be determined in colony mosquitoes where the age of the mosquito varied and was unknown though the accuracy was lower. Colony mosquitoes could predict the species of laboratory reared F0 and F1 mosquitoes with some loss of accuracy depending in species, location and generation. The work indicates that NIRS is able to identify the three most epidemiologically important species in the *Anopheles gambiae* complex with relatively high accuracy. The precision of the method diminishes with the increased realism investigated here (location of the population, age of mosquito) though NIRS still appears to a promising tool for mosquito surveillance that needs to be further validated in the field.

1157

INSECTICIDE SUSCEPTIBILITY STATUS OF *ANOPHELES GAMBIAE* S.L TO PUBLIC HEALTH INSECTICIDES FROM TWELVE SENTINEL SITES IN UGANDA

Michael Okia[1], David Hoel[2], James Kirunda[1], Betty Mpeka[1], Muhanguzi Asaph[1], Richard Ocan-. Onen[1], Opigo Jimmy[3], Katamba Vincent[3], Richard Echodu[4], Ananya Price[5]

Increasing insecticide resistance is a threat to vector control interventions in Uganda. This monitoring investigated possible changes in the resistance status of local vectors to insecticides used for indoor residual spraying (IRS) and on long-lasting insecticidal nets (LLINs) in twelve different sites (districts) in Uganda. Susceptibility levels in *Anopheles gambiae* s.l. to DDT, three pyrethroid, two organophosphate and one carbamate insecticide collected from twelve sentinel surveillance sites across Uganda in 2016 and 2017 were determined using the standard WHO insecticide susceptibility test kit. Clothianidin and chlorfenapyr were tested in one and two sites, respectively. Our results show that *Anopheles gambiae* s.l. were susceptible (99-100% mortality) to pirimiphos-methyl in all study sites, but malathion had a reduced mortality of 89.4% in Soroti. Mortality to carbamates varied between 88% in Arua and 100% in all other study districts tested. Mosquitoes were susceptible to DDT in Apac and Tororo Districts (98-100% mortality), with suspected resistance in Bugiri, Lira and Soroti Districts (90.8-92% mortality), and resistance in Arua, Gulu and Kanungu Districts (15-26% mortality). Resistance to pyrethroids was observed in most sites, except for suspected resistance to deltamethrin (91% mortality) and to permethrin (91% mortality) observed in Lira District in 2017. Mortality to clothianidin in Tororo was 96.6% at 7 days post-exposure, while mortality to chlorfenapyr in Soroti and Tororo was 99.7% and 100% respectively at three days post-exposure. We noted reduced susceptibility to carbamates in Arua, Lira, Kanungu and Tororo Districts, indicating the need for continued annual monitoring for insecticide resistance. Both East (L1014S) and West African (L1014F) *kdr* mutations were present in *An. gambiae* and *An. arabiensis*. Widespread resistance to all IRS insecticides except pirimiphos-methyl, currently used in IRS, imparts urgency for testing new compounds such as clothianidin and chlorfenapyr to manage insecticide resistance through rotation with different modes of action.

1158

COMMUNITY-BASED LLIN DISTRIBUTION: DESIGN AND IMPLEMENTATION LESSONS FROM ZANZIBAR

Waziri Nyoni[1], Noela Kisoka[1], Jacqueline Madundo[2], Mwinyi Khamis[3], Abdullah Ali[3], George Greer[4], Naomi Kaspar[4], Ato Selby[1], Eric Filemyr[1], Hannah Koenker[1], Matt Lynch[1]

[1]U.S. Agency for International Development VectorWorks Project, Johns Hopkins University Center for Communication Programs, Baltimore, MD, United States, [2]National Malaria Control Programme, Ministry of Health, Dar es Salaam, United Republic of Tanzania, [3]Zanzibar Malaria Elimination Programme, Zanzibar, United Republic of Tanzania, [4]US President's Malaria Initiative, US Agency for International Development, Dar es Salaam, United Republic of Tanzania

In 2014 Zanzibar adopted continuous distribution (CD) of long-lasting insecticidal nets (LLINs) to maintain high levels of ITN ownership and access. Shehas (heads of the ward) issue coupons to qualifying heads of household, who then redeem them for nets at nearby health facilities. The CD channels are run and managed by the Zanzibar Malaria Elimination Program (ZAMEP) and 289,661 ITNs were delivered through community and ANC/EPI channels in 2014-2016. In collaboration with ZAMEP, VectorWorks led the redesign of the community channel in 2017, with the following objectives: 1) improve coupon security, 2) integrate coupon in the health commodities supply chain, 3) integrate coupons and LLINs issued in the Health Management Information System (HMIS), and 4) develop an automated and transparent coupon tracking system. To date, the community channel has been integrated into the health facility-based documentation process where information about coupons and LLIN recipients is captured in outpatient registers. Storage and delivery of coupons to health facilities has been integrated by Zanzibar Central Medical Stores (CMS), with management and delivery of coupons recorded with other health commodities. In order to improve coupon security, a number of steps have been taken. First, security features such as barcodes, holograms and unique numbers have been added to the coupons, to allow health facility staff to visually assess validity of coupons. Second, a coupon numbering system allows CMS to assign batches to specific Shehas, to easily track fraud by respective Shehas. Third, a coupon management system with a dashboard was developed within DHIS2. The coupon management system will be used by CMS to capture baseline information for all coupons received from suppliers, and track validity of redeemed coupons. Redeemed coupons will be sent to CMS with monthly HMIS reports from health facilities. The presentation will report on the

operational issues encountered during the implementation process, how the community channel and coupon management system works, and other programmatic lessons.

1159

ENTOMOLOGICAL INVESTIGATION OF *ANOPHELES* MOSQUITOES IN FOREST-RELATED AREAS IN ACEH, INDONESIA

Iqbal Elyazar[1], Farah Coutrier[2], Saptoro Rusmiarto[2], Dwiko Susapto[2], Abdul Fatah[3], Maria E. Sumiwi[4], Ferdinand D. Laihad[4], Elvieda Sariwati[5], Chris Cotter[6], Jennifer L. Smith[6], Adam Bennett[6]

[1]Eijkman-Oxford Clinical Research Unit, Jakarta, Indonesia, [2]Eijkman-Institute for Molecular Biology, Jakarta, Indonesia, [3]Aceh Provincial Health Office, Banda Aceh, Indonesia, [4]United Nations Children's Fund, Jakarta, Indonesia, [5]National Malaria Control Program, Ministry of Health, Jakarta, Indonesia, [6]Malaria Elimination Initiative, Global Health Group, University of California San Francisco, San Francisco, CA, United States

Plasmodium knowlesi infections have been identified in Aceh Province, Indonesia, and are known to be associated with forest-based work, such as logging, rubber-tapping, mining, and farming. *Anopheles cracens* and *An. latens* in the *Leucosphyrus* group have been demonstrated as vectors of *P. knowlesi* in Malaysia. However, there is a lack of evidence to support a role for these species as *P. knowlesi* malaria vectors in Aceh. Our study aimed to characterize the distribution, abundance, and behavior of potential *P. knowlesi* vectors in the districts of Aceh Besar and Aceh Jaya, Aceh Province, Indonesia. Entomological sampling was conducted every other month between April 2017 to April 2018 at three collection sites representative of three ecologies: forest site, forest-fringe site, and settlement site. For each ecological type, adult mosquitoes were collected using outdoor/indoor human-baited night collection, morning collection, light traps, and mosquito magnets; larval collection was conducted during habitat surveys. We morphologically identified vector species and analyzed resting and feeding habits, seasonal densities, longevity and the types of water bodies used as breeding sites. A total of 22,266 mosquitoes were collected, of which anophelines comprised 0.6% (1,408) and 99.4% (20,858) were non-anopheline. A total 31 *Anopheles* species were morphologically identified. Out of these anopheline mosquitoes, 55% (775/1.408), 23% (321/1.408) and 22% (312/1.408) were collected from the forest, forest-fringes and village settlement, respectively. Molecular analysis to identify species and examine for sporozoites is ongoing. These results will provide essential baseline data for understanding forest transmission and finding suitable and effective vector control strategies for high-risk forested malaria areas in Aceh.

1160

FACTORS ASSOCIATED WITH OWNERSHIP AND USE OF LONG-LASTING INSECTICIDAL NETS IN UGANDA: A CROSS-SECTIONAL SURVEY OF 48 DISTRICTS

Samuel Gonahasa[1], Catherine Maiteki-Sebuguzi[1], Grant Dorsey[2], Jimmy Opigo[3], Adoke Yeka[1], Amy Lynd[4], Janet Hemingway[4], Moses R. Kamya[1], Martin Donnelly[4], Sarah G. Staedke[5]

[1]Infectious Diseases Research Collaboration, Kampala, Uganda, [2]University of California, San Francisco (UCSF), San Francisco, CA, United States, [3]Ministry of Health (MOH/NMCP), Kampala, Uganda, [4]Liverpool School of Tropical Medicine (LSTM), Liverpool, United Kingdom, [5]London School of Hygiene & Tropical Medicine (LSHTM), London, United Kingdom

A cross-sectional community survey was conducted to assess ownership and use of long-lasting insecticidal nets (LLINs) in Uganda, approximately 3 years after the last universal coverage campaign (UCC) to distribute LLINs. The survey will serve as a baseline for an ongoing trial to evaluate the impact of LLINs distributed in Uganda's 2017-18 UCC, and included 104 clusters (health sub-district) across 5 administrative regions. Households were randomly selected using two-staged cluster sampling; 50 households were enrolled per cluster. Outcomes included household ownership of LLINs (at least one LLIN) and adequate LLIN coverage (at least one LLIN per 2 residents), and use of LLINs by residents (slept under a LLIN the previous night). In March-June 2017, 5200 households were enrolled, including 29,649 household residents, and 6,953 bed-nets. Overall, 65.0% of households owned at least one LLIN (down from 94% in 2014), ranging from 55.6% in the mid-north east to 72.4% in the south-west. In an adjusted analysis, the factors most strongly associated with LLIN ownership were living in wealthier households (highest tercile vs lowest; adjusted odds ratio [aOR] 1.94, 95% CI 1.66-2.28, p<0.001) and less time since the last UCC (29-37 vs 42-53 months; aOR 1.91, 95% CI 1.60-2.28, p<0.001). Only 17.9% of households were adequately covered by LLINs (down from 65% in 2014), ranging from 10.6% in the mid-north east to 25.4% in the south-west. The factors most strongly associated with adequate LLIN coverage were fewer household residents (2-4 vs >7; aOR 6.52, 95% CI 5.13-8.29, p<0.001), living in wealthier households (highest tercile vs lowest; aOR: 2,32, 95% CI 1.88-2.85, p<0.001) and less time since the last UCC (29-37 vs 42-53 months; aOR 2.13, 95% CI 1.61-2.81, p<0.001). Only 39.5% of residents reported using LLINs. Age was strongly associated with LLIN use (5-15 vs <5 years; aOR 0.58, 95% CI 0.55-0.62, p<0.001), as were household wealth and time since the last UCC. LLIN ownership and adequate coverage have reduced markedly in Uganda since the last UCC, vary by region, and are lowest in poorer households. Larger households and school-aged children are also at risk.

1161

OPTIMIZING ENDECTOCIDE USE TO MITIGATE RESISTANCE DEVELOPMENT AND IMPROVE MALARIA CONTROL SUSTAINABILITY

Hannah R. Meredith, Laith Yakob

London School of Hygiene & Tropical Medicine, London, United Kingdom

The most common methods of malaria vector control, long lasting insecticidal nets (LLINs) and indoor residual spraying (IRS), have significantly reduced the burden of malaria. However, several hurdles remain before elimination can be achieved: mosquitoes are increasingly reported to seek their blood meals outdoors; mosquitoes that are more generalist in their host choice can more easily avoid human contact while traditional control tools are at their most potent; and mosquitoes have developed multiple modes of resistance to the insecticides used in LLINs and IRS due to their widespread use. Endectocides, insecticides applied directly to blood-hosts to kill mosquitoes that take a blood meal, offer a promising solution that could improve current vector control methods. These chemicals can be deployed to target mosquitoes displaying a range of feeding behaviors. Although endectocides have been shown to effectively reduce malaria transmission for 1-3 weeks after being applied, they are currently only applied once or twice a year. Consequently, mosquito populations can recover between treatments and the transmission cycle of malaria is not broken. If long term vector control is to be accomplished, we need to increase the application frequency of endectocides while taking care not to promote resistance. Here, we describe a mathematical model that explores dosing regimens using endectocides for humans and livestock that effectively reduces malaria transmission long term while minimizing the selection for endectocide-resistant mosquitoes. We also describe scenarios whereby resistance to insecticides used in LLINs and IRS can be more effectively managed through co-deployment with endectocides.

1162

WIDESPREAD INSECTICIDE RESISTANCE REPORTED IN COUNTRIES WITH THE HIGHEST MALARIA BURDEN

Melinda P. Hadi[1], Duncan K. Athinya[1], Seline A. Omondi[2], Eric O. Ochomo[2], Helen Pates Jamet[3]

[1]Vestergaard, Nairobi, Kenya, [2]Kenya Medical Research Institute, Kisumu, Kenya, [3]Vestergaard, Washington, DC, United States

The decrease in malaria cases between the year 2000 and 2015 has largely been attributed to vector control using long lasting insecticidal

nets and indoor residual spraying. However, in 2016 the number of malaria cases worldwide increased compared to 2015. Insecticide resistance in malaria vectors is one of the challenges recognized by WHO for malaria elimination. The decreased ability of current vector control tools to effectively kill mosquitoes may be an early indicator to an increase in malaria cases and attributed deaths. Visualizing the confirmed reports of insecticide resistance in malaria endemic countries provides an indication where resistance may play a role in the persisting malaria burden. Launched in 2012, IR Mapper (www.irmapper.com) geospatially displays reports of insecticide resistance in malaria vectors. As of March 2018, the *Anopheles* IR Mapper platform consisted over 19,500 unique data points from 2,664 localities in 60 countries. 85% of the countries reported confirmed resistance to at least one of the four main insecticide classes for malaria vector control. According to the World Malaria Report, in 2016 only 15 countries accounted for 80% of all malaria cases globally. Confirmed resistance to pyrethroids was widely reported in all 15 countries. Confirmed resistance to carbamates was also reported in 14 of the 15 countries. Target site knockdown mutations (*kdr)* and overexpressed oxidase metabolic mechanisms were the main resistance mechanisms reported in these countries. IR Mapper is a useful tool for visualizing the spatiotemporal spread of insecticide resistance in *Anopheles* mosquitoes and can be used to assist in decision making for deployment of the most appropriate tools and development of insecticide resistance strategies.

1163

AN ENTOMOLOGICAL SURVEILLANCE PLANNING TOOL TO IMPROVE ENTOMOLOGICAL INTELLIGENCE FOR EVIDENCE-BASED VECTOR CONTROL DECISION-MAKING TOWARDS MALARIA ELIMINATION

Yasmin Alia Williams[1], Allison Tatarsky[1], Cara Smith Gueye[1], Elodie Vajda[1], Neil F. Lobo[2]

[1]University of California San Francisco, San Francisco, CA, United States, [2]University of Notre Dame, South Bend, IN, United States

To accelerate progress towards malaria elimination, the World Health Organization (WHO) Global Technical Strategy 2016-2030 calls for maximizing the impact of vector control by strengthening entomological surveillance and capacity and managing insecticide resistance and residual transmission. In response to these efforts, we have developed a draft Entomological Surveillance Planning Tool (ESPT) to distil WHO guidance into an operational, decision-support tool for national malaria programs to support cost-effective, locally tailored, evidence-based vector control. The ESPT aims to support countries in generating entomological intelligence that guides vector control intervention selection, deployment in time and space, and provides a platform to evaluate complementary strategies and tools. To this end, the ESPT consists of a series of decision trees to help guide countries in the collection of the priority entomological indicators needed to make decisions through: 1) baseline surveys, 2) routine sentinel surveys, 3) focus investigations, and 4) entomological surveys based on priority programmatic questions. These decision trees link to the priority minimum indicators, a trapping methodology matrix to guide collections, data collection forms, and guidance on selecting sites for entomological investigations. In collaboration with national malaria programs and local partners, pilots of the ESPT have begun in three countries. Parallel evaluation activities are underway and include: 1) qualitative assessments to measure the ESPT's feasibility, acceptability, utility, and impact on vector control program decision-making; 2) costing of entomological surveillance activities and the cost per indicator; and 3) tracking decision-making on vector control strategy as related to implementation of the ESPT. Preliminary data from the pilot evaluations will be available by mid-2018 and will inform future iterations of the ESPT for malaria programs.

1164

COSTS AND COST-EFFECTIVENESS OF ITN DISTRIBUTION STRATEGIES IN SUB-SAHARAN AFRICA

Sara Scates[1], Janna Wisniewski[1], Olivier Briet[2], Timothy Finn[1], Waziri Nyoni[3], Mwinyi Khamis[4], Renata Mandike[5], Ally Mohamed[5], Karen Kramer[2], George Greer[6], Naomi Kaspar[6], Sylvester Segbaya[3], Emmanuel Flagbey[3], Prince Owusu[3], Mavis Osafo[3], Alex Brown[7], Mamadou Sangare[7], Melanie Joiner[7], Jules Mihigo[8], Diakalia Koné[9], Angela Acosta[3], Hannah Koenker[3], Joshua Yukich[1]

Insecticide-treated nets (ITNs) are one of the most cost-effective measures for preventing malaria. WHO recommends both large-scale mass distribution campaigns (MC) and continuous distributions (CD) as part of a multifaceted strategy to achieve and sustain universal access to and coverage of ITNs. A combination of these strategies has been effective for scaling up net coverage. For policy makers to make informed decisions on how to efficiently implement CD strategies, information on the costs and cost effectiveness of these delivery systems is necessary. To address this gap in CD cost data, costs of four types of delivery systems (mass campaigns, routine health services (ANC and EPI), schools, and community distribution), were collected in various country contexts. Data on costs were collected retrospectively from financial and operational records, stakeholder interviews, and resource use surveys. Additionally, a systematic search of published cost literature was conducted. The OpenMalaria platform was used to develop simulations of the health effects of various ITN distribution scenarios and these results were combined with the systematic review results to make cost-effectiveness (CE) estimates for each scenario. Results from the case series and systematic review demonstrate that the average economic costs of CD systems per net (3.21 (USD) (95% CI 2.55-3.86)) were not significantly higher than the MCs reviewed (2.34 (USD) (95% CI 1.63-3.04)), despite a higher mean cost per ITN distributed. Results also showed that CD systems involve more country contributions than MCs per ITN. Incremental Cost Effectiveness Ratios (ICER) and CE expansion paths were estimated under varying transmission contexts and intervention deployment histories. ANC and EPI distribution alone is likely to be the most efficient (i.e. lowest cost per case of malaria averted) use of resources for ITN distribution and favored under the most resource limited situations. ANC/EPI had the lowest ICER compared to no vector control in more than 80% of simulated scenarios. Other CD systems can perform at similar levels of efficiency to repeated mass campaigns.

1165

POPULATION SEASONALITY AND RELEASE TIMING SIGNIFICANTLY AFFECT THE PROBABILITY OF ESTABLISHMENT FOR SMALL RELEASES OF GENE DRIVE MOSQUITOES

Milen Nikolov[1], Andre L. Ouédraogo[1], Andrea K. Beaghton[2], Pantelis J. Beaghton[2], Edward A. Wenger[1], Austin Burt[2], Philip A. Welkhoff[3]

[1]Institute for Disease Modeling, Bellevue, WA, United States, [2]Imperial College London, London, United Kingdom, [3]Bill & Melinda Gates Foundation, Seattle, WA, United States

Highly efficient CRISPR/Cas9 gene-drive systems have recently been developed, targeting reproductive-capacity and malaria-competency loci of malaria transmitting vector species, such as An. gambiae. The resulting drive systems aim to either suppress the local wild-type population or alter its genome, conveying desirable phenotypes such as *P. falciparum* refractoriness. The potential for sustained spread of gene drive constructs as proposed for malaria and a variety of other applications (pest control, tick borne diseases, dengue) has raised concerns for unintentional or unauthorized organism release outside approved and strictly-regulated trial sites. Previous analyses posit that as few as one or two gene drive organisms carrying efficient gene drive cassettes may establish a permanent (sub)population of genetically-modified (GM) mosquitoes with probability >50%. While these results are broad and cautionary, we show that seasonality is a fundamental environmental characteristic to consider when modeling decision variables. For the first time, we investigate the impact of gene-drive release timing and numbers on the establishment probability of GM vectors in the context of realistic seasonal population variation. We model a male sex bias, driving-Y population suppression gene drive, targeting An. gambiae, since these are among the first field trials candidate constructs. We analyze gene-drive establishment in geographies of different seasonality and spatial vector population features. We show that releasing a small number of gene-drive mosquitoes over the few weeks in the beginning of the wet season facilitates population founder effects and high establishment probability: between 60% - 80% for releases of as few as one or two mosquitoes. However, releasing gene-drive mosquitoes outside this time results in much lower establishment probability, typically <20%. Our findings address crucial ethical and environmental concerns, which may guide whether, how, and where to set up gene-drive trials.

1166

RESULTS FROM A COMPARISON-CONTROL TRIAL EXAMINING DIFFERENT TARGETING STRATEGIES FOR IRS ZAMBIA 2017

David A. Larsen[1], Anne C. Martin[2], Derek Pollard[2], Carrie F. Nielsen[3], Busiku Hamainza[4], Anna Winters[5]

[1]Syracuse University, Syracuse, NY, United States, [2]Akros Inc., Lusaka, Zambia, [3]Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention and US President's Malaria Initiative, Lusaka, Zambia, [4]National Malaria Elimination Center, Government of the Republic of Zambia, Lusaka, Zambia, [5]University of Montana, Missoula, MT, United States

Indoor residual spraying (IRS) is a powerful intervention in the fight against malaria, but high cost prohibits most national malaria programs from achieving universal coverage. Most countries rely primarily on universal coverage of insecticide-treated mosquito nets (ITN) for malaria control and target IRS campaigns to prioritized areas. Yet, information is scarce on how IRS should be delivered to maximize impact and prevent the most malaria with limited resources. In collaboration with the National Malaria Elimination Centre in Zambia we conducted a comparison-control trial in 2017 and 2018 to evaluate different prioritization strategies for IRS. Six districts were divided into three groups (2 districts per group), with each receiving a different IRS targeting methodology for IRS operations (pirimiphos-methyl) in 2017. Group A received a geographic concentration strategy wherein all structures within a geographic area were targeted for IRS. This method (blanket spraying) aims for heavy saturation of IRS without spatial gaps. Group B used health facility incidence data from the health management information system (HMIS) to estimate malaria burden in each area and prioritize houses according to incidence at the nearest facility. Group C used a strategy of ecological targeting to allocate IRS based on predicted probability of *Anopheles funestus* as developed by the Malaria Atlas Project. IRS was implemented in late 2017, and all data will be analyzed by July 2018. The primary outcome is the incidence of uncomplicated malaria measured through the HMIS which will be analyzed using a difference-in-differences approach. The entomological inoculation rate (EIR) of local primary vector species is being measured through five routine entomological collections in 150 houses across the different arms and will serve as a secondary outcome; it will be assessed using post-only comparison between trial arms and between sprayed and unsprayed areas. Analyses will be finalized by September 2018. This presentation will discuss the results of this study and its implications for future targeting methodologies in Zambia and other countries using IRS.

1167

SOCIO-BEHAVIORAL SURVEILLANCE ON OUTDOOR SLEEPING AND OTHER OUTDOOR NIGHTTIME BEHAVIORS IN NORTHERN BENIN FOR INDOOR RESIDUAL SPRAYING DECISION-MAKING

M. C. Akogbeto[1], L. K. N'tcha[1], R. Aïkpon[1], A. Salako[1], F. Dagnon[2], M.E. Patton[3], M. Kouletio[2], M. Humes[4], R. Beach[5]

[1]Centre de Recherche Entomologique de Cotonou, Cotonou, Benin, [2]U.S. President's Malaria Initiative (PMI), U.S. Agency for International Development, Cotonou, Benin, [3]Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, U.S. President's Malaria Initiative, Cotonou, Benin, [4]U.S. President's Malaria Initiative, U.S. Agency for International Development, Washington, DC, United States, [5]Entomology Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, and U.S. President's Malaria Initiative, Atlanta, GA, United States

Indoor Residual Spraying (IRS) and insecticide treated nets (ITNs) in Benin have resulted in drastic reductions in entomological parameters that have not been accompanied by similarly large reductions in epidemiological indicators. To identify household (HH) practices that may impact vector control strategies, we performed nighttime socio-behavioral surveillance in northern Benin during the Harmattan (cold) season in January 2018 in two regions where IRS was performed and one where IRS was withdrawn. We selected a convenience sample of 96 HH with at least five HH members (HHM), of whom one had to have sufficient educational background to monitor and record nighttime HHM behaviors and locations. Surveillance occurred every 30 minutes between 7PM to 7AM every other night for one week for three nights in total. We interviewed heads of HH on perceptions and use of vector control strategies. Proportions were calculated using the number of HHMs ever observed in a location. Among 576 HHM observed during 7–10 PM, 5.7% slept indoors under an ITN and were potentially protected from mosquitoes; >90% were not protected because they were doing outdoor (50.3%) or indoor (25.3%) activities or were away from the HH (18.5%). Between 10 PM–7 AM, nearly all (98.1%) HHMs slept indoors; only 44.2% used an ITN. Approximately 30.1% of HHMs used other mosquito prevention measures, including coils (30.5%), insecticide bombs (28.5%), and local herbs (38.9%); use did not differ significantly between IRS and non-IRS areas. HHs were noted to have large amounts of belongings and clothing hanging on walls that served as potential mosquito resting places other than IRS-treated walls. The impact of IRS and ITNs on malaria transmission were likely impacted by HHM behaviors, such as outdoor nighttime activities and lack of ITN use, identified in our surveillance. However, these behaviors may have been influenced by the relatively cool, dry weather at the time of sur veillance. To provide more

information on how HHM behaviors may impact vector control strategies at other times of the year, we will repeat the surveillance during the hot season (March 2018) and rainy season (July 2018).

1168

THE IMPACT OF MASS BED NET DISTRIBUTION ON VECTOR SPECIES AND MALARIA PREVALENCE IN KILWA AND KASHOBWE, HAUT-KATANGA PROVINCE, DEMOCRATIC REPUBLIC OF THE CONGO

Tamaki Kobayashi[1], Thierry Bobanga[2], Solange Umesumbu[3], Serena Schatz[1], Mary Gebhardt[1], Ilinca I. Ciubotariu[1], Jordan E. Hoffman[1], Christine M. Jones[1], Jennifer C. Stevenson[1], Douglas E. Norris[1], William J. Moss[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Université Protestante au Congo, Kinshasa, Democratic Republic of the Congo, [3]National Malaria Control Programme, Kinshasa, Democratic Republic of the Congo

A mass insecticide-treated net (ITN) distribution campaign took place in Haut-Katanga Province, Democratic Republic of the Congo, a high transmission setting with little prior history of vector control, during September and October 2016. To measure the impact of the ITN distribution, cross-sectional surveys were conducted in Kilwa and Kashobwe in Haut-Katanga Province before and after the ITN distribution, with two surveys conducted in the rainy season (February 2016 and 2017) and two surveys in the dry season (July 2016 and August 2017). The surveys consisted of administering a questionnaire, collecting blood for microscopy and molecular studies, and indoor mosquito collections. In total, 210 households were surveyed, and 1,742 participants were enrolled. Over 2,000 female anophelines were collected using CDC light traps and pyrethroid spray catches. Following the mass ITN distribution, there was a significant increase in reported ITN usage the night before the study visit (59% (95% CI: 53, 65) in July 2016 vs 92% (95% CI: 89, 94) in February 2017) and decline in parasite prevalence by microscopy (mean prevalence of dry season and rainy season: 32% (95% CI: 29, 35) in 2016 vs 18% (95% CI: 16, 21) in 2017). Both before and after the ITN distribution, children 5-15 years of age had the highest parasite prevalence and reported less ITN usage compared to younger children (< 5 years of age) and adults (> 25 years of age). The overall reported ITN usage declined in August 2017 to 88% and the decline was greatest for children 5-15 years of age. In Kilwa and Kashobwe, malaria vectors were abundant throughout the year, with *Anopheles gambiae* and *An. funestus* as the predominant vectors. Blood meal PCR revealed that both species were highly anthropophilic. Prior to the ITN distribution, *An. gambiae* was most prevalent during the rainy season whereas *An. funestus* was most prevalent during the dry season; however, *An. funestus* became the predominant vector following the rainy season in 2017. A mass ITN distribution in Haut-Katanga Province impacted both vector counts and parasite prevalence but additional interventions will be needed to further reduce transmission.

1169

INSECTICIDE-TREATED NET ACCESS AND USE IN LIBERIAN HOUSEHOLDS, 2016

D. Levi Hinneh[1], **Oliver J. Pratt**[1], Victor S. Koko[1], Eric Diboulo[2], Kaa B. Williams[3], Jessica M. Kafuko[3], Mamadou O. Diallo[4]

[1]National Malaria Control Program, Ministry of Health, Monrovia, Liberia, [2]MEASURE Evaluation, U.S. President Malaria Initiative U.S. Agency for International Development, Monrovia, Liberia, [3]U.S. President's Malaria Initiative, U.S. Agency for International Development (USAID), Monrovia, Liberia, [4]Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, and U.S. President's Malaria Initiative, Atlanta, GA, United States

In Liberia, a malaria endemic country, one objective of the Malaria National Strategic Plan 2016-2020 is to achieve universal access to long-lasting insecticide treated nets. From 2010 to 2015, about 4.5 million insecticide-treated nets (ITNs) were distributed to a 2016 population of 4.6 million, through both mass campaigns and antenatal clinic visits. The National Malaria Control Program conducts ongoing countrywide social and behavior change (SBC) efforts to promote access to and use of ITNs. During the 2016 Malaria Indicator Survey (MIS), a nationally representative sample of 4,218 households (HH) was randomly selected and visited to assess ITN ownership, access (one ITN per two people), and use. Almost all women (99%) have heard of malaria, and 90% of them cited mosquitoes as a cause of malaria; of those 88% cited sleeping under a net as a way to avoid malaria. The night before the survey, 21141 persons slept in these HH, with an average number of five people per household. The proportion of HH with at least one ITN was 61% (95% CI 58-65), with a mean of 1.2 ITNs per HH. Over 80% of ITNs were obtained from mass campaigns. Thirty-four percent of HH reported having disposed of an ITN during the 12 months preceding the survey, for 1421 disposed ITNs, with tearing (89%) being the main reason. Forty-two percent of HH members had access to an ITN and 39% of HH members slept under an ITN the night before the survey, indicating high use: access ratio (93%). Net utilization was higher in rural areas (43%) than in urban areas (37%, p-value <0.001). In households with at least one ITN, 66% of 3315 children and 70% of the 304 pregnant women slept under an ITN the night before the survey. The high use:access ratio may reflect a strong culture of net use fostered through SBC efforts. To address its main challenge of ITN access, Liberia is exploring strategies to intensify its ITN program efforts especially in difficult-to-reach households. These strategies include using data from the 2016 MIS to target the 2018 mass campaign distribution geographically, considering new continuous distribution channels through schools and communities, and promoting proper net care.

1170

MINIMAL GENETIC DIVERSITY AND SPATIAL CLUSTERING OF CHOLERA CASES IN THE KATHMANDU VALLEY: IMPLICATIONS FOR A RING-VACCINATION STRATEGY

Mellisa Roskosky, Mohammad Ali, Jyoti Acharya, Amanda Debes, Colin Stine, David Sack

Johns Hopkins University, Baltimore, MD, United States

A ring vaccination strategy targeting the population living around the case was found to be useful in eradicating smallpox and lately in controlling the Ebola outbreak in Guinea. However, such vaccination strategy has yet to be evaluated for its ability to stop the transmission of cholera. In mid-2016, a cholera outbreak occurred in Kathmandu Valley, Nepal. This study aims to determine if a reactive, ring vaccination strategy would have been useful in preventing cholera transmission during that outbreak. Data on cholera cases were collected as part of hospital-based surveillance for cholera in the Kathmandu Valley from June 30th to November 30th 2016. Cases were confirmed by bacterial culture and/or polymerase chain reaction testing and the genetic relatedness of positive samples was determined. Subsequent household visits were made to obtain GPS coordinates of the case households. Geographic clusters of cases were visually determined based on potential transmission patterns in space and time, and tested for clustering using Ripley's K and L functions. A total of 193 cholera cases were reported during the surveillance period. MLVA genotyping showed minimal genetic diversity, with only a single clonal complex. GPS coordinates were available for 69 case households. Six geographic clusters were identified, all of which showed significant clustering of cases. Approximately 85% of the cases within a cluster occurred more than seven days after the index case. The minimal diversity seen in the clinical samples combined with the shape of the epidemic curve seems to indicate a clonal outbreak consistent with a common source followed by secondary fecal-oral spread from person to person. Thus, it seems unlikely that there were multiple endemic environmental sources for *V. cholerae* in the Kathmandu Valley in 2016. Cholera cases during the outbreak were clustered in space, and the majority of cases

occurred over a week after the initial cases in the cluster, allowing for an opportunity to prevent transmission of the disease through use of the vaccine soon after the initial case was identified.

1171

BEYOND DRINKING WATER FOR CONTROL OF TYPHOID FEVER: NOVEL RISK FACTORS FROM A CASE-CONTROL ANALYSIS IN BLANTYRE, MALAWI

Jillian S. Gauld[1], Franziska Olgemoeller[2], Peter J. Diggle[3], **Nicholas A. Feasey**[4]

[1]Institute for Disease Modeling, Bellevue, WA, United States, [2]Malawi-Liverpool-Wellcome Trust Clinical Research Programme, Blantyre, Malawi, [3]Lancaster University, Lancaster, United Kingdom, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Typhoid fever, caused by the bacteria *Salmonella* Typhi, remains a significant cause of mortality in low and middle income settings. Though well described as being spread via the fecal-oral route, the most important reservoirs are unknown in most endemic settings. Queen Elizabeth Hospital (QECH) in Blantyre, Malawi, experienced a sharp increase in cases of typhoid fever starting in 2011, the majority of which were multi-drug resistant. A case-control study was initiated to evaluate potential risk factors for typhoid fever in children. Pediatric cases were ascertained from diagnoses from QECH, while controls were selected at an approximate 4:1 ratio, and matched with cases by geographic city district. Stepwise variable selection was utilized to narrow the large survey of potential risk factors to a final variable set for analysis. A logistic regression with geographic city district as a fixed effect was conducted using R statistical software. Results from the variable selection indicated that variables evaluating cooking and cleaning water sources were more informative than drinking water sources for predicting disease. Other than healthcare-seeking, which controls for case-ascertainment, individuals using river water for cooking and cleaning have the highest estimated odds (odds ratio (OR)=3.7, 95% confidence interval (CI)=1.4-9.5)of being a case. Other identified risk factors present a complex but cohesive picture of water usage in Blantyre, including protective effects of having soap in the household (OR=0.52, 95% CI=0.31-0.90) and increased odds for those living further from their primary water source (OR=1.39 per standard deviation increase in distance, 95% CI=1.03-1.89). The results from this study implicate cooking and cleaning with river water as a probable exposure pathway for *Salmonella* Typhi in Blantyre, Malawi, and provide guidance for both city-level control strategies and environmental sampling. These results highlight the importance of capturing multiple water-related exposure pathways, not only drinking water, for diseases that are able to survive and propagate on surfaces and food after contamination.

1172

HOW DO INFANTS ACQUIRE A DYSBIOTIC MICROBIOTA EVENTUALLY LEADING TO PEDIATRIC ENVIRONMENTAL ENTEROPATHY? THE MITICA STUDY: INPUTS FROM THE FIELD

Violeta Moya-Alvarez, Pascale Vonäsch, Philippe Sansonetti

Institut Pasteur, Paris, France

Undernutrition contributes to more than 40% of the global child mortality rate. In 2016 stunting affected 155 million children. Stunting entails long-term repercussions for the child, such as impaired growth, defective immune response, and neuro-cognitive consequences. Epidemiological studies emphasize that undernutrition cannot be ascribed solely to food insecurity and that early life environmental exposures play a major role in the pathogenesis of the disease. Indeed, growing evidence indicates that a syndrome called pediatric environmental enteropathy (PEE) undermines proper nutrition. PEE is a chronic low-grade inflammation of the small intestine in response to repeated exposure to a highly microbiologically contaminated environment, including small intestinal bacterial overgrowth (SIBO). This entails changes in the resident gut microbiota and intestinal atrophy, eventually leading to nutrient malabsorption, and deficient responses to live-oral vaccines. Estimates indicate that up to 75-100% of children living in areas with high prevalence of enteric infections suffer from PEE. Identifying how the infant acquires a pediatric environmental enteropathy and a dysbiotic gut microbiota, and how it affects child nutrition and development, are the crucial questions to elucidate the pathological pathways associated with malnutrition and design future intervention strategies. The MITICA study intends to describe the composition of the infant gut microbiota at birth and its evolution during the first 6 months of life, as well as the possible presence of PEE. Therefore, we analyze the presence of a maternal dysbiotic microbiota and maternal malnutrition at delivery; the influence of external sources of microbial pollution; and the infant's nutritional patterns (breast-milk composition, duration of breastfeeding, time of weaning and diet). We conduct a longitudinal case-control study nested in a cohort of 112 mother-infant pairs in the Central-African Republic: 56 cases (malnourished pregnant women) and 56 controls (non-malnourished pregnant women) and their offspring are followed from delivery until 6 months of age.

1173

SAFETY AND EFFICACY OF NITAZOXANIDE ON DIARRHEA: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Mohammad Rashidul Hashan[1], Khaled Mosaad Elhusseiny[2], Huu H. Le[3], Hien Tong Thi Thu[4], Thuan Minh Tieu[5], Soon Khai Low[6], Thai Le Ba Nghia[7], Mai Nhu Y[7], Peter S. Eid[8], Phuong H. Nguyen[4], Loc Quang Le[9], Mohammed N. Abed[10], Le Huu Nhat Minh[11], Kenji Hirayama[12], Nguyen Tien Huy[13]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Faculty of Medicine, Al-Azhar University, Cairo, Egypt, [3]Saigon General Hospital, Ho Chi Minh, Vietnam, [4]School of Medicine, Vietnam National University, Ho Chi Minh, Vietnam, [5]Faculty of Health Sciences, McMaster University, Hamilton, ON, Canada, [6]School of Medicine, Faculty of Health and Medical Sciences, Taylor's University, Selangor, Malaysia, [7]Faculty of Medicine, Vo Truong Toan University, Hau Giang, Vietnam, [8]Faculty of Medicine, Ain Shams University, Cairo, Egypt, [9]Faculty of Medicine, University of Medicine and Pharmacy at Ho Chi Minh City, Ho Chi Minh, Vietnam, [10]Institute of Medical Technology Baghdad, Baghdad, Iraq, [11]University of Medicine and Pharmacy at Ho Chi Minh City, Ho Chi Minh, Vietnam, [12]Department of Immunogenetics, Institute of Tropical Medicine (NEKKEN), Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan, [13]Department of Clinical Product Development, Institute of Tropical Medicine (NEKKEN), Leading Graduate School Program and Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan

Diarrheal diseases are marked as the fourth leading cause of mortality among under-five children and ninth among the population globally. Therapeutic interventions for diarrhea are still mostly limited to supportive management due to the variety of potential pathogens and different drug categories. Hence, we aimed to systematically review the evidences on the safety and efficacy of nitazoxanide for treating infectious diarrhea. We searched 12 databases, including PubMed, Scopus, and Embase. Data were extracted from included studies and pooled as risk ratio (RR). We conducted a meta-analysis for both direct and indirect comparisons of each pathogen using R studio and Comprehensive Meta-analysis software. The primary endpoint was the clinical response through the cessation of diarrhea. The secondary endpoints were the parasitological response and any reported adverse events. In *Cryptosporidiosis*, the overall estimate favored nitazoxanide in both clinical and parasitological responses in comparison with placebo (RR 1.892, 95% CI [1.297, 2.759]); (RR 2.297, 95% CI [1.520, 3.471]), respectively. Among patients with *Giardia intestinalis*, nitazoxanide in comparison with placebo, showed a 150% increase in the probability of diarrheal cessation (RR 2.50, 95% CI [1.12, 5.58]). In *Clostridium difficile* infection, the network meta-analysis

depicted the non-inferior clinical response effect of nitazoxanide to metronidazole at both 7 and 31 days after treatment (RR 1.09, 95% CI [0.91, 1.29]); (RR 1.21, 95% CI [0.87, 1.69]), respectively. Nitazoxanide enhanced rotavirus induced diarrheal symptoms resolution and shortened duration among hospitalized patients. We highlighted the effectiveness of nitazoxanide in cessation of diarrhea caused by *Cryptosporidiosis* and *Giardia intestinalis* infection. We also found the non-inferiority of nitazoxanide to metronidazole, so it might be beneficial in the treatment of *Clostridium difficile* infection. We recommend nitazoxanide as a good option for treating infectious diarrhea. Conducting further trials is highly suggested for other diarrheal conditions such as hepatic amoebiasis.

1174

GENERAL KNOWLEDGE ON CHOLERA IS HIGH, BUT SAFE WATER ACCESS STILL A RISK IN HAITI, EIGHT YEARS INTO PUBLIC HEALTH CAMPAIGN AGAINST CHOLERA

Elisabeth P. Tadiri[1], Ralph Ternier[2], J. Gregory Jerome[2], Molly F. Franke[3], Aaron Richterman[4], Yodeline Guillaume[1], Louise C. Ivers[1]

[1]Center for Global Health, Massachusetts General Hospital, Boston, MA, United States, [2]Zanmi Lasante / Partners in Health, Port-au-Prince, Haiti, [3]Department of Global Health and Social Medicine, Harvard Medical School, Boston, MA, United States, [4]Department of Medicine, Brigham and Women's Hospital, Boston, MA, United States

Eight years into a cholera epidemic in Haiti, despite a decrease in the rate of reported cases, transmission and cholera deaths continue. In the setting of comprehensive interventions including water, sanitation and hygiene (WASH) and oral cholera vaccination (OCV) campaigns, recent data on continued drivers of transmission is not available. We conducted a population-based survey of 1,868 households in Mirebalais, Haiti - a major hotspot for reported cholera cases - between March and November 2017. We assessed demographic and socioeconomic data, knowledge and self-reported practices related to cholera, and water quality (free chlorine residual) in the household water supply using a DPD (diethyl paraphenylene diamine) indicator test. In descriptive analyses, 1849/1868 (99%) respondents had heard of cholera. However, despite years of public health messaging, 103/1849 (6%) did not know how one gets cholera and 93/1,849 (5%) did not know any ways to avoid cholera. While 1417/1849 (76%) responded "washing hands" as a known method of avoiding cholera, only 229/1849 (12%) listed "not defecating near water source," and 70/1849 (4%) listed "vaccine." Although 982/1868 (53%) reported using household bleach, and 1293/1868 (69%) reported using Aquatabs (active ingredient is a chlorine donor) to treat water, only 305/1459 (21%) samples tested were within the recommended potable range of 0.2-2.0ppm. Of those who reported "sometimes" or "almost never" treating their drinking water, 360/669 (54%) cited a lack of necessary treatment products as the reason. In addition, 956/1868 (51%) households reported that water from their usual source was unavailable for at least 1 day in the past month. These findings suggest that broad national messages for cholera prevention have been well-received, but more targeted interventions may be needed at this stage to reach those low-knowledge subgroups. Further analysis of these data will provide guidance on specific target groups for interventions. Inconsistent access to safe water sources and the tools of water treatment are likely drivers of sustained transmission despite generally high knowledge.

1175

DETECTION AND CORRECTION OF HYPOKALEMIA IN A MALNOURISHED PEDIATRIC POPULATION WITH DIARRHEA IN RURAL NIGER

Antoine Maillard[1], Ali Moulaye[1], Sayadi Sani[2], Wendwaoga H. Ilboudo[1], **Susan Shepherd**[1]

[1]Alliance for International Medical Action, Dakar, Senegal, [2]Alliance for International Medical Action, Niamey, Niger

Serum electrolytes are commonly used to manage critically ill children, but this diagnostic is rarely available in pediatric humanitarian projects. Nonetheless, electrolyte disorders are significant in these contexts, in particular in malnourished children, where hypokalemia (serum [K+] <3.5 mmol/L) is frequent and associated with mortality risk. We document the prevalence of hypokalemia at admission and during hospitalization, and pilot the efficacy and tolerance of parenteral potassium (K+) correction in a malnourished population. Ill children (gastroenteritis or malaria) over 3 kg with MUAC ≥115 mm underwent point-of-care electrolyte testing. Those with capillary refill time ≥ 3 second or nutritional edema were excluded. Serum electrolytes were performed at admission and regularly until serum [K+] > 2.5 mmol/L. Intravenous K+ correction was carried out (0.6 or 1.0 mmol/kg over 3 hours) if serum [K^+] < 2.5 mmol/L. To date 51 children, 12 girls and 39 boys, among which 33 cases MUAC 115-124 mm, have been tested. 16 children have received parenteral K+ correction. 39 children (76 %) had hypokalemia, 22 of them severe (< 2.5 mmol/L) and 16 critical (< 2.0 mmol/L). Critical hypokalemia was more prevalent in children with MUAC 115-124 mm, non-significant trend, p = 0.17 No improvement was noted between the first and second K+ levels in 29 children receiving potassium-containing therapeutic milk (> 4 mmol K+/Kg/d). One third of all children tested (6/18 MUAC ≥ 125 mm, 10/33 MUAC 115-124 mm) received a K+ infusion without adverse event and with improvement in serum [K+] Hypokalemia is important in malnourished children in Niger: often severe and slow to correct with therapeutic milk suggesting a need to review the amount of K+ provided in the current formulation. Hypokalemia also appears to be common in pediatric patients, yet they do not benefit from K+ containing supplements, suggesting it is important to further describe electrolyte imbalances in hospitalized children in humanitarian settings and review K+ levels provided in intake. It remains to be determined whether correction of hypokalemia could improve the survival of these children.

1176

DISTINCT PROFILES OF ANTIMICROBIAL SUSCEPTIBILITY AND *SALMONELLA* SEROTYPES IN STOOLS OF CHILDREN ENROLLED IN THE GLOBAL ENTERIC MULTICENTER STUDY, 2007-2011

Irene N. Kasumba, Sunil Sen, Anna Roose, Jasnehta Permala-Booth, Sharon M. Tennant, GEMS Consortium

University of Maryland, School of Medicine, Baltimore, MD, United States

The Global Enteric Multicenter Study (GEMS) determined the etiological agents of moderate-to-severe diarrhea (MSD) in children under the age of five years living in Africa and Asia. *Salmonella spp.* were associated with MSD in children from Kenya and Bangladesh. Here, we describe the serovars and antimicrobial susceptibilities of *Salmonella spp*. from GEMS stools. *Salmonella* isolates were identified by GEMS sites using clinical microbiological methods. We subsequently serotyped the isolates by agglutination with O and H antisera. Specimens came from both children with diarrhea and healthy controls. We evaluated antimicrobial susceptibility using the Kirby- Bauer disk diffusion method. We determined *S*. Typhimurium sequence types using multi-locus sequence typing and/or whole genome sequencing. We isolated *Salmonella* spp. from 370 children. Of these, 188 were from Asia and 182 were from Africa. *S*. Typhimurium (22.7%), *S*. Paratyphi B Java (11.4%), *S*. Enteritidis (5.1%), *S*. Hissar (2.4%), and *S*. Typhi (2.2%) were the most abundant serovars in

stools of MSD cases. *S*. Virchow (9.7%), *S*. Newport (8.6%), *S*. Heidelberg (3.0%) were the most abundant serovars in stools of MSD controls. 2-3% of MSD episodes among Kenyan 0-23 month olds were attributable to *S*. Typhimurium, while 3.7% of MSD episodes in Kenyan 24-59 month olds and 1.9% of MSD episodes in Bangladeshi 0-11 month olds were attributable to serogroup B isolates. 1.2% of MSD episodes in Pakistani 0-11 month olds were attributable to serogroup D isolates, and 1.2% of MSD episodes in Bangladeshi 23-59 month olds were attributable to serogroup C1 isolates. Multidrug resistant *S*. Typhimurium and *S*. Enteritidis were isolated in Kenya and multidrug resistant *S*. Typhi was isolated in India. *S*. Typhimurium sequence type 313 was the predominant genotype from Kenyan stools. *Salmonella* isolated in GEMS show regional differences in serotype distribution as well as antimicrobial susceptibility. *S*. Typhimurium ST313, a dominant strain from invasive NTS in Africa, was the predominant strain in GEMS stools from Kenya.

1177

CALIBRATING A RABBIT COLONIZATION MODEL TO TEST A CANDIDATE MULTI-EPITOPE FUSION ANTIGEN (MEFA) VACCINE FOR ENTEROTOXIGENIC *E. COLI*

Richard M. Jones[1], Weiping Zhang[2], David Sack[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Kansas State University, Manhattan, KS, United States

Enterotoxigenic *E. coli* (ETEC) is a leading cause of children's diarrhea and travelers' diarrhea across the globe. Adopting a multi-epitope fusion antigen (MEFA) approach, a candidate vaccine was generated using epitopes from characteristic colonization factor antigens associated with ETEC infection. Previous work has shown that this fusion antigen, combined with administration of a toxoid fusion, induced broadly neutralizing antibodies in mice and protected STa+ or LT+ ETEC diarrhea in a pig model. Protection against ETEC colonization was not quantified in these studies, but is known to be a crucial step for the establishment of disease in humans. Earlier studies utilized a rabbit model to investigate the colonization of *Shigellae, Vibrio cholerae* and *E. coli* in the rabbit small intestine. We have adapted these methods for use with ETEC strains. After a 24 h fast, we challenged New Zealand white rabbits with 10^9, 10^{10}, or 10^{11} colony forming units of ETEC using oral gavage; this was combined with administration of sodium bicarbonate buffer and famotidine. After 24 h animals were sacrificed, and 10 cm intestinal sections were taken from the proximal and distal small intestine. These were opened, vortexed in sterile PBS, and dilution-plated on MacConkey agar for colony-forming units. Colonization was found to be limited to the distal small intestine. Strain H10407 (a strain producing CFA/1 and LT/ST) showed an attenuated initial colonization when compared to strain B7A (a strain producing CS6 and LT/ST). Additionally, serum collected from immunized rabbits shows a multiple fold-change response in IgG antibody titers directed towards each of the colonization factor antigens in the fusion antigen. By combining direct colony counts with serology, we have developed a robust model to investigate the candidate MEFA vaccine and future candidate vaccines for ETEC.

1178

THE SYMPTOMS CHARACTERISTICS OF INFECTIOUS DIARRHEAL WHICH CAUSED BY DIVERSIFORM PATHOGENS

Xin Wang, Huaiqi Jing

National Institute for Communicable Disease Control and Prevention, China CDC, Beijing, China

38950 cases of acute diarrheal who were from 0-99 years old were collected in the hospitals among 18 provinces of China during January 2010 to December 2016. The feces sample of each cases was detected 5 virus and 17 bacteria. We compared the symptoms which caused by different pathogens by statistical methods. It was found that the symptoms of infectious diarrheal caused by rotavirus and norovirus were showed obvious watery feces (OR=1.87 and 1.47 respectively, P<0.05) with vomit (OR=3.46 and 1.88 respectively, P<0.05) while stool routine test was negative. The symptoms of *Vibrio* spp. infectious diarrheal were similar with rotavirus and norovirus infection but leukocyte (OR=2.10, P<0.05) and erythrocyte (OR=2.42, P<0.05) were present in feces. The symptoms of *Salmonella*, EIEC, *Shigella* and *Campylobacter jejuni* infectious diarrheal were similar that showed fever (OR=2.47, 1.91, 3.21 and 1.98 respectively), mucus feces with blood (OR=2.21, 1.75, 18.55 and 6.98 respectively, P<0.05), feces leukocyte (OR=2.57, 2.42, 8.07 and 9.78 respectively, P<0.05) and erythrocyte (OR=2.85, 1.89, 17.10 and 9.04 respectively, P<0.05) positive. The symptoms *Yersinia enterocolitic*a were mild but leukocyte (OR=3.32, P<0.05) were present in feces obviously. And it may led quite a bit of *Y. enterocolitica* infections didn't go to see a doctor. It was very difficult to distinguish which pathogen cause the infectious diarrheal just according to the symptoms. But the symptoms characteristics could provide clues to the laboratory detection.

1179

UNEXPECTED LOW PREVALENCE OF TYPHOID AMONG ACUTE FEBRILE ILLNESS CASES IN INDIA

Govindakarnavar Arunkumar[1], **Jazeel Abdulmajeed**[1], Prathiksha P[1], Vallab Ganesh[1], Santhosha Devadiga[1], Sudheesh Nair[1], Anup Jayaram[1], Robin S[1], Aswathyraj Sushama[1], Prasad Varamballi[1], Anjali Aithal[1], Jagdish Prasad[2], Kayla F. Laserson[3]

[1]Manipal Academy of Higher Education, Manipal, India, [2]Directorate General of Health Services, MOHFW, New Delhi, India, [3]U.S. Centers for Disease Control and Prevention, India Office, New Delhi, India

Globally, an estimated 11-20 million people have typhoid fever and 150,000 die from it annually. In 2014, as part of Global Health Security, we initiated a facility-based acute febrile illness (AFI) surveillance platform to identify the etiologies of AFI in India. We defined AFI patients as patients with documented or reported fever <15 days duration; we enrolled all admitted AFI patients from 32 district/sub-district hospitals in 10 states of India. We recorded demographic and clinical data; we collected blood and tested for bacterial, viral and parasitic diseases. A positive BacT/ALERT blood culture was diagnostic of typhoid. Antibiotic susceptibility of Salmonella isolates were tested using vitek 2. We enrolled 27,431 AFI patients from June 2014-July 2017; of these, 14,134 (51.5%) were positive for any pathogen. The major etiologies were influenza (16.6%), dengue (9.7%), scrub typhus (8.6%), leptospirosis (8.1%), malaria (4.7%), KFD (2.2%) and typhoid (0.7%). Among the 200 typhoid cases, 156 were positive for *S.typhi*; and 44 cases were positive for *S.paratyphi A*. The percentage positivity of typhoid among AFI cases varied from 0.2-3.1 by state and was highest in Maharashtra (3.1%) The median age of typhoid cases was 20 years (IQR 15,29); 67% were male. On admission, 38% of patients had vomiting, 38% had abdominal pain, and 10% of patients (21/200) had diarrhea. While 94% of isolates of *S.typhi* were sensitive to Ceftriaxone and Trimethoprim/sulfamethoxazole and resistant to Ciprofloxacin, 4.6% were sensitive to all the three. No Ceftriaxone resistance was recorded. Contrary to general belief, typhoid did not figure among the major etiologies of AFI in India. However, typhoid may be underestimated in our population as the majority of cases received antibiotics prior to hospital admission. Despite Ciprofloxacin resistance among both *S.typhi* and *S.paratyphi A*, all isolates were susceptible to third generation cephalosporins. Our results highlight the importance of etiological diagnosis at district and sub district healthcare facilities and these results will help in developing clinical guidelines for management of AFI cases.

MONITORING *YERSINIA PESTIS* SUSCEPTIBILITY TO ANTIMICROBIALS IN MADAGASCAR

Faniry Rakotoarimanana, Voahangy Andrianaivoarimanana, Samuel Andrianalimanana, Lila Rahalison, Minoarisoa Rajerison

Institut Pasteur de Madagascar, Antananarivo, Madagascar

Fight against antimicrobial resistance (AMR) is one of this 21th century challenges. Resistance in high pathogenic agent such as *Yersinia pestis*, a potential bioterrorism weapon, is even more a threat for global health. This pathogen continues to threaten the Malagasy population with around 300 reported cases/year. Current treatment regimen in Madagascar consists on high-dose Streptomycin. We present *Y. pestis* resistance to antimicrobial drugs. Also, to provide information on AMR strains will help to adapt treatment recommendations in the the Plague National Control Program (PNCP). This survey was conducted from 1995 to 2017 by the Plague Unit at the Institut Pasteur de Madagascar. Strains were isolated from human biological samples (bubonic and pulmonary plague) as well as rodents and fleas sampled from the field. Antibiotic testing using Kirby Bauer disk diffusion method was performed on each isolated strain. Susceptibility was assessed for Streptomycin, Gentamycin, Tetracycline, *sulfamethoxazole-trimethoprim,* Chloramphenicol, Ampicillin and Ciprofloxacin, and interpretation was done according to Clinical Laboratory Standards Institute guidelines. Among 4812 tested isolates (4364 from humans (H), 438 rodents and fleas (R&F)), *Y. pestis* harboring résistance profile have been identified, among which three strains shows resistance to the drug of choice recommended by the PNCP (Streptomycin), and one with multimicrobial resistance profile. The prevalence of drug resistance is relatively low (0.31%, 15/4812, 13H, 2 R&F), nonetheless it is alarming because of the high risk of dissemination, high mortality rate and the lack of rapid resistance detection tool. *Y. pestis* is classified as category A by the US CDC. Effectiveness of the national network surveillance for *Y. pestis* antimicrobial susceptibility is crucial to detect and monitor the occurrence of resistant strains. There is a need to reinforce capacity in rapid detection of AMR and to update the PNCP treatment recommendation to be aligned with the international guidelines.

1181

CHANGES IN HEALTH CARE SEEKING BEHAVIOR FOR DIARRHEAL ILLNESS IN MALI

Uma U. Onwuchekwa[1], Doh Sanogo[1], Adama M. Keita[1], Boubou Tamboura[1], Moussa Kourouma[1], Anna Roose[2], Helen Powell[2], Milagritos D. Tapia[2], Nasrin Dilruba[2], Samba O. Sow[1], Karen K. Kotloff[2]

[1]Centre for Vaccine Development - Mali, Bamako, Mali, [2]Centre for Vaccine Development, University of Maryland, Baltimore, MD, United States

Diarrheal diseases are a leading cause of child mortality in Africa. Early recognition and seeking timely medical care are very important in preventing diarrheal mortality. To assess trends in health care-seeking behaviour of children under five with diarrheal illness residing in Bamako, Mali, we conducted health care utilization surveys (HUS) several times per year during the Global Enterics Multicenter Study (GEMS, 2009-2010) and, following rotavirus vaccine introduction as part of the Vaccine Impact on Diarrhoea in Africa (VIDA) study (2015-2017). We conducted 3 rounds of HUS during GEMS and 6 rounds during VIDA. For each survey, we randomly selected children in 3 age strata (0-11, 12-23, and 24-59 months) from a censused population and interviewed their primary caretakers. The questionnaire solicited information about a history of diarrhoea illness during the previous 7 days and the use of healthcare facilities. Responses were weighted to reflect the age structure of the underlying population. During the survey rounds conducted from 2009-2010, 3,730 eligible children of which 3,016 (81%) were enrolled. 12% children had a history of diarrheal illness in the past 7 days, of whom 65% sought care outside the home from a medical provider (14%), a pharmacy outside of a medical facility (13%), or a traditional medicine practitioner only (38%); 28% were administered Oral Rehydration Solution (ORS). From 2015-2017, 11895 eligible children of which 10,078 (85%) were surveyed, of whom 2% had a history of diarrheal illness in the past 7 days. 77% of children sought care outside the home from a medical provider (13%), a pharmacy outside a medical facility (29%), or a traditional medicine practitioner provider only (40%); 51% received ORS. The 7-day prevalence of diarrheal disease has decreased in our study area in Bamako. Concomitantly, there is an increase in care seeking related to greater use of pharmacies and uptake of ORS. Introduction of rotavirus vaccine and intensified televised public health messaging about ORS may have contributed to these trends.

1182

IDENTIFICATION AND CHARACTERIZATION OF *ORIENTIA CHUTO* IN TROMBICULID CHIGGER MITES COLLECTED FROM WILD RODENTS IN KENYA

Clement Masakhwe[1], Piyada Linsuwanon[2], Gathii Kimita[1], Surachai Leepitakrat[2], Santos Yalwala[1], David Abuom[1], Nutthanun Auysawasi[2], Tom Gilbreath[1], Elizabeth Wanja[2], John Waitumbi[1]

[1]Medical Research Directorate-Kenya/ Kenya Medical Research Institute, Kisumu, Kenya, [2]US Medical Directorate-Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

We present data that concurs with the reported geographical expansion of scrub typhus outside the "Tsutsugamushi Triangle" and addition of *Orientia chuto* as a second species in the *Orientia* genus. Wild rodents were caught in Marigat, Baringo County, Kenya and ectoparasites, including chiggers recovered. The rodents and the chiggers were speciated by taxonomic features. Genomic DNA was extracted from the chiggers and used to amplify and sequence the 47-kDa (*HtrA*) gene, the 56-kDa (*TSA*) gene and the 16S rRNA. The main rodent hosts identified were *Acomys wilsoni, Crocidura sp* and *Mastomys natalensis* which accounted for 59.2% of the total collection. Of these, *A. wilsoni* and *M. natalensis* harbored most of the chiggers that belonged to the *Neotrombicula* and *Microtrombicula* genera. A pool of chiggers from one of *M. natalensis* was positive for the *Orientia* bacteria by 47-kDa PCR, but did not amplify with the 56-kDa primers. On sequencing the 850 bp of the 47-kDa gene, the closest phylogenetic relative was *O. chuto* with 97.65% sequence homology compared to 84.63 – 84.76% for *O. tsutsugamushi*. 16S rRNA metagenomic sequences also revealed *O. chuto* as the closest phylogenetic relative with 99.75% sequence homology. These results and the existing immunological and molecular reports are strongly suggestive of the existence of scrub typhus in Kenya.

1183

O-SEROGROUPS OF MULTI-DRUG RESISTANT CERVICOVAGINAL *ESCHERICHIA COLI* HARBORING SEVERAL VIRULENCE GENES

Gloria Luz Paniagua Contreras, Eric Monroy Perez, José Rogelio Reyes Solís, Areli Bautista Cerón, Ma. Patricia Sánchez Yañez, Susana González Almazán, Sergio Vaca

UNAM, Tlalnepantla, Mexico

The occurrence of cervicovaginal *Escherichia coli* (CVEC) multi-resistant to antibiotics and harboring several virulence genes is considered a serious health problem. The present study is another effort to determine the antimicrobial susceptibility, the frequency of several virulence genes and the O-serogroups of CVEC strains. Two hundred *E. coli* strains were isolated from Mexican women suffering cervicovaginal infection attending at two medical units of the Instituto Mexicano del Seguro Social at State of Mexico. *E. coli*, the O-serogroups and virulence genes were identified by PCR. Antibiotic susceptibility was determined by Kirby-Bauer disk diffusion test. O25 (50%), O75 (9%), and O15 (7.5%) were the more frequent serogroups. Ninety-eight percent CVEC (n = 197) were resistant to 3-12 antibiotics; 97% were resistant to ampicillin, 93.5% to carbenicillin, 77%

to cephalotin, and 71% to nitrofurantoin. The most frequent virulence genes among the CVEC strains were *feoB* (91.5%), *fimH* (89.5%), *kpsMT11* (75%), *iutA* (66%), and *iron* (59%). This study revealed the main O-serogroups of these multidrug-resistant CVEC strains and their association with the virulence markers. These data can serve to orientate a better antibiotic prescription.

1184

A NOVEL SURFACE-EXPOSED PROTEIN OF *LEPTOSPIRA INTERROGANS* THAT INTERACTS WITH THE COMPONENTS OF HUMAN TERMINAL COMPLEMENT PATHWAY

Maria F. Pereira[1], Aline F. Teixeira[1], Gisele O. Souza[2], Silvio A. Vasconcellos[2], Marcos B. Heinemann[2], **Ana L. Nascimento**[1]

[1]Instituto Butantan, Sao Paulo, Brazil, [2]Universidade de Sao Paulo, Sao Paulo, Brazil

Leptospirosis is a zoonosis globally disseminated caused by pathogenic spirochetes of the genus *Leptospira*. Preventive measures to control leptospirosis are difficult to implement. Thus, understanding leptospiral pathogenic mechanisms is critical for the efficient development of vaccines and diagnostic tests. Our group has identified leptospiral surface proteins with the ability to bind extracellular matrix and plasma/serum components, which could mediate adhesion and facilitate invasion through the hosts. This work aims to assess the role of a probable lipoprotein encoded by the gene LIC13259 of *L. interrogans* in the host immune evasion. The gene LIC13259 was cloned into the expression vector pAE. The plasmid pAE-LIC13259 was employed to transform *E. coli* strains for protein expression studies. In order to assess the localization of LIC13259 at the bacterial surface, ELISA, proteinase K and immunofluorescence assay were performed. The ability of recombinant protein to interact with the complement components was evaluated by ELISA and immunoblotting assay. The effect of LIC13259 on C9 polymerization was assessed by SDS-PAGE. The coding sequence LIC13259 was cloned and expressed successfully in their soluble form. The recombinant protein was purified by nickel affinity chromatography and analyzed by SDS-PAGE (17 kDa). ELISA, proteinase K and immunofluorescence assays suggest the presence of LIC13259 at the cell surface. Furthermore, LIC13259 showed a dose-dependence interaction with the vitronectin, C7, C8, C9 components either purified or from normal human serum. Increasing concentration of heparin had effect on the binding of LIC13259 with vitronectin, suggesting that this interaction involve heparin binding sites. Most interestingly, the LIC13259 was able to inhibit C9 polymerization in a dose-dependent manner. In conclusion, our data suggest that LIC13259 is located at the cell surface and could be involved in host immune evasion processes by interacting with the components of the terminal complement pathway.

1185

ANTIBIOTIC SUSCEPTIBILITY OF THE FIRST *STREPTOCOCCUS CONSTELLATUS* ISOLATED FROM EPIDURAL ABSCESS IN DAKAR

Moustapha Cisse[1], Assane Dieng[1], Serigne ML Ndiaye[1], Khadidiatou Gueye[1], Frederic C. Diaz[1], Samba Diao[1], Safietou Ngom[1], Habsa Diagne[1], Maguette Diop[1], Pape I. Ndiaye[2], Makhtar Camara[1], Cheikh SB Boye[1]

[1]Laboratory of Bacteriology-Virology, Aristide Le Dantec Hospital, Dakar, Senegal, [2]Intensive Care Unit, Aristide Le Dantec Hospital, Dakar, Senegal

Streptococcus constellatus is member of the *Streptococcus anginosus* Group (SAG) that are considered commensal organisms; however, they can sometimes cause serious invasive infections of the liver, lung, brain abscesses, bacteraemia, endocarditis and intra-abdominal infections. *S. intermedius* and *S. constellatus* are the main causes of deep abscess. SAG is generally considered to be susceptible to beta-lactam antibiotics and macrolides; however, increasingly we are seeing the emergence of viridans and beta-haemolytic Streptococci resistant to antibiotics. In a 59-year-old patient hospitalized in intensive unit care for an epidural abscess, pus was collected and cultures were grown. Bacterial identification was performed by routine laboratory methods including Gram stain, catalase reaction and biochemical analysis using the API 20 Strep test (BioMérieux Vitek 2). Antimicrobial susceptibility testing was performed using standard disk diffusion method. Antibiotic disks of penicillin, vancomycin, teicoplanin, gentamycin, erythromycin, lincomycin, pristinamycin, norfloxacin, and rifampicin were placed on inoculated plates. Minimum inhibitory concentration (MIC) was determined by using the BioMérieux Vitek 2. *S.constellatus* was identified in abscess and was resistant to penicillin, aminoglycosides, macrolides, lincomycin, fluoroquinolones. This isolate was sensitive only to vancomycin, pristinamycin and rifampin. Difficulties in identification strains isolates of the SAG have caused confusion in determining their pathogenic potential, but using new powerful tool for rapid identification bacteria, makes accurate diagnosis and differentiatiation possible. Thus, it is necessary to equip the laboratories for good management of infectious diseases. This is the first known report of *S. Constellatus* from abscess in Dakar. SAG are generally susceptible to penicillin, other beta-lactam antibiotics and macrolides. However, in our study *S. Constellatus* were resistant to penicillin, aminoglycosides, macrolides, lincomycin and fluoroquinolones, demonstrating antibiotic resistance among SAG isolates.

1186

MOLECULAR EPIDEMIOLOGY OF LEPTOSPIROSIS IN PERU

Milagros Zavaleta[1], Manuel Céspedes[2], Manuel Ramírez[2], Patricia García[2], Sandra Villar[2], Jorge O. Alarcón[1]

[1]Centro de Investigaciones Tecnológicas, Biomédicas y Medioambientales, Lima, Peru, [2]Instituto Nacional de Salud, Lima, Peru

Leptospirosis represents an important public health problem in Peru (incidence 7 x 100 000 inhabitants). In 2017, 2239 new infections attribute to Leptospira were reported; however, only 50% of the cases were confirmed. Determinant factors of this lack of diagnosis are the location of reference diagnostic center, limitation of diagnostic methods, and limited knowledge of local etiological agent. Besides, a lack of molecular knowledge about the diversity of circulating strains makes difficult the development of new diagnostic tools, treatment or vaccine development. The present work proposes the use WGS-MLST as a tool to give an overview of the genetic diversity and initial epidemiological insights of Peruvian pathogenic Leptospira species and serovars. Ninety-one isolates from the Peruvian National Health Institute strains collection were randomly reactivated. Whole genome sequencing was performed using SBS platform. Genome assembly, annotation, and phylogenetic analysis were performed using free genomic analysis software. MLST data allowed determining 5 species and 12 serovars from 84 isolates. Comparative analysis of leptospiral genomes shows a size of 4.45 Mb with a core comprising 3483 proteins. L. interrogans, L. santarosai and L. noguchi were the most frequent species. Species distribution per time shows that L. interrogans was present in a wide period (2003 - 2013), followed by L. noguchi and L. santarosai. Among five regions of Peru who reported cases of leptospirosis, the majority of species were more frequent in Loreto (approximately 81% of isolates). The molecular identification of Leptospira species in field isolates contributes to increasing the knowledge of genetics and species/serovars distribution.

1187

CHARACTERIZATION OF MULTIDRUG RESISTANT GRAM-NEGATIVE BACILLI FROM HUMAN INFECTIONS IN NICARAGUA

Alexandra W. Dretler[1], Julissa Avila[2], Lisette Sandoval Lira[2], Marcia Garcia Rener[3], Raquel Burger-Calderon[4], Michelle N. Hargita[1], Alexander M. Page[5], Janet Thonkulpitak[5], Jesse J. Waggoner[1], Sarah W. Satola[1]

[1]Department of Medicine, Division of Infectious Diseases, Emory University School of Medicine, Atlanta, GA, United States, [2]Departamento de Bacteriología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua, [3]Sustainable Sciences Institute, Managua, Nicaragua, [4]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, [5]Atlanta Research and Education Foundation, Veterans Affairs Medical Center, Atlanta, GA, United States

Antimicrobial resistance (AMR) represents a global public health crisis; yet much of the burden in limited resource settings remains unknown. In Nicaragua, high rates of AMR have been observed among gram-negative rods (GNRs), though scant data on clinical isolates has been published. The aim of this study was to characterize AMR among GNRs using 100 isolates collected from 6 departments in Nicaragua between 2014 and 2017. Isolates were sent to the Centro Nacional de Diagnóstico y Referencia in Managua, where susceptibility testing was initially performed by the Kirby-Bauer method. We selected 100 isolates with evidence of resistance to ≥ 2 classes of antibiotics, including carbapenems. These represented the most common GNRs identified: *Enterobacteriaceae*, 52 (*K. pneumoniae*, 50; *Escherichia coli*, 4); *A. baumannii*, 30; and *P. aeruginosa*, 16. Isolates were selected predominantly from sterile sites: blood (81 of 96 cultures with specimen recorded), pleural fluid (n=7), cerebrospinal fluid (n=4), peritoneal fluid (n=2), and bronchoalveolar lavage (n=2). Metallo-β-lactamase production was suspected as the primary mechanism of resistance based on imipenem-EDTA synergy disk testing. Carbapenem resistance was confirmed with repeat testing by disk diffusion in all but one isolate (*P. aeruginosa*). Genes for the New Delhi metallo-β-lactamase 1 (NDM-1) carbapenemase were detected in 62% of isolates by real-time PCR, including 50/54 (92%) *Enterobacteriaceae*, 10/30 (33%) *A. baumannii*, and 2/16 (12%) *P. aeruginosa*. The remaining 4 *Enterobacteriaceae* isolates had a *Klebsiella pneumoniae* carbapenemase gene detected. No evidence of colistin resistance was identified. This study reveals very high rates of NDM-1 detection in multidrug-resistant GNRs from Nicaragua, where the enzyme was first identified in a clinical sample in 2012. NDM producing bacteria have spread throughout the world, but little data exists regarding the prevalence of this resistance mechanism in most of Central America. Further research is needed to determine the burden of highly resistant bacteria in Nicaragua and to guide interventions to limit further spread.

1188

PREDICTORS OF GONORRHEA AND CHLAMYDIA AMONG PATIENTS ATTENDING FIVE SELECTED CLINICS IN GHANA

Helena Dela[1], Naiki Attram[2], Eric Behene[1], Kwasi Addo[1], Edward Nyarko[3], Nicholas Kyei[3], John Carroll[3], Cynthia Kwakye[4], Christopher Duplessis[5], Nehkonti Adams[6], Eric Garges[7], Andrew Letizia[2]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]US Naval Medical Research Unit number three, Ghana Detachment, Accra, Ghana, [3]Ghana Armed Forces, Accra, Ghana, [4]Ghana Health Service, Accra, Ghana, [5]Naval Medical Research Center, San Diego, MD, United States, [6]Navy Medicine Professional Development Center, Bethesda, MD, United States, [7]Infectious Disease Clinical Research Program/Uniformed Services University of the Health Sciences, Bethesda, MD, United States

Sexually transmitted infections (STIs) directly affect sexual and reproductive health worldwide. *Neisseria gonorrhoeae*, and *Chlamydia trachomatis* significantly contribute to DALYs. The goal of this study was to identify risk factors associated with the acquisition of gonorrhea and chlamydia in Ghana as well as determine their common clinical symptoms. Participants enrolled presented with symptoms consistent with urethritis or cervicitis were enrolled in some selected health institutions in Sekondi, Takoradi and Accra between June 2012 and March 2016. First void urine samples collected, were tested by a Nucleic Acid Amplification Test (NAAT), to detect both *N. gonorrhea* and *C. trachomatis*. Demographic data was collected and from a structured questionnaire that assessed various social and behavioral characteristics. Nine hundred and fifty individuals comprising 58% females and 42% males were enrolled. A total of 28% tested positive for gonorrhea and 11% for chlamydia, with more males testing positive than females. Commonly reported symptoms among gonorrhea positive patients that demonstrated statistical significance included painful urination and urethral discharge. Additionally, multiple sexual partners, alcohol use, and ages between 25-31 years were statistically associated with higher rates of gonorrhea in males while only the frequency of condom use was associated with gonorrhea in females. The frequency of condom use among females was inversely related to rates of gonorrhea. None of the symptoms or risk factors were associated with testing positive for chlamydia. Individuals presenting with painful urination and discharge in males, were at a higher risk of testing positive for gonorrhea, but not Chlamydia. Risk factors such as multiple sexual partnership, alcohol use and age represent a high-risk group of males who are more likely to test positive for gonorrhea. Identifying these symptoms and risk factors help inform health care delivery systems for STIs in Ghana.

1189

ESTIMATING THE BURDEN OF LEPTOSPIROSIS IN SRI LANKA; A SYSTEMATIC REVIEW

Janith Warnasekara, Iresha Koralegedara, Suneth Agampodi

Department of Community Medicine, Faculty of Medicine and Allied Sciences, Rajarata University of Sri Lanka, Anuradhapura, Sri Lanka

Though Sri Lanka is considered as a hot spot of leptospirosis, true incidence of leptospirosis is unknown. The objective of this study was to provide valid estimates on burden of leptospirosis in Sri Lanka. A systematic review (SR) was carried out using Cochrane guidelines on SR. Pub Med, MEDLINE®, BIOSIS Previews, Zoological Record, Web of Science Core Collection, Current Contents Connect, KCI-Korean Journal Database, BIOSIS Citation Index, Data Citation Index, SciELO Citation Index and Google scholar databases were searched. In addition, quarterly epidemiological bulletin (QEB), Indoor mortality morbidity review(IMMR) and hand search of local literature was done in libraries of SLMA, MRI, PGIM and Universities of Peradeniya and Colombo. Forty relevant full texts, 32 QEBs, and 8 IMMR were included in the full text review. Incidence estimates were based on 87,075 patients reported in IMMR and 45,316 reported in QEB from 2005 to 2015. Adjustments for under diagnosis, underreporting and chance variability were done using the data from prospective studies included in full text review. After the adjustments, estimated annual caseload of leptospirosis was 10,423 and the cumulative annual incidence of leptospirosis that require hospitalization in Sri Lanka during 2008-15 periods was 52.1 (95% CI 51.7-52.6) per 100,000 population. The number of estimated annual deaths due to leptospirosis is around 730 (95% CI 542-980), with an estimated pooled case fatality ratio of 7.0% (95% CI 5.2-9.4). Our SR shows gross underestimation of true leptospirosis burden and this deadly disease needs more attention in the public health agenda.

MULTI-DRUG RESISTANCE SUPPORTED BY PLASMID-ASSOCIATED GENES IN GEORGIA

Nino Trapaidze[1], Nabil H. Latif[1], Maia Nozadze[1], Tinatin Aptsiauri[1], Nino Mitaishvili[1], Nino Butskhrikidze[2], Keto Arobelidze[3], Viktoria Tavadze[3], Tsiuri Simsive[3], Lile Malania[3], Paata Imnadze[3], Michael A. Washington[1]

Infectious threats, and the consecutive emergence and spread of drug resistant bacteria have become a significant global health issue in the 21st century. Antimicrobial resistance (AMR) is steadily increasing in bacterial pathogens and makes treatment a challenging process that often leads to fatal outcomes. It has been estimated that unless hampered, rise of drug resistance will cause up to 10 million deaths a year and excess health-care associated costs in excess of 100 trillion USD by 2050. It has also been suggested, that most direct and indirect effects of AMR will fall on low and middle-income countries. Therefore, a boost in surveillance activities is needed to track the spread of AMR. Georgia, located in the Caucasus region, represents a middle-income country. Importantly, the prevalence and distribution of antimicrobial resistant bacteria in Georgia have not been adequately defined. Therefore there is a significant possibility that Georgia can be heavily impacted by the increasing numbers of multi-drug resistant organisms. The purpose of this study was to detect and examine antibiotic resistance patterns in Georgia. Bacterial isolates, collected at various sites of Georgia, were identified using the automated system Vitek 2. Antimicrobial susceptibilities were determined by both, automated and manual methods (disc diffusion and E-test). Antimicrobial resistance genes were identified by PCR and phenotypic analyses. 100 specimens were collected between July 2017 and February 2018. It was found that 100% of the *Acinetobacter spp.* and *Pseudomonas spp.* isolates were multi-drug resistant. In addition, *Klebsiella spp.* and *Serratia spp.* were found to harbor both, the CTX-M15 extended spectrum beta-lactamase and the OXA-48 carbapenem resistance genes. Multi-drug resistance has been observed in bacterial isolates recovered in the country of Georgia. In addition, detection of highly transmissible plasmid associated resistance genes is indicative of a potential for horizontal spread that in combination with already existing multi-drug resistance could lead to the emergence of a novel "superbug" in Georgia.

DETERMINATION OF EXPRESSION OF EFFLUX PUMPS IN MDR STRAINS OF *ACINETOBACTER BAUMANNII* FROM A TERTIARY CARE HOSPITAL IN LIMA, PERU

Stefany A. Plasencia-Rebata[1], Saúl Levy-Blitchtein[1], Miguel A. Aguilar-Luis[2], William Taboada[3], **Juana M. del Valle-Mendoza**[2]

[1]Universidad Peruana de Ciencias Aplicadas, Lima, Peru, [2]Universidad Peruana de Ciencias Aplicadas, Instituto de Investigación Nutricional, Lima, Peru, [3]Instituto Nacional de Enfermedades Neoplasicas, Lima, Peru

Acinetobacter baumannii is an important nosocomial opportunistic pathogen that has emerged in the clinical setting for its multidrug resistance. It affects mainly patients in intensive care unit. Mortality rates between 7,8-23% and 10-43% in intensive care unit (ICU). It has been reported 30% of multidrug-resistant (MDR) strains in ICU. It is associated with pneumonia, bacteremia, and less frequent with endocarditis, meningitis, and soft tissue injuries. Efflux pumps are divided into 6 superfamilies, between them exist the RND (Resistance-Nodulation-Division) complex that plays and important role in multidrug-resistance. To evaluate the mechanism of efflux pumps, inhibitors of efflux pumps have been used to avoid the exit of diverse molecules. Evaluate and identify the expression of efflux pumps in isolated strains of *A. baumannii* from a tertiary care hospital in Lima between the period of 2014-2016. Clinical isolates of Acinetobacter spp. have been identified by BD Automatized System PhoenixTM, and was confirmed as *A. baumannii* by the amplification of blaOXA-51 gene by PCR. The susceptibility to fluoroquinolones and aminoglycosides was performed by the disc diffusion method and the estimate of the MIC was determined by broth-microdilution, cutoff values were determined according to the CLSI 2018 guidelines. The expression of efflux pumps was analyzed by adding the inhibitor Phenylalanine-arginine β-naphtilamide (PAβN) and it was confirmed its presence if the MIC descend 4 fold times. There were obtained 51 strains positive to *A. baumannii* by PCR *bla*OXA-51. They showed high resistance levels to aminoglycosides: amikacyn was 69,49% (n=41), tobramicyn 67.79% (n=40). Meanwhile, fluoroquinolones: levofloxacin 81.35%(n=48). When PAβN was added to amikacyn it changed to 69,49% (n=41) into 49.15% (n=29). In conclusion, Results obtained suggest efflux pumps were present increasing the susceptibility of amikacin by the use of Phenylalanine-arginine β-naphtilamide (PAβN).

GUT MICROBIOTA IN HOSPITALIZED CHILDREN UNDER FIVE YEARS WITH ACUTE INFECTIOUS GASTROENTERITIS FROM A TEACHING HOSPITAL IN CAJAMARCA, PERU 2011-2012

André A. Taco-Masias[1], Augusto R. Fernandez-Aristi[1], Miguel A. Aguilar-Luis[2], Pablo Weilg[1], Zully Puyén[3], Angela Cornejo-Tapia[1], Erico Cieza-Mora[1], Denisse Champin[4], Jorge Bazán-Mayra[5], Hernán Cornejo-Pacherres[5], **Juana M. del Valle-Mendoza**[1]

[1]Universidad Peruana de Ciencias Aplicadas, Lima, Peru, [2]Universidad Peruana de Ciencias Aplicadas, Instituto de Investigación Nutricional, Instituto de Investigación de Enfermedades Infecciosas, Lima, Peru, [3]Instituto Nacional de Salud, Lima, Peru, [4]Universidad Tecnológica del Perú (UTP), Lima, Peru, [5]Dirección Regional de Salud de Cajamarca, Cajamarca, Peru

Gut microbiota (GM) is a community of microorganisms from in the human gastrointestinal tract (HGIT) which plays a key role maintaining the host health. However, this microbial structure can be disrupted under an inflammatory process such as viral or bacterial infections. The main objective was to describe the gut microbiota profiles in hospitalized children under 5 years with the diagnosis of Acute Infectious Gastroenteritis (AIG). A retrospective, descriptive cross-sectional study was conducted using the Hospital Regional de Cajamarca physicians database between 2011 and 2012. A total of 117 samples from patients under 5 years old with AIG were analyzed for detection of common viral and bacterial etiologies and 13 gut microbiota agents via Polymerase Chain Reaction. Infants younger than 12 months-old were the most predominant age group in 36.7% cases. The most commonly detected microbiota bacteria were: Firmicutes (n=74 cases), Bacteroidetes (n=73 cases), Lactobacillus (n=70 cases), Prevotella (n=67 cases) and Proteobacterium (n=63 cases). Patients with exclusive breastfeeding or mixed feeding registered a higher number of gut microbiota bacteria, compared to those who received formula or were not breastfed. In conclusion, coinfections, type of lactations, nutritional status and the different etiologies altered the gut microbiota profiles in children under 5 years old.

MAKING A MASS DRUG ADMINISTRATION (MDA) PARTICIPATOR: IDENTIFYING FACTORS ASSOCIATED WITH MDA PARTICIPATION FOR TRACHOMA CONTROL IN AMHARA, ETHIOPIA

Caleb D. Ebert[1], Tigist Astale[2], Eshetu Sata[2], Mulat Zerihun[2], Andrew W. Nute[1], Aisha Stewart[1], Demelash Gessesse[2], Gedefaw Ayenew[2], Zebene Ayele[2], Melsew Chanyalew[3], Zerihun Tadessee[2], E. Kelly Callahan[1], Scott D. Nash[1]

[1]The Carter Center, Atlanta, GA, United States, [2]The Carter Center, Addis Ababa, Ethiopia, [3]Amhara Regional Health Bureau, Bahir Dar, Ethiopia

Mass drug administration (MDA) with azithromycin is a core part of the WHO recommended strategy to eliminate trachoma as a public health problem, but low participation rates in MDA campaigns may undermine the effectiveness of this intervention. Following an MDA in Amhara, Ethiopia in May 2017, we conducted multi-level cluster random coverage surveys in 4 districts to collect data on self-reported MDA participation. We then explored predictors for individual MDA participation at the individual, household, and guardian levels. Random-effects logistic regression modeling was used to identify predictors of MDA participation while adjusting for nesting of individuals within households. A total of 100 clusters were surveyed, which we obtained data on 6613 participants from 1629 households. The district-level self-reported MDA participation ranged from 78.5% to 86.9%. We developed a model for all participants and found several positively-associated factors for MDA participation: excellent and fair health status (Odds Ratio [OR] = 7.30; 95% Confidence Interval [CI]: 2.62, 20.33; OR = 9.35; 95% CI: 3.06, 28.55), length of household's residency (OR = 2.34; 95% CI: 1.32, 4.17), advanced knowledge of the MDA campaign (OR = 4.28; 95% CI: 2.62, 6.98), and knowledge of trachoma (OR = 1.67; 95% CI: 1.05, 2.67). A second model was run, which excluded heads of household and included head of household participation in the model. Factors associated with participation were similar to those found in the first model, in addition to the head of household participation (OR = 6.03; 95% CI: 3.90, 9.30). Conversely, older age (OR = 0.98; 95% CI; 0.98, 0.99) was negatively associated with participation. These results offer exploratory insight into the factors associated with MDA participation in Amhara, and suggest that heads of households hold a strong influence over their household's participation. To ultimately increase the coverage in Amhara, MDA mobilization strategies – inclusive of comprehensive trachoma and azithromycin messaging and MDA campaign awareness – should target heads of households as well as new residents and those in poorer health and older age.

THE PREVALENCE, RISK FACTORS AND SEROTYPES DISTRIBUTION OF TRACHOMA IN LAIKIPIA, KENYA 2017

Stephen Mwatha

Neglected tropical medicine, Nairobi, Kenya

Trachoma is one the leading causes of preventable blindness caused by a bacterial infection known as Chlamydia trachomatis. It is a Neglected Tropical Disease (NTDs) spread from person to person through direct contact with discharges from infected eye and nose, through mechanical vectors like flies or by contact with fomites. There are various serotypes of Chlamydia trachomatis, serotypes A, B, Ba, and C cause eye infections whereas serotype D and K cause genital infections. The objective of this study will be to determine prevalence and factors associated with Trachoma occurrence, transmission and to document the human Chlamydia trachomatis serotypes and their distribution in Laikipia County. This Will be a cross-sectional community-based survey, estimate the prevalence of TT in adults ages above 15 years old and trachomatous inflammation—follicular in children 1-9 years old. Multi-stage cluster sampling will be done using the existing trachoma clusters. The World Health Organization guidelines on mapping. an evaluation unit (EU) is a considered an administrative unit with a population of 100,000-250,000 persons for healthcare management. Twenty-five to thirty clusters will be randomly selected in each survey segment as recommended by World Health Organization. In each cluster, 30 households will be selected, and all residents living in those households ages one year and above will be invited to participate voluntarily. Participants will be examined by Tropical Data-certified graders, using 2.5× magnifying loupes under direct sunlight. In addition, the certified recorder will conduct direct observation and administer a standardized questionnaire on household-level data on access to water and sanitation.The finding of this study will be used to inform on the progress made in the elimination of trachoma in Laikipia county where the SAFE strategy has been under implementation. It will also bring new knowledge on the existing serotypes and their distribution and correlate the laboratory and clinical diagnosis. Results will inform policy and will be disseminated through workshops, conferences, and publications.

Trachoma impact surveys (TIS) rely on the field grading of clinical signs of the disease using the World Health Organization's recommended simplified grading system as a tool for assessing clinical signs. Conjunctival clinical signs diagnosed by this system include: trachomatous inflammation - follicular (TF), trachomatous inflammation - intense (TI) and trachomatous scarring (TS). Before each TIS conducted in Amhara, Ethiopia since 2010, graders received training for 7-10 days consisting of classroom and field practice followed by a slide exam. Trainees who passed the slide exam moved on to take a field reliability exam. The field exam included grading the conjunctivae of both eyes from 25 children ages 1 to 9 years and were designed to test the ability of graders to diagnose TF, however, the accuracy of TI and TS diagnoses were also assessed. To participate as a grader, trainees were required to achieve a ≥ 84% agreement and a Cohen's kappa (κ) of ≥ 0.7 with TF compared to the consensus grade of three master trachoma graders. Graders were allowed up to 3 attempts to pass a field exam and all rounds of field exams use a unique set of children. Using the collective data from the passing field exam of all passing trainees for a given TIS, a group agreement and κ was calculated for each clinical sign to allow for comparisons between the groups of graders from different trainings. Graders that participated in multiple TIS from 2011-2017, had their data from different surveys treated as independent resulting in a total of 204 trainees taking a field reliability exam. Mean group size was 23 trainees (Standard Error (SE): 3) per survey. A mean of 63.4% (SE: 5.2%) of trainees per survey passed an exam, totaling 124 trainees. The mean group agreement and κ was: 89.1% TF agreement, 0.78 TF κ; 86.9% TI agreement, 0.58 TI κ; 94.5% TS agreement, 0.72 TS κ. The range of group TF reliability results across trainings was 86.9% (group κ: 0.74, n=20) to 96.0% (group κ: 0.92, n=8). Over 7 years, the Trachoma Control Program in Amhara has trained a large cadre of qualified trachoma graders and has demonstrated the ability to consistently achieve high reliability in grading TF.

1196

MASS AZITHROMYCIN DISTRIBUTION FOR TRACHOMA CONTROL AND SELECTION FOR ANTIBIOTIC RESISTANCE: A SYSTEMATIC REVIEW

Kieran S. O'Brien[1], Paul Emerson[2], Elena G. Davis[1], Jeremy D. Keenan[1], Thomas M. Lietman[1], Catherine E. Oldenburg[1]

[1]University of California San Francisco, San Francisco, CA, United States, [2]International Trachoma Initiative, Decatur, GA, United States

Mass distribution of azithromycin is effective for controlling trachoma and has been shown to reduce childhood mortality. As mass azithromycin is considered for child survival more broadly, understanding the potential for the selection of macrolide resistance is essential. In this systematic review, our objective was to synthesize existing evidence on macrolide resistance following mass azithromycin distribution. We searched electronic databases for articles and conference abstracts published through September 13, 2017 and we contacted authors of included papers to identify unpublished data. We included studies on the community-wide distribution of oral azithromycin for trachoma that included measures of prevalence of carriage and macrolide resistance for any organism. Heterogeneity in study design, setting, treatment frequency, and follow-up precluded formal meta-analysis. We identified 196 studies overall and 19 met inclusion criteria for this review. Twelve studies assessed resistance in *Streptococcus pneumoniae*, 3 in *Chlamydia trachomatis,* 3 in *Escherichia coli*, 2 in *Staphylococcus aureus,* and 1 in *Plasmodium falciparum.* Several studies on *S. pneumoniae* found increases in resistance immediately after mass azithromycin, with subsequent decreases to near baseline levels over time. Some evidence of resistance was found in *E. coli* and *S. aureus*. No resistance was identified in *C. trachomatis* or *P. falciparum.* The lack of resistance seen in *C. trachomatis* is encouraging as it provides evidence that mass azithromycin may remain effective for trachoma control. As mass azithromycin distributions continue for trachoma and are considered for broader interventions, ongoing monitoring of resistance in multiple organisms is required to mitigate unintended adverse effects.

1197

UNDERSTANDING TRACHOMA TRANSMISSION DYNAMICS AT LOW PREVALENCE LEVELS: THE TIMESCALES OF INFECTION AND DISEASE PROVIDE DIFFERENT SIGNALS BEFORE AND AFTER HAULTING INTERVENTIONS

Amy Pinsent, Robin Bailey, Deirdre Hollingsworth

London School of Hygiene & Tropical Medicine, London, United Kingdom

Trachoma remains the world's leading infectious cause of blindness, with an estimated 160 million people at risk of blindness. With falling levels of infection across multiple populations, the program is faced with a classic challenge of how to measure low levels of prevalence within the restricted technicaland budgetary options. For trachoma in particular, it can be challenging to verify elimination as, despite limited-to un-detectable PCR positivity, TF prevalence can persist around the target level of <5% for extended periods. In this study we use a validated transmission model to explicitly model the proportion of individuals in the community that were PCR only positive, those TF and PCR positive andthose only TF positive. We evaluatedhow the expected proportion of individuals in each diagnostic state changedover: a 3 year intervention period, 2 years after the implementation of an intervention program and during the endgame phase of elimination. To assess whether what we observed in our simulation model was correct we validated our model findings using paired individual level PCR and TF prevalence data from 4000 individuals across 5 different trachoma endemic or formally endemic regions: Kiribati, Solomon Islands, Ghana, Nepal and The Gambia. Our results suggested that at low-levels of prevalence the relationship between may be more linear when we account for the diagnostic state of individuals instead of aggregating the data at the community level. Disparities in prevalence estimates at low-levels of transmission could be an artifact of sampling size if the study is not sufficiently powered to determine very low-levels of PCR positivity. Our results suggested that a clearer understanding of the dynamics of infection can be understood from harnessing the power of individual level data that it routinely collected to understand the proportion of individuals in each diagnostic state, instead of only aggregate measures of PCR and TF prevalence. Despite the time lag to clear disease, TF prevalence is a more sensitive indicator of a community's elimination status when resources are constrained and is a more reactive indicator of re-emergence.

1198

RESULTS OF A TRACHOMATOUS TRICHIASIS SURGICAL QUALITY AUDIT IN TANZANIA

Jennifer C. Harding[1], Joyce Lyamuya[1], Erin Smith[1], Dr. Paul Courtright[2], Dr. Yaobi Zhang[3], Dr. George Kabona[4], Dr. Upendo Mwingira[5]

[1]Helen Keller International, Dar es Salaam, United Republic of Tanzania, [2]Sightsavers, Haywards Heath, United Kingdom, [3]Helen Keller International - Regional Office for Africa, Dakar, Senegal, [4]Iringa Regional Referral Hospital, Iringa, United Republic of Tanzania, [5]National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania

A trachomatous trichiasis (TT) surgical quality audit was performed in Tanzania in August 2017. The goal of the audit was to identify surgeons requiring further training or removal from the program, and to evaluate quality outcomes program-wide. The audit was performed by Tanzania Ministry of Health TT Technical Supervisors. A random sample of patients treated by each of the 14 surgeons were selected using the Lot Quality Assurance Sample for Audits (LQAS) sampling procedure and examined for any post-operative trichiasis (PTT) and other poor surgical outcomes. The corresponding surgeons were classified into "high PTT rate" and "low PTT rate" groups rather than estimating actual PTT rates. The Tanzania Trachoma Technical Working Group (TTWG) established a rate of 20% as the highest acceptable rate of PTT for a surgeon; thus a sample size of 30 patients per surgeon was required with a maximum of 5 PTT cases allowed in the sample. A total of 388 patients were seen, and 404 eyes analyzed. Two surgeons were found to have a high rate of PTT. Furthermore, although it was not the primary outcome of interest, one surgeon was found to have unusually high rates of granuloma, severe over-correction, and eye contour abnormality (2, 4, and 10 patients respectively). After a review of the results by the TTWG, all three surgeons with poor outcomes were scheduled for an immediate supportive technical supervision visit from a TT Master Trainer before performing more TT surgeries, with further technical supervision visits as needed, and all three surgeons will be re-audited in six months. Overall, the surgical audit showed that most surgeons performing TT surgery had acceptably low PTT rates, and successfully identified the surgeons who were in need of further support and re-training. The audit protocol itself was found to be accessible and easy to follow, although some minor improvements to the method will be made before the next round of audits. Surgical audit was found to be a useful tool to provide additional support to surgeons needing technical improvements and to improve TT surgery outcomes in Tanzania.

THE TRACHOMA ENDGAME IN NEPAL: TRACHOMATOUS TRICHIASIS-ONLY SURVEYS TO SUBSTANTIATE ELIMINATION AS A PUBLIC HEALTH PROBLEM

Jeremiah M. Ngondi[1], Shekhar Sharma[2], Sailesh Mishra[2], Raman D. Prasad[3], Achut B. Ojha[3], Sudip Khatiwada[3], Joshua Sidwell[4], Mike French[5], Lisa Rotondo[5], Rob Henry[6], Aryc Mosher[6], Ana Bakhtiari[7], Rebecca Willis[7], Emma Harding-Esch[8], Anthony W. Solomon[9]

[1]RTI International, Dar Es Salaam, United Republic of Tanzania, [2]Nepal Netra Jyoti Sangh, Kathmandu, Nepal, [3]RTI International, Kathmandu, Nepal, [4]RTI International, Research Triangle Park, NC, United States, [5]RTI International, Washington, DC, United States, [6]United States Agency for

International Development, Washington, DC, United States, [7]Task Force for Global Health, Atlanta, GA, United States, [8]Clinical Research Department, London School of Hygiene & Tropical Medicine, London, United Kingdom, [9]Department of Control of Neglected Tropical Diseases, World Health Organization, Geneva, Switzerland

Trachoma was endemic in Nepal. The surgery, antibiotics, facial cleanliness and environmental improvement (SAFE) strategy was implemented from 2002-2017. By August 2017, Nepal had drafted a dossier to request validation of elimination of trachoma as a public health problem. However, elimination of trachomatous trichiasis (TT) was uncertain in 12 districts where previous trachoma rapid assessments had demonstrated a measurable burden of TT (8 districts) or baseline surveys had shown TT prevalence to be >0.2% in ≥15-year-olds (4 districts). We describe the methodology and results of TT-only surveys undertaken to investigate if the TT elimination prevalence threshold (<0.2% in ≥15-year-olds) had been attained. Surveys were undertaken in 14 evaluation units (EUs) following the Tropical Data methodology. The sample size was calculated to estimate, with 95% confidence, an expected TT prevalence of 0.2% with absolute precision of 0.2%, a design effect of 1.47, yielding 2,818 as the minimum number of adults aged ≥15 years to be examined. Two-stage cluster sampling was used, whereby in each EU, 20 to 30 *wards* (clusters) were systematically selected with probability proportional to population size and 40 households selected in each cluster using the compact segment method. Training of trachoma graders was completed using Tropical Data methods for TT-only surveys. Only people aged ≥15 years were invited to be examined. Prevalence of TT was adjusted for age and gender. A total of 44,140 eligible participants were examined for TT, a slight majority (56%) of whom were female. TT prevalence by EU ranged from 0-0.10% (95% confidence interval 0.01-0.20). Accounting for TT known to the health system, TT prevalence ranged from 0% to 0.07%. Findings suggest all surveyed EUs had attained the elimination threshold for TT. These surveys provide important evidence for substantiating the claim of elimination of trachoma as a public health problem in Nepal.

ELIMINATION OF TRACHOMA THE SAFE WAY IN NEPAL: KEY PROCESSES AND MILESTONES

Achut B. Ojha[1], Shekhar Sharma[2], Sailesh Misra[2], Raman D. Prasad[1], Sudip Khatiwada[1], Kathryn Crowley[3], Joshua Sidwell[4], Mike French[3], Lisa Rotondo[3], Rob Henry[5], Aryc Mosher[5], Jeremiah M. Ngondi[6]

[1]RTI International, Kathmandu, Nepal, [2]Nepal Netra Jyoti Sangh, Kathmandu, Nepal, [3]RTI International, Washington, DC, United States, [4]RTI International, Kathmandu, NC, United States, [5]United States Agency for International Development, Washington, DC, United States, [6]RTI International, Dar Es Salaam, United Republic of Tanzania

Trachoma was endemic in Nepal where implementation of the surgery, antibiotics, facial cleanliness and environmental improvement (SAFE) strategy was undertaken from 2002 to 2017. We describe: baseline surveys; implementation of SAFE; impact and surveillance surveys; and preparation of dossier for validation of elimination in Nepal. Data were collated from reports of SAFE implementation, scientific manuscripts, water sanitation and hygiene strategies (WASH), and national development plans. The trachoma elimination dossier narrative and data templates were completed according to the World Health Organization standard operating procedures. Trachoma rapid assessments (TRA) were done from 1996 to 2008 covering 57 districts and informed where further baseline surveys were required. A total of 53 districts were surveyed at baseline of which 20 were eligible for the AFE components of SAFE. A total of 29,468 trichiasis surgeries were done from 2002 to 2017. Annual mass drug administration (MDA) was undertaken from 2002 to 2014 in 20 districts. Implementation of facial cleanliness and environmental change (F&E) was targeted to trachoma endemic districts and nationally through WASH programmes. Impact surveys showed that all 20 eligible districts had achieved elimination of TF (<5%) and surveillance surveys showed that TF prevalence of <5% had been maintained 24 months after the impact surveys. A total of 12 districts were eligible for trichiasis only surveys because TRA results suggested that trichiasis was a public health problem (8 districts) and baseline surveys has showed trichiasis prevalence was >0.2% (4 districts). Trachoma dossier preparation started 6 months before the final surveys were conducted and took a year and half from start to submission. Nepal has made steady progress towards elimination of trachoma. The Nepal case study provides important lessons for other national programmes on implementation of SAFE and trachoma elimination.

1201

REACHING DISTRICT ELIMINATION THRESHOLDS, HOUSE BY HOUSE: A NEW APPROACH TO CASE FINDING FOR TRICHIASIS SURGERY IN OROMIA REGION, ETHIOPIA

Zelalem Jemal[1], Abdi Yuya[1], Ahmed Aliyi[2], Mustafa Abamilki[1], Alemu Gemechu[1], Sherif Ahmed[1], Anne Heggen[1], Paul Courtright[3], Sarity Dodson[4]

[1]The Fred Hollows Foundation, Addis Ababa, Ethiopia, [2]East Hararghe Zonal Health Department, East Hararghe, Ethiopia, [3]Kilimanjaro Centre for Community Ophthalmology, Moshi, United Republic of Tanzania, [4]The Fred Hollows Foundation, Melbourne, Australia

Oromia Region is the most trachoma-endemic region, in the most trachoma-endemic country globally and over 25 million people live in 216 trachoma endemic districts. In partnership with the Oromia Regional Health Bureau (ORHB), The Fred Hollows Foundation (FHF) has cleared nearly 65% (90,000 surgeries) of the TT backlog in the region. As districts approach elimination, case finding has become significantly more challenging. Those left untreated are typically those in remote areas, the immobile, and those reluctant to participate in surgery. The need for a more intensive and proactive approach to case finding has been identified. The current project sought to test the efficacy and cost of a systematic house to house approach to case finding. Focusing on rural areas of two districts (Haro Maya and Kombolcha) a team of health extension workers (HEWs) were trained and mobilised to visit each house in a designated area. The HEWs were closely supported and supervised to meet daily targets by Primary Health Care Unit Directors (PHCUD). In turn, daily targets were cascaded from PHCUDs to Woreda Health Office staff to Zonal staff. Collectively this highly organised, coordinated effort sought to ensure each HH was visited and each suspected TT case was actioned. Efforts are ongoing, but as of April 1st, HEWs have visited 62,212 households (HHs) in Haro Maya (80% of HHs), identifying 559 suspected TT cases (255 confirmed; 562 required to reach elimination). In Kombulcha, 38,764 HHs have been visited (90%), identifying 232 suspect cases (186 confirmed; 146 required to reach elimination). Surgeries are ongoing. These districts are expected to clear their TT backlog in May. The cost of the house to house approach per district is estimated to be $6000. Results suggest the house to house approach is an effective and efficient way to reach those 'hard to reach' and reluctant to participate in outreach services. Future plans include examining the feasibility of applying the strategy in low versus high backlog areas, the impact of providing low cost ophthalmoscopes to aid case finding, and exploring opportunities to integrate case finding with other health care activities.

1202

COMPLETING TRACHOMA BASELINE MAPPING IN UGANDA RESULTS OF SURVEYS IN 14 POPULATION BASED SURVEYS CONDUCTED IN 2014 AND 2018

Gilbert Bayeenda[1], Francis Mugame[1], Patrick Turyaguma[1], Edridah Tukahebwa[1], Benjamin Binagwa[2], Ambrose Onapa[2], Stella Agunyo[2], Martin Klaus[2], Michael French[2], Wangeci Thuo[2], Jeremiah Ngondi[3]

[1]National Ministry of Health, Kampala, Uganda, [2]RTI International, Kampala, Uganda, [3]RTI International, Dar Es Salaam, United Republic of Tanzania

Trachoma is endemic in 46 districts of Uganda where implementation of the SAFE strategy (surgery, antibiotics, facial cleanliness, environmental improvement) started in 2007. Some districts neighbouring known endemic areas had not previously been mapped. We aimed to estimate the prevalences of trachomatous inflammation-follicular (TF) and trichiasis in those districts. Population-based prevalence surveys were undertaken in 14 evaluation units (EUs) covering 12 districts. The sample size was calculated assuming an expected prevalence of 10% with absolute precision of ± 3%, at 5% level of significance, 95% level of confidence using, a design effect of 2.71 and inflation by 1.15 to account for 15% non-response. Therefore a minimum sample of 1,200 children aged 1-9 years was required in each EU. In each EU, two-stage cluster sampling was used to select the sample. Consenting participants aged 1 year and above were examined for trachoma using the World Health Organization simplified grading system. Prevalence estimates were adjusted for age and gender. A total of 11,796 households were surveyed, and 47,117 people were examined for TF and trichiasis signs. EU-level TF prevalence in children aged 1-9 years ranged from 0.3 (95% confidence interval [CI] 0.1-0.7) to 3.9% (95% CI 2.1-5.8). Among adults aged ≥15 years, trichiasis prevalence ranged from 0.03 (95% CI 0-0.09) to 0.65% (95% CI 0.25-1.31). Trachoma was not a public health problem in 8 of 14 EUs surveyed. In four EUs, trichiasis prevalence in adults aged ≥15 years was ≥0.2%, thus further trichiasis surgery interventions at public health-level are warranted to achieve elimination. These findings will facilitate planning for elimination of trachoma in Uganda.

1203

THE "LAST MILE" OF TRICHIASIS MANAGEMENT IN CAMEROON: ALIGNING IMPLEMENTATION AND EPIDEMIOLOGICAL DATA AT THE THRESHOLD OF TRACHOMA ELIMINATION

Assumpta Lucienna Bella[1], Emilienne Epée[1], Julie Akame[2], Yannick Nkoumou[2], Michel Hendji[2], Medesse Sonou[3], Stephanie Parker[3], Whitney Goldman[3], Stefania Slabyj[3], Emily Gower[4]

[1]Ministry of Public Health, Yaounde, Cameroon, [2]Helen Keller International, Yaounde, Cameroon, [3]Helen Keller International, New York, NY, United States, [4]University of North Carolina, Chapel Hill, NC, United States

In trachoma elimination programs, epidemiological surveys guide service provision and demonstrate evidence of progress towards elimination. In partnership with the Cameroon Ministry of Health, the USAID-funded Morbidity Management and Disability Prevention (MMDP) Project uses survey data to plan its provision of intensive trachomatous trichiasis (TT) management services in two regions of the country. As Cameroon is in the 'last mile' of TT elimination, TT management services are carefully coordinated with epidemiological surveys as districts approach the elimination threshold. Survey estimates of TT cases, however, sometimes do not match with the number of cases found at the community-level, as demonstrated in Touboro district in the North region of Cameroon. In 2016, trachoma impact survey data demonstrated a TT prevalence of 0.48% in adults >15 years, resulting in an age-and sex-standardized backlog of ~438 people. The MMDP Project then supported a TT campaign with robust, district-wide social mobilization, trained traditional healers to identify and refer TT cases, and organized community meetings in all 12 of the district's health areas. This effort identified 117 TT cases, of which 104 received surgery. In November 2016, the national program conducted a TT-only survey in Touboro, using WHO's Tropical Data platform. Given the prior investment in TT case identification, the program anticipated finding few unidentified TT cases. Preliminary results showed a TT prevalence of 0.77% in adults >15 years, suggesting a backlog of >1,000 people unknown to the health system. In response, additional social mobilization and outreach were conducted in 2017 in four of the district's 12 health areas, identifying only 55 TT cases (54 received surgery). Two campaigns are planned for 2018 to provide services to the district's remaining health areas, though they may yield a low number of cases. The Touboro experience raises the challenge of determining appropriate next steps for program implementers, as findings from implementation do not always align with the latest surveys that may produce wide confidence intervals and imprecise backlog figures.

1204

WATER SANITATION AND HYGIENE (WASH) IMPACT ON THE ELIMINATION OF TRACHOMA: POSITIVE CHANGES BETWEEN IMPACT AND SURVEILLANCE SURVEYS IN TANZANIA

Alistidia Simon[1], George Kabona[1], Jeremiah Ngondi[2], Mathias Kamugisha[3], Upendo Mwingira[1], Andreas Nshala[4]

[1]Tanzania Neglected Tropical Disease Control Program, Dar es Salaam, United Republic of Tanzania, [2]RTI International, Dar es Salaam, United Republic of Tanzania, [3]National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania, [4]IMA World Health, Dar es Salaam, United Republic of Tanzania

The World Health Organization (WHO) recommends a surveillance survey after two years after the last trachoma impact survey which showed a result of trachomatous inflamation - folicular (TF) prevalence < 5%. Both surveys evaluate the prevalence of TF, trachomatous trichiasis (TT) and water sanitation and hygiene (WASH) indicators. The Tanzania Neglected Tropical Disease Control Program (TZNTDCP) investigated the prevalence of TF and TT in people aged ≥1 in six districts. Impact surveys were completed in 2015 and surveillance surveys in 2018. Two-stage cluster survey sampling was used, and households were selected using systematic random sampling. In sampled households, all people aged ≥1 were examined for TF and TT using the WHO simplified trachoma grading system. Heads of households were interviewed on sanitation and hygiene facilities. Results from the 2015 impact survey showed Masasi TC had the highest proportion of people using an improved water source (51.4%) followed by Newala DC (37.8%), Mtwara DC (30.4%), Masasi DC (26.6%) and Tandahimba DC (25.5%). Only 8.8% of Nanyumbu DC population reported to be using protected/improved water sources. Approximately two years later (2018) the surveillance survey showed an increased proportion of the population using improved water sources compared to the impact surveys. Results included the following: Newala (44.24%), Mtwara DC (57.66%), Masasi DC (38.44%), Tandahimba (34.16%), and Nanyumbu (18.8%). There was no significant change in water source status in Masasi TC despite having a high proportion of population using improved water source two years earlier. This improvement in water source has significantly contributed to keeping the TF prevalence to less than 5% as evidenced by surveillance surveys. The results suggest that WASH activities are being undertaken in these formerly endemic districts which have attained the criteria for stopping mass drug administration to prevent trachoma.

1205

TRICHOMONAS VAGINALIS INFECTION IN SOUTHERN GHANA: AS SOCIATED RISK FACTORS, CLINICAL CHARACTERIZATION AND OUTCOMES

Daniel S. Squire[1], Alan J. Lymbery[1], Habib Ahmed[2], Richard Harry Asmah[3], Rca Andrew Thompson[1]

[1]Murdoch University, Western Australia, Australia, [2]Sogakope District Hospital, Sogakope, Ghana, [3]School of Biomedical and Allied Health Science, University of Ghana, Accra, Ghana

Trichomonas vaginalis is the causative agent for the most prevalent non-viral sexually transmitted infection (STI) among women and the infection is associated with varied clinical presentations and outcomes. We conducted a cross-sectional study on 479 women visiting gynaecological and STI clinics in Southern Ghana between January and April 2016 to assess the risk factors associated with *T. vaginalis* and clinically characterize the infected groups. Vaginal samples were analysed using wet preparation microscopy and polymerase chain reaction (PCR). Of the 479 women, 63 (13.2%; 95% CI 9.5-17.6) and 78 (16.8%; 95% CI 12.2-21.1) had *T. vaginalis* infection based on wet preparation and PCR respectively, and diagnosis by PCR was significantly more sensitive ($P < 0.0001$). Univariate analyses found that *Trichomonas vaginalis* infection was significantly associated with vaginal itch (OR = 1.38, $P = 0.04$), oral sex (OR = 1.10, $P = 0.04$) and a prior history of stillbirth (OR = 3.62, $P = 0.04$). We used a model averaging approach to examine the relationship between *T. vaginalis* infection and predictor variables for clinical signs and risk factors. Vaginal itch was ranked highest in variable importance for clinical signs, occurring in 62% of the top eight models; discharge colour and discharge consistency were other variables also occurring in the top set of models. Scores were assigned based on the presenting clinical signs to categorise the pathogenicity levels of *T. vaginalis* into four groups; 6 (6.7%) corresponded to non-pathogenic group, 21 (23.6%) to the very low pathogenic, 39 (43.8%) to the low pathogenic and 12 (13.5%) to the high pathogenic group. A history of engaging in oral sex was ranked highest in variable importance for risk factors, occurring in 72% of the top-ranked models; cleaning material used after toileting and educational level also appeared in more than 50% of the top-ranked models. The varied clinically characterized groups suggest the existence of genetic polymorphism in the *T. vaginalis* infecting these individuals. Keywords: *Trichomonas vaginalis*, Women, Southern Ghana

1206

SUCCESSFUL INTRODUCTION OF AN ANTIMICROBIAL STEWARDSHIP PROGRAM TO IMPROVE ANTIBIOTIC USAGE IN A LARGE, URBAN HOSPITAL IN BLANTYRE, MALAWI

Rebecca Lester[1], Kate Haigh[1], Akuzike Kalizangoma[2], Jane Mallewa[3], Mulinda Nyirenda[3], Melita Gordon[4], Nicholas Feasey[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]Malawi-Liverpool Wellcome Trust, Blantyre, Malawi, [3]University of Malawi, College of Medicine, Blantyre, Malawi, [4]University of Liverpool, Liverpool, United Kingdom

Ceftriaxone is the first and last-line broad-spectrum antibiotic available for treatment of sepsis in Blantyre, Malawi, where there has been a recent, rapid spread of extended spectrum beta-lactamase (ESBL) producing Enterobacteriaceae isolated from blood cultures. Antibiotic misuse is a major driver of antimicrobial resistance (AMR), yet there are little data on stewardship from low-income countries and none from Malawi, where there are challenges both in achieving timely access to antimicrobials and in preventing emergence of AMR. This study describes the first introduction of an antimicrobial stewardship programme to the largest government hospital in Malawi, and its effect on ceftriaxone prescriptions. An antibiotic prescribing survey was carried out on the medical wards prior to the introduction of an antibiotic guideline. The guideline was written by a committee of locally experienced physicians and microbiologists, and took the form of a smart-phone application (MicroGuide). Weekly point prevalence surveys of ceftriaxone usage were carried out and presented to prescribers with reminders to review all antibiotic prescriptions at 48-hours. Antibiotic prescribing surveys were repeated 3 months and 2 years after guideline introduction. Prior to the guideline, 80.0% of all antibiotic prescriptions were for an intravenous 3rd generation cephalosporin, falling to 62.7% (percentage difference 17.3 [95% CI, 6.7-27.9, p<0.01]) at 3 months and to 55.5% (percentage difference 24.5 [95% CI, 2.7-15.6, p=0.01]) 2 years after guideline introduction. The proportion of 48-hour reviews increased from 62.2% to 93.3% (percentage difference 31.1 [95% CI 23.0-39.3, p<0.01]). Mortality did not change over the study period. We report the first successful introduction of a low-cost antimicrobial stewardship approach in Malawi. An antibiotic guideline, supported by weekly 'reminders' led to a reduction in ceftriaxone usage and an increase in antibiotic reviews. This study provides urgently needed feasibility data to support larger scale stewardship interventions in this and other resource-limited settings.

1207

INDUCING IRON DEFICIENCY IN TRANSGENIC SICKLE MICE: WILL LESS BE BETTER?

Majed N. Almashjary, Steven Brooks, Hans Ackerman

National Institutes of Health, National Institute of Allergy and Infectious Diseases, Rockville, MD, United States

Sickle cell disease (SCD) is caused by polymerization of deoxygenated hemoglobin-S (HbS) within the red blood cell (RBC). The kinetics of hemoglobin polymerization are dependent on the intra-erythrocytic concentration of HbS; specifically, the time from deoxygenation to polymerization is inversely related to HbS concentration[30]. Iron-deficient erythropoiesis (IDE) produces RBCs with decreased intracellular Hb concentration, which could reduce sickling and reduce the severity of SCD. In a pilot experiment, we determined the effect of dietary iron restriction on erythropoiesis in mice. Six-week-old female C57Bl/6J mice (Jackson Labs) were fed iron-restricted or control diet for 12 weeks. Complete blood count (CBC) results were obtained by Advia® 120 Hematology System, and erythropoietin was measured by ELISA. In iron-restricted mice, RBC parameters including MCV, MCH, MCHC, and reticulocyte hemoglobin content were all decreased over time. Total hemoglobin, reticulocyte percentage, RBC count, red blood cell distribution width (RDW), and platelet count remained constant. Erythropoietin levels were unchanged by iron restriction. Next, we will investigate the impact of dietary iron restriction on hematologic and pathologic endpoints in a transgenic mouse model of SCD. Townes SCD mice will be fed custom diets (AIN-93G, Research Diets, Inc.) containing either 3 ppm iron or 48 ppm iron and followed over a period of 6 months. We will monitor hemoglobin, hematocrit, MCHC, and sickling time longitudinally at 2, 4, and 6 months. At month 6 we will examine pathologic endpoints including markers of hemolysis and organ damage to brain, liver, and kidney. This study will provide a picture of the hematologic changes that occur in blood during the onset of iron deficiency anemia and evaluate the potential of iron deficiency to delay sickling and reduce the severity of organ damage in the context of SCD. This may inform a strategy of optimizing iron intake as a potential treatment for SCD.

1208

BENEFITS AND COSTS OF HYDROCELE SURGERY IN MALAWI

Eileen Stillwaggon[1], Larry Sawers[2], John Chiphwanya[3], Hannah Betts[4], Sarah Martindale[4], Louise Kelly-Hope[4]

[1]Gettysburg College, Gettysburg, PA, United States, [2]American University, Washington, DC, United States, [3]Ministry of Health, Lilongwe, Malawi, [4]Centre for Neglected Tropical Diseases, Department of Parasitology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Hydrocele, the accumulation of fluid around the testis or testes that expands the volume of the scrotal sac, is the most common manifestation

of lymphatic filariasis, endemic in 72 countries. Hydrocele afflicts about 25 million men in Africa, Asia, Oceania, and the Americas. It is frequently a painful condition that leads to reduced mobility, social withdrawal and exclusion, depression, and reduced work productivity. Some men with hydrocele work fewer days per week or hours per day, may be less productive at work, or simply cannot work. In poor, highly endemic regions, the total earnings loss due to hydrocele perpetuates low income and consumption for the whole community. Surgery provides an effective cure that is safe, inexpensive, and can be performed in field situations. This study measures the economic benefits of hydrocelectomy by estimating the gain in productivity over the patient's lifetime as a result of hydrocele surgery. This benefit-cost analysis is based on pre-operative interviews with 201 hydrocelectomy patients in Malawi who reported their work-time loss due to hydrocele. We calculate the present discounted real (inflation-adjusted) value of the lifetime earnings loss due to hydrocele. In post-operative surveys, respondents reported that surgery almost completely eliminated the disability and earnings loss imposed by hydrocele. We estimate average discounted present value of future earnings gain from hydrocelectomy for all respondents from the present to the end of their working lives to be $614, which is approximately 12 times the cost of the surgery and more than twice the Malawian income per capita in 2016.

1209

DEATHS OF EMERGING AND RE-EMERGING INFECTIOUS DISEASES OUTBREAKS, EPIDEMICS, AND PANDEMICS IN THE LAST 10 YEARS: A SYSTEMATIC REVIEW

Le Huu Nhat Minh[1], Le Khac Linh[2], Hoang Thi Nam Giang[3], Ahmad Zayan[4], Gamal Goda Abdel-Samea Eid[5], Thai Le Ba Nghia[6], Eman Bashir Othman[7], Nguyen Thi Hoai Phuong[8], Tran Thuy Huong Quynh[8], Khalid Muhammad Khalaf[9], **Le Huu-Hoai**[10], Doan Thi Huong[1], Ngo Thi Huyen[1], Nguyen Lam Vuong[1], Masahiro Hashizume[11], Kenji Hirayama[12], Nguyen Tien Huy[13]

The emergence and re-emerge of infectious diseases in the last two decades has heightened concerns about the possibility of global outbreaks of disease and the ability of national and international health systems to respond and to overcome such infections successfully with the least possible number of victims. This study aimed to determine the death of the major emerging and re-emerging infectious disease outbreaks, epidemics, and pandemics during the last 10 years. We searched on 10 following electronic databases: PubMed, Scopus, GHL, VHL, POPLINE, ISI, Google Scholar, SIGLE, NYAM to assess the death of major emerging and re-emerging infectious disease outbreaks from 2006 to 2015. We used NIH tool to assess the risk of bias. The study protocol was registered on PROSPERO, number CRD42016038138. After searching in 10 databases, 8045 studies initially found, 167 were eligible for analysis. Overall case fatality rate is 0.052 (0.044 – 0.062) with 95% CI. The highest overall CFR was at South East Asia Region 13.2% and the lowest was in western Pacific Region 3.5%. The CFR peaked at 2006, 2010 and 2015 (14.9%, 8.6%, and 16%, respectively) with a declination of CFR in-between these years. *Burkholderia pseudomallei* and Nipah virus had the highest CFR (80%, 78.6%) while Enterovirus and Vibrio had the lowest CFR (0.0%, 0.4%). Significant risk of bias found with p-values of (0.0001) using Egger's regression intercept. South East Asia Region had the most death cases of infectious disease outbreaks. *Burkholderia pseudomallei* and Nipah virus were the causative pathogens that caused the highest number of cases of death.

1210

DECIPHERING ETIOLOGIES OF ACUTE FEBRILE ILLNESS IN WEST AFRICA: A JOINT MILITARY - CIVILIAN COLLABORATION

Nkechinyere Elizabeth Harrison[1], Suzanne Mate[2], Johnbull Chuks Mbibi[1], Jeff Koehler[3], Keersten Ricks[3], Jacinta Elemere[1], Blessing Wilson[1], Chibuzo Achugwo[1], Concilia Uzoamaka Agbaim[1], Rosemary O Ndubuisi[1], Olutunde Adegbite[1], Kenneth Ejiofor Oruka[1], Chinonyerem Uzowuru[1], Esther Isaiah[1], Amaka Nzenweokwu[1], Zahra Parker[4], Abiola Fasina[4], Abdulwasiu Bolaji Tiamiyu[4], Edward Akinwale[4], Nurudeen AA Hussain[5], Joseph Diclaro[6], Andrew Letizia[7], Merlin Robb[8], Jessica D. Eisner[8], Nelson Michael[2], Julie Ake[2], Randal Schoepp[3]

[1]68 Nigerian Army Reference Hospital, Yaba, Nigeria, [2]Walter Reed Army Institute of Research, Bethesda, MD, United States, [3]US Army Medical Research Institute of Infectious Diseases, Frederick, MD, United States, [4]Military HIV Research Program Nigeria, (HJFMRI), Yaba, Nigeria, [5]Nigerian Ministry of Defense, Abuja, Nigeria, [6]Navy Entomological Center of Excellence, Jacksonville, FL, United States, [7]Navy Medical Research Unit-3 Ghana Detachment, Accra, Ghana, [8]Henry M. Jackson Foundation, Bethesda, MD, United States

The Joint West Africa Research Group (JWARG) is a global health program facilitating standardization of laboratory methods for disease surveillance in Nigeria, Ghana, and Liberia. Through the protocol "Severe Infectious Disease: Surveillance, Detection, Risks and Consequences in West Africa", it and the U.S. Military HIV Research Program, along with in-country partners, is enrolling military and civilian participants at the 68 Nigerian Army Reference Hospital. In addition to clinical diagnostics, JWARG labs use a MAGPIX multiplex platform and real-time RT-PCR to test for viral hemorrhagic fever and arthropod-borne viruses. To date 43 participants have enrolled. Participants with respiratory symptoms had sputum testing by GeneXpert MTB/RIF to detect of Mycobacterium tuberculosis and Rifampin resistance. HIV testing followed the national testing algorithm and malaria testing at T0 and T28 was performed using BinaxNOW and microscopy. For immunodetection, patient serum was screened with the Luminex MAGPIX platform. Magnetic beads were conjugated with antibodies against Ebola, Marburg, Lassa, and Crimean Congo hemorrhagic fever viruses, Rift Valley fever virus, alphavirus family, and flavivirus family. For molecular detection, real-time PCR utilized virus-specific primers and probes and synthetic RNA controls. Testing so far resulted in 15 HIV positive out of 32 tested. In addition, 11 participants were known to be HIV positive at enrollment. 5 tested malaria positive at T0. Only *Plasmodium faliciprum* was identified on microscopy. 17 participants that tested malaria negative by microscopy were taking antimalarial medications. 11 participants reported contact with animals along with tick, mite, and mosquito exposure. None reporting contact with mosquitoes were malaria positive. Of 11 enrollees tested for MTB, only 3 were positive and no Rifampicin resistance noted. No pathogens were detected by the MAGPIX assay or real-time RT-PCR. The JWARG is developing crucial front line diagnostic and surveillance laboratories in West Africa to discern the prevalence of infectious diseases as well as to improve the ability to respond to outbreaks.

1211

PROGRESS MADE TOWARD THE ELIMINATION OF TRACHOMA AS A PUBLIC HEALTH PROBLEM IN NIGER

Kadri Boubacar[1], Nassirou Baido[1], Adbou Amza[1], Zeinabou T. Koullou[2], Youssouf Yaye[2], Aichatou Alfari[1], Amy Vienoglou[3], Yaobi Zhang[4]

[1]Ministry of Health, Niamey, Niger, [2]Helen Keller International, Niamey, Niger, [3]Helen Keller International, New York, NY, United States, [4]Helen Keller International, Regional Office for Africa, Dakar, Senegal

Trachoma is endemic in 35 out of 42 districts in Niger. The National Eye Health Program (PNSO) began baseline mapping in 1999, with prevalence of trachomatous follicular (TF) as high as 62.3% and 45.7% in health districts (HDs) in Zinder and Maradi region, respectively, and 28.6% in Dosso region. The PNSO plans to eliminate trachoma as a public health problem by 2020 through the WHO-recommended SAFE strategy, operational research, capacity building for PNSO staff, and monitoring and evaluation activities. This strategy involves impact assessments after one, three, five or seven years of mass drug administration (MDA) based on prevalence. Niger started MDA progressively with two HDs in 2002, to which 32 HDs were added between 2004 and 2009 and two additional HDs in 2015, reaching 100% geographic coverage of endemic HDs. Currently, no HD in Niger requires more than three years of treatment. The government reorganized the HDs in Niger from 42 to 72 in 2014. Currently, 10 HDs have a TF prevalence between 5% and 9%; 12 HDs have a prevalence between 10 and 29%; 6 urban and peri-urban HDs are waiting baseline assessment to determine whether they are endemic for trachoma; and 44 HDs are under surveillance (TF <5%). Of the 44 under surveillance, seven HDs have undergone their first surveillance survey, 21 are in progress and 16 are waiting to conduct surveillance surveys. Surveillance surveys conducted in 2017 in Ouallam and Banibangou HDs (Tillaberi region) found a TF prevalence between 5 and 9% and these HDs must conduct an additional year of MDA. The region borders Mali and has been insecure since 2012, experiencing repeated attacks since 2014. It is likely that cross-border migration and internal displacement of populations to refugee camps has contributed to the resurgence of trachoma, which proliferates in areas where water, sanitation and hygiene is poor. To maintain low levels of trachoma in the 16 HDs that have successfully completed their surveillance survey, the PNSO will continue to increase awareness through radio stations.

1212

INFANTILE ANEMIA AND ASSOCIATED MEDICAL CONDITIONS IN GUINEA-BISSAU

David McGregor, Olivia Farrant, Anna Last

London School of Hygiene & Tropical Medicine, London, United Kingdom

Infantile anaemia is a severe public health problem in sub-Saharan Africa and is known to be associated with reduced cognitive development, immune function, and survival. The strength of association between anaemia and common tropical infections is however still poorly understood. Communities of the Bijagos Archipelago in Guinea-Bissau, have an average life expectancy of 55 years and an under 5 mortality of 223 per 1000 live births. Previous research in the archipelago has shown a high prevalence of trachoma, which shares risk factors with soil-transmitted helminths (STH) and *Plasmodium falciparum* infections. The first ever community-based cluster-randomized surveys were conducted in the archipelago to measure the prevalence of anaemia as well as infection with STH and *P. falciparum* during the rainy season between August to October 2017. The findings were analysed to identify the associations between these conditions and help leverage future protective interventions. Estimated hookworm prevalence was found to be 23.23% (95% CI 19-28%; N=419), and estimated malaria parasitaemia was 5.81% (95% CI 3.55-9.36; N=404). 65.35% of participants were estimated to be anaemic by WHO standards (95% CI 61-70%; N= 823). Analysis using a generalised linear model with forward univariate and multivariate logistic regressions showed significant associations between hookworm and *Pf* infection, acute and chronic malnutrition, age groups, sanitation practices and severity of anaemia. The results of these surveys map the links between infantile anaemia and common chronic tropical infections, nutritional status, and sanitation practices. The unique geography of the archipelago is ideally suited for a cluster randomised control trial of biomedical (including mass drug administration and nutrition supplementation), sociological and educational interventions to sustainably disrupt these links.

1213

INITIAL DEATH NOTIFICATION RESULTS FROM THE CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS) SIERRA LEONE PILOT PHASE, OCTOBER 2017 TO FEBRUARY 2018

Mary Claire Worrell[1], Jessica Preslar[2], Sorie I. Kamara[3], Solomon Samura[4], Carrie Jo Cain[4], Baindu Kosia[5], Erick Kaluma[6], Kevin Clarke[1], Amara Jambai[7], Reinhard Kaiser[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]University School of Medicine and Department of Epidemiology, Rollins School of Public Health, Atlanta, GA, United States, [3]eHealth Africa, Makeni, Sierra Leone, [4]World Hope International, Makeni, Sierra Leone, [5]Focus 1000, Makeni, Sierra Leone, [6]eHealth Africa, Freetown, Sierra Leone, [7]Ministry of Health and Sanitation, Freetown, Sierra Leone

The Child Health and Mortality Prevention Surveillance (CHAMPS) Network aims to integrate and share standardized data with key national and global stakeholders on the causes of death in children under-5 and stillbirths. As part of a phased implementation approach, the CHAMPS site in Sierra Leone piloted death notification in three Makeni City Hospitals, two health centers, and two peri-urban communities. From October 2017 to February 2018, the CHAMPS surveillance team received 250 unique death notifications from facility and community reporters. Two-hundred and forty-one of the notified deaths (96%) died at a health facility. Seventy-four of the deaths (30%) were reported as stillbirths. Of the under-5 deaths, 41 (23%) were classified as early neonatal [0 – 6 days], 16 (9%) as late neonatal [7 to 27 days], 62 (35%) as post neonatal deaths [28 days to 1 year], and 54 (31%) children 1-4 years. Eighty-one deaths (34%) were reported with residence in the rural areas of the chiefdom, while 139 (59%) were from the urban areas and 16 (7%) had an unknown residence. To inform planning for advanced diagnostics using minimal invasive tissue sampling (MITS), which must be performed within 24 hours after death, we analyzed time between death and notification. Notification time decreased from a median of 24 hours (interquartile range [IQR] 7 to 58 hours) in October 2017 to 12 hours (IQR 4 to 19 hours) in February 2018. In February 2018, 80% cases were reported within 24 hours of death compared to 48% in October 2017. Although not representative for the CHAMPS site, and mostly from health facilities, pilot data provide initial descriptive information on child and stillbirth mortality, and inform planning for advanced diagnostics starting later in 2018.

1214

PREDICTORS OF LINEAR GROWTH FALTERING IN CHILDREN WITH ENVIRONMENTAL ENTERIC DYSFUNCTION

Najeeha Talat Iqbal[1], Arjumand Rizvi[1], Sana Syed[2], Zehra Jamil[1], shahida Qureshi[1], Tauseef Akhund[1], Najeeb Rahman[1], Fayyaz Umrani[1], Kamran Sadiq[1], Syed Asad Ali[1]

[1]Aga Khan University Karachi, Karachi, Pakistan, [2]University of Virginia, Karachi, Pakistan

Stunting in children under five is enigmatic in the third world countries. A significant proportion (44%) of children have linear growth faltering in Pakistan. A fraction of these children suffer from Environmental Enteric Dysfunction, an acquired syndrome in children with multi-factorial disease processes of environmental insults, inadequate food and repeated infections. These children thought to manifest an underlying

inflammatory condition of the small intestine that translates into linear growth faltering. The objective of our study is to assess the association of co-morbids and biomarkers on growth outcome from birth to 18 month. In a rural setting of Pakistan, we prospectively enrolled a birth cohort and followed up to 18m for monthly anthropometric measurements. Blood and fecal samples were collected at 6 and 9 ms. In a linear Mixed Effects Model, the outcome of change in LAZ (length for age Z score) at 18m was independently analyzed for various exposures, stunted at birth, co-morbid and levels of systemic and gut inflammatory bio-markers. Principal Component Analysis (PCA) was applied to reduce the bio-markers (n=23) in to 5 main components. Mixed model used child as a random effect and PCAs of bio-markers, stunted at enrollment ,low birth weight, gestational age <37 wks, fever, diarrhea, cough and chest in drawing as fixed effect. Adjusted analysis showed stunted at enrollment (β: -1.06 ; 95%CI: -1.26,-0.86) , low birth weight (β: -0.36 ; 95% CI : -0.56,-0.16), gestational age <37wks (β: -0.45 ; 95% CI: -0.63,-0.26), PCA2 at 9 month (Ferritin, C-reactive protein, Insulin like Growth Factor and α1-Acid Glycoprotein) (β: -0.12; 95% CI : -0.21,-0.03) and PCA5 at 9 month (fecal Myeloperoxidase and Regenerating Protein-1β) (β: -0.09; 95% CI -0.18,0.00) were associated with significant change in LAZ from birth to 18m. Our data suggests that low birth weight or stunted at birth are major determinants of linear growth faltering independent of diarrhea and acute respiratory illnesses. Of 23 bio-markers, systemic inflammatory bio-markers were predominantly involved in linear change in LAZ, most likely through the pathway of gut inflammation.

DESIGNING A NOVEL MULTIPLEX MULTI-ANALYTE DIAGNOSTIC PLATFORM (MAPDX) TO ADDRESS SEVERE FEBRILE ILLNESS

Jennifer Osborn[1], Teri Roberts[2], Maurine Murtagh[1], Cassandra Kelly-Cirino[1], Sabine Dittrich[1], Oscar Bernal[3], Francis Moussy[4], Ethan Guillen[3]

[1]Foundation for Innovative New Diagnostics (FIND), Geneva, Switzerland, [2]MSF Access Campaign, Geneva, Switzerland, [3]Doctors Without Borders, New York, NY, United States, [4]World Health Organization, Geneva, Switzerland

Despite advancements in multiplex diagnostics in high-income countries, multiplex testing is rarely available in low-resource settings (LRS). A limited test menu hinders clinical decision-making and antimicrobial stewardship, leading to empiric treatment and suboptimal patient outcomes. This is particularly true for management of severe febrile illness without a known source (SFWS), since many pathogens present with similar symptomology. To revolutionize multiplex capabilites in LRS, Médecins Sans Frontières (MSF) partnered with FIND to examine the feasibility of developing a new diagnostic for near-patient testing of several pathogens and different analyte types called MAPDx. Together with the World Health Organization (WHO), a target product profile (TPP) was drafted to inform developers of minimal and optimal system requirements. Utilizing a Delphi process, 60 stakeholders (industry, experts, and end-users) reviewed the TPP through two survey rounds, an online public consultation, and an in-person consensus meeting. The final TPP contains 41 characteristics describing the envisioned MAPDx intended for management of patients with SFWS in a district hospital setting, but ideally for diagnosis of other diseases. The instrument must be capable of simultaneous detection of different analytes types (e.g., nucleic acids and serological markers) in either an integrated assay cartridge (optimal) or dedicated cartridges for each analyte type (minimal) to identify at least 6 targets, and ideally > 15 targets from a single specimen. The assay cartridge must contain all reagents, require little to no sample pre-processing, and meet 'semi-open' design specifications so that multiple assay developers can make a variety of tests for use on the platform. MAPDx must be robust to environmental conditions such as dust, temperature extremes and high humidity, while maintaining an affordable price (optimally < USD 5,000 / instrument and < USD 5 / cartridge). In summary, this rigorous TPP process resulted in an ambitious but attainable vision of MAPDx. If realized, this innovation would be a transformative advancement for diagnostics in LRS.

BRAIN MRI IN IMPORTED MALARIA

Thierry Rolling, Michael Schoenfeld, Thomas T. Brehm, Christof D. Vinnemeier, Marylyn M. Addo, Jens Fiehler, Andreas M. Frölich

University Medical Centre Hamburg-Eppendorf, Hamburg, Germany

Previous studies have documented a spectrum of brain MRI abnormalities in patients with cerebral malaria, but less is known about findings in patients with non-cerebral malaria. Inpatients at the University Medical Centre Hamburg-Eppendorf (Germany) with microscopically confirmed *Plasmodium falciparum* malaria could participate in this study. Brain MRI was acquired preferentially in the first 24 hours after admission using a 3T Magnetom Skyra (Siemens, Erlangen, Germany). Brain MRI was independently assessed for structural lesions by two radiologists blinded to clinical information. A total of 17 patients underwent MRI and were included in the analysis. Half (n=8) were immigrants from malaria-endemic countries who were visiting friends and relatives (VFR), while the other half were non-immune travellers. Patients' age ranged between 20 and 64 years. Severity of malaria ranged from mild (with few clinical symptoms and less than 0.1% of infected erythrocytes) to severe (with neurological involvement and very high parasitaemia of 40% of infected erythrocytes). Five patients were classified as complicated malaria according to WHO criteria. Four patients had reduced vigilance and/or confusion (Glasgow Coma Scale scores between 12 and 14). No focal neurological deficits were noted in any of the included patients. Structural brain abnormalities detected included a hyperintense lesion of the splenium on T2-weighted imaging (n=3), accompanied by visible diffusion restriction in two cases. An isolated single brain microhemorrhage was detected in 3 patients. Small focal T2-hyperintense signal abnormalities of the deep and periventricular white matter were frequent findings, ranging from absent to diffuse. We did not observe significant correlations between parasitemia and the apparent diffusion coefficient in any of the locations (p>0,05). In conclusion, we describe a considerable frequency of T2-hyperintense splenial lesions in returning travellers with malaria, which appears to be independent of the degree of parasitemia. Future studies may reveal whether an immunologic or therapy-related etiologiy could explain this phenomenon.

1217

A CASE OF INITIALLY UNEXPLAINED CARDIOMYOPATHY AND THE ROLE AND OPERATING CHARACTERISTICS OF REMOTE TELECONSULTATION

Steven Fox[1], Erin Kim[2], Michelle Turner[2], Meghan Moretti[2], Timothy Girard[1], Stephen Y. Chan[2]

[1]University of Pittsburgh Medical Center, Pittsburgh, PA, United States, [2]The Addis Clinic, Jamaica Plain, MA, United States

Dilated cardiomyopathies are prevalent worldwide; however, etiology often remains unexplained, making it difficult to diagnose without specialized care. Here, we describe a clinical presentation of endomyocardial fibrosis, a relatively common but underrecognized cause of cardiomyopathy in tropical regions, and describe the role of asynchronous remote teleconsultation in increasing capacity to interpret echocardiograms. We present a 50 year old Guyanese man who was admitted to an urban referral hospital with several weeks of progressive shortness of breath, cough, and several days of altered mental status. The clinical assessment was concerning for heart failure, so bedside echocardiography was performed, which revealed a dilated cardiomyopathy of unclear etiology. The case summary along with echocardiography clips were sent for review to a cardiology team via an asynchronous teleconsultation organization, The Addis Clinic, and the diagnosis of endomyocardial fibrosis was made. In this case, teleconsultation was key in determining diagnosis, prognosis,

and management plan. We review operational aspects of teleconsultation, including patient selection, development of referral templates, steps in allocation, and response to the referrer. We see that asynchronous teleconsultation is most effective for cases that are less acute, less common, and require more specialized knowledge to diagnose, such as this case. Inclusion of photos, or in this case, echocardiographic clips, can be an important component of the consultation. Turn-around-times of 24-48 hours can be achieved in an asynchronous telemedicine network, but requires very short turn-around-times of individual steps in the referral. In summary, we describe a case of endomyocardial fibrosis, a relatively common but less well recognized cause of cardiomyopathy. Through this case and through review of operational aspects of teleconsultations, we illustrate how telemedicine can play a role in diagnosis, prognosis, and management of tropical medicine conditions, particularly those that are chronic and require specialized skills to diagnose or manage.

1218

METABOLOMIC ASSOCIATIONS WITH STUNTING IN EARLY CHILDHOOD IN A BANGLADESHI COHORT

Girija Ramakrishnan

University of Virginia, Charlottesville, VA, United States

Malnutrition is a challenging global health problem affecting almost one in four children under age 5. It significantly impacts survival in early childhood, leads to growth stunting, and has long-term negative consequences on neurocognitive development and performance. Data compiled from a comprehensive longitudinal study of a birth cohort of children in an urban slum in Bangladesh (PROVIDE) indicated that stunting was associated with environmental enteropathy, systemic inflammation and maternal malnutrition. However, there remains a gap in knowledge of biological factors driving stunting, and better understanding of metabolic associations with disease would aid in devising effective interventions to limit its effects. In a pilot study to investigate potential metabolic alterations associated with stunting, we conducted targeted metabolomics on plasma from 25 stunted children (HAZ<2) and 25 non-stunted controls in the PROVIDE cohort. Plasma was analyzed at 10 months and 1 year of age, and stunting assessed at age 2. The 34 metabolites, chosen on the basis of previous metabolic modeling studies, included amino acids, short chain fatty acids (SCFA) and tricarboxylic acid (TCA) cycle intermediates. Differences in metabolites between stunted and non-stunted groups were analyzed using a Mann-Whitney test and a critical value of 0.0121 calculated using the Benjamini-Yekutieli False Discovery Rate procedure. Stunted children were found to have significantly lower levels of tryptophan both at 10 months (p=0.0095) and at 1 year (p=0.0013). Tryptophan is a precursor for synthesis of a wide range of metabolites impacting growth, immune modulation and neurodevelopment, and our results suggest that limitation may contribute to the development of environmental enteropathy or stunting. Stunted children also had reduced levels of arginine at 10 months (p=0.0004) and threonine at 1 year (p= 0.0010). Efforts are ongoing to validate these findings in a larger cohort, and to explore their biological relevance. Further investigation of metabolite profiles could potentially identify early biomarkers for stunting or targets for intervention.

1219

CHAGAS DISEASE SEROLOGY AND CO-INFECTIONS WITH ARBOVIRUSES IN SOUTHERN COASTAL ECUADOR

Neida K. Mita Mendoza[1], Elizabeth McMahon[1], Aileen Kenneson[1], Arturo Barbachano-Guerrero[2], Efrain Beltran-Ayala[3], Cinthya Cueva[1], Christine A. King[2], Christine D. Lupone[1], Yagahira E. Castro-Sesquen[4], Robert H. Gilman[4], Timothy P. Endy[5], Anna M. Stewart-Ibarra[5]

[1]Center for Global Health and Translational Science, SUNY Upstate Medical University, Syracuse, NY, United States, [2]Department of Microbiology and Immunology, SUNY Upstate Medical University, Syracuse, NY, United States, [3]Department of Medicine, Universidad Tecnica de Machala, Machala, Ecuador, [4]Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [5]Department of Medicine, SUNY Upstate Medical University, Syracuse, NY, United States

Chagas disease and arboviral infections are neglected vector borne diseases co-endemic throughout the Americas, but co-infection rates and immunological implications are largely unknown. This study examined the proportion of individuals positive for Chagas disease and co-infections with dengue (DENV), chikungunya (CHIKV), and Zika viruses (ZIKV) in an ongoing arbovirus surveillance study in Machala, Ecuador. We also evaluated five serological tests for Chagas disease. Samples were collected from individuals between January 2014 - December 2015. Serological positivity for Chagas disease was evaluated by three commercially available enzyme-linked immunosorbent assays (ELISAs), and a western blot assay (TESA blot). Chagas disease seropositivity was defined by agreement in at least two conventional tests. Additionally, the rapid test Chagas Detect Plus (CDP), was also evaluated. DENV infections were identified by NS1 rapid test, NS1 ELISA, IgM ELISA and RT-PCR, and acute CHIKV and ZIKV infections by RT-PCR. We found that 6/658 individuals (0.9%) were positive for *T. cruzi*. The average age for *T. cruzi* positive individuals was 63 years and 67% were female. We found one individual with *T. cruzi*/DENV co-infection and another with *T. cruzi*/CHIKV/DENV co-infection (0.1%), corresponding to an acute secondary and a primary DENV infection, respectively. Chagas serology test performance was as expected in all tests, however, we observed discrepancies by the Hemagen Chagas Kit and the rapid test CDP, with false positive percentages of 3.9% (1/26) and 15.4% (4/26), respectively. This preliminary finding suggests further test validation of the InBios rapid test CDP is needed in other endemic areas. This study revealed a low proportion of Chagas and DENV/CHIKV co-infections in Machala, and provides the first evidence of *T. cruzi*/arbovirus co-infections in the area to our knowledge. Future studies should rigorously investigate *T. cruzi*/arbovirus co-infection prevalence, and potential disease severity co-modulation effects to guide intervention strategies in high-risk populations.

1220

CULTURE ISOLATION AND GEOGRAPHICAL DISTRIBUTION OF *LEPTOSPIRA* SPP FROM PATIENTS WITH LEPTOSPIROSIS IN SRI LANKA

Dinesha D. Jayasundara[1], Indika S. Senevirathna[1], Janith N. Warnasekara[1], Chandika D. Gamage[2], Michael Matthias[3], Joseph M. Vinetz[3], Suneth B. Agampodi[1]

[1]Faculty of Medicine and Allied Sciences, Anuradhapura, Sri Lanka, [2]Faculty of Medicine, Peradeniya, Sri Lanka, [3]Department of Medicine, San Diego, CA, United States

The most recent culture isolation and serotyping of *Leptospira* spp. in Sri Lanka was reported in 1973, although the country is globally considered as a hot spot for leptospirosis. Changes in circulating *Leptospira* spp since 1960s is lacking. This knowledge gap hinders preventive and control measures. We carried out a multi centre hospital based study since June 2016 to fill this knowledge gap. Patients presenting with acute undifferentiated fever to six hospitals located in different geographical regions including wet and dry zones were included as the study population. Two to four drops of venous blood was collected on admission from each patient and bed side inoculation was done into EMJH semi solid media. Samples were subsequently incubated at 30^0C. Initial inspection of the samples was done after three weeks and on monthly basis thereafter. Positive samples were sub cultured in to liquid media and an aliquot was saved in -80^0C. Total of 728 cultures were collected over a period of 18 months and *Leptospira* spp were isolated from eighteen (2.5%) samples from five districts. Out of the 18 isolates 3 had a short incubation period of three weeks while others took longer to show positivity.To determine the species, a validated multi-gene targeted qPCR was done using four primer pairs. These were specifically designed to differentiate *L.interrogans,*

L.kirschneri, L.noguchi and L.borgpetersenii. All eighteen samples were subjected to this assay. Fourteen isolates were turned out to belong to *L.interrogans* and three were *L.borgpetersenii.* One isolate didn't belong to any of the species tested. In this study, we culture isolated *Leptospira* spp for the first time from the dry zone in Sri Lanka. *L.interrogans* was isolated from both dry and wet zones whereas *L.borgpetersenii* isolates show space and time clustering which were only found in the dry zone in three consecutive patients admitted to the ward within a month period. Our ongoing studies on whole genome sequencing of these isolates will enable to enhance the current knowledge on leptospirosis pathogenesis and will help in establishing possible reservoir hosts to facilitate preventive and control measures.

1221

DIARRHEA HOME MANAGEMENT AND DEHYDRATION IDENTIFICATION IN BAMAKO, MALI: PARENTS OF CHILDREN UNDER-5 LACK KNOWLEDGE AND CONFIDENCE

Elizabeth Dupont[1], Lamine Mariko[2], Fatoumata Sogodogo[2], Modibo Keita[2], Anna Roose[3], Ballan Sangare[2], Doh Sanogo[2], Kounandji Diarra[2], Rokia Dembele[2], Uma Onwuchekwa[2], Adama Mamby Keita[2], Elie Schoenbaum[1], Juan Lin[1], Milagritos Tapia[3], Samba Sow[2], Karen Kotloff[3]

[1]Albert Einstein College of Medicine, Bronx, NY, United States, [2]Center for Vaccine Development- Bamako, Bamako, Mali, [3]Center for Vaccine Development- University of Maryland Baltimore, Baltimore, MD, United States

Diarrhea is among the top five causes of child mortality globally. The Integrated Management of Childhood Illness (IMCI) guidelines for management of Acute Watery Diarrhea (AWD) contains evidence-based recommendations for improving outcome of diarrheal illnesses, but research demonstrates incomplete adherence in Mali. Greater understanding of parental knowledge and attitudes about management may lead to more effective messaging for adherence. Using stratified random sampling of children under-5, we interviewed 30 mothers in a censused population of Bamako, Mali. Stratification was by age, gender, and neighborhood. Interviews used diarrhea-related scenarios to assess syndrome recognition, perceived cause, and factors that influence care-seeking. Wilcoxon two-sample and Fischer's exact tests assessed associations between categorical variables from interviews and parental preference for seeking care from the informal or formal sector (formal sector includes professionals held to IMCI guidelines: physicians and pharmacists). Our data show Malian parents believe that 1) diarrhea is part of normal child development, 2) the need to increase fluids and continue feeding for children with AWD is under-appreciated, and 3) most parents cannot identify 2 signs of severe dehydration that should prompt care-seeking from the formal sector. Perceived quality of provider treatments, age >1 year, and low confidence in home management were associated with preference for the formal sector. Demographic factors and perceived syndrome cause were not significantly associated with sector preference. Strategic efforts to promote cultural shift in care-seeking behaviors for AWD could improve rates of morbidity and mortality attributed to childhood diarrhea in Mali. Parent education should focus on 1) the dangers of untreated diarrhea for children, 2) increased fluids and continued feeding at home, and 3) symptoms of dehydration that should prompt formal sector consultation. Collaboration with communities and providers from both sectors are desirable to develop consistent messaging about evidence-based home management and care-seeking.

1222

FROM INFECTION TO DISEASE IN LOIASIS: A SYSTEMATIC REVIEW OF CLINICO-EPIDEMIOLOGICAL CASE REPORTS

Kevin G. Buell[1], Charles Whittaker[1], Cédric B. Chesnais[2], Paul Jewell[1], Sébastien D. Pion[2], Maria-Gloria Basáñez[1], Michel Boussinesq[2]

[1]Imperial College London, London, United Kingdom, [2]Institut de Recherche pour le Développement (IRD), Montpellier, France

Loiasis, a filarial infection caused by *Loa loa*, is a neglected tropical disease (NTD) estimated to affect over 10 million people in heavily forested countries of central Africa. Calabar swellings (transient migratory subcutaneous swellings) and eye worm passages are the hallmarks of the disease. It was previously considered benign and solely viewed as a public health impediment to mass ivermectin administration for onchocerciasis and lymphatic filariasis. Challenging this conception, a recently published cohort study conducted in Cameroon demonstrated increased mortality in those with high *Loa loa* microfilaraemia. Furthermore, case reports on atypical cardiac, respiratory, gastrointestinal, renal, and neurological clinical manifestations are becoming increasingly prevalent in the scientific literature. We undertook a systematic review of all published case reports containing individual-patient data on loiasis. The aim was to determine the full spectrum of clinical manifestations and assess whether these can be correlated to infection severity and/or markers of infection. We also wanted to quantify worm longevity from data on the interval between last exposure and presenting with signs of active infection. Information on patient demographics, co-infection with other parasites, typical and atypical symptoms, serum biochemistry, microfilaraemia, clinical imaging, pharmacological management and patient outcomes were collected. This study is the largest systematic review of individual-patient data on loiasis, tripling in number of patients, its closest comparable predecessor published in 2005. Results suggest that the atypical presentations cause significant patient morbidity and confirm previous findings that patient demographics play a role in determining clinical presentation and markers of infection. This project is part of a wider undertaking to develop a model for the global disease burden due to loiasis. It will serve as a foundation towards estimating the true morbidity associated with loiasis and will help to support the argument that loiasis should be included on the World Health Organization NTD list.

1223

NEUTRALIZING ANTIBODY AFTER 2 INTRADERMAL DOSES PRE-EXPOSURE PROPHYLAXIS OF PURIFIED VERO CELL RABIES VACCINE (PVRV) TO 12 TO 24 MONTH-OLD CHILDREN, CONCOMITANTLY WITH JAPANESE ENCEPHALITIS CHIMERIC VIRUS VACCINE (JE-CV)

Piyada Angsuwatcharakon

Queen Saovabha Memorial Institute (WHO Collaborating Center for Research on Rabies Pathogenesis), Bangkok, Thailand

Rabies Pre-exposure prophylaxis is recommended for children living in endemic area. Our institute had studied the 2-site i.d. PrEP on day 0 and 21 with 0.1 ml of PVRV in adults and found this regimen effective, safe and cost saving compared to the usual 3-doses i.m. regimen. In Thailand it is mandatory to children aged 9-12 months to receive JE vaccine according to national immunization program and boost 1 year later. We studied the immunogenicity and safety of two-visit i.d. regimen compared with conventional i.m. regimen when co-administered with a live attenuated JE chimeric virus vaccine (JE-CV) in 9-18 months old children to improve further the acceptability of childhood rabies immunization. The trial was controlled, randomized 2:1, open-labelled. Forty-nine seronegative healthy Thai children were allocated to Group A (n=32) given 0.1 ml of PVRV i.d. at two sites on day 0, 28 and Group B (n=17) given 0.5 ml of PVRV i.m. on day 0, 7, 28. Both groups received JE-CV subcutaneously on day 0 (concomitantly with rabies vaccine day 0) and 365. Rabies virus

neutralizing antibody (RVNA) titers were measured on days 0, 42 and 365. JE neutralizing antibody titers were determined on day 0, 365 and 379 (14 days after JE-CV booster vaccination). All subjects had RVNA titers ≥ 0.5 IU/ml (protective level) on day 42 after PrEP vaccination, the geometric mean titers (GMTs) of RVNA titers in group A and B were 14.35 IU/mL (range 2.10 - 43.62 IU/mL) and 14.83 IU/mL (range 5.68 - 41.77 IU/mL), respectively. The GMTs of RVNA for group A and B on day 365 were 1.49 IU/mL (range 0.15-6.16 IU/mL) and 2.00 IU/mL (range 0.47-4.96 IU/mL), respectively. There was no statistically significant difference between GMTs of RVNA titers for group A and B on day 42 and 365. All subjects were seroprotected after receiving the JE-CV primary and booster dose one year later. Mild local adverse events e.g. injection site pain, pruritus, erythema and fever were observed. In conclusion, there was no evidence for any interference between rabies vaccine and JE vaccine, supportive that 2-site i.d. PrEP regimen on day 0 and 28 with 0.1 ml of PVRV and JE-CV are safe and immunogenic when co-administered.

1224

SPLENOMEGALY WITH A SIDE OF SINISTER PORTAL HYPERTENSION

Abdelghani El Rafei, Ann Settgast

Department of Internal Medicine, University of Minnesota, Minneapolis, MN, United States

Introduction: Splenomegaly is increasingly identified among refugees resettling in the United States. In one study 15% of screened Congolese refugees had splenomegaly. In the absence of prior diagnosis the etiology can be difficult to determine. Case Presentation: A 33 year old male refugee from DRC with PMH significant for appendectomy presented to primary care clinic three weeks after arrival to the U.S. with episodic chest tightness, and fatigue for at least 6 months. On exam patient had normal vitals, splenomegaly, and caput medusa. Labs were pertinent for leukopenia (WBC 1.7 k/ul), thrombocytopenia (Pct 52 k/ul), normal Alt (14 u/l), Ast (25 u/l), elevated T. bilirubin (1.7 mg/dl) with (0.6 mg/dl) D. bilirubin. Patient had normal albumin (4.1 g/dl) and mildly elevated INR (1.3). Hepatitis serologies were negative for acute/chronic HBV or HCV and showed immunity to HAV. Abdominal US with Doppler showed enlarged spleen measuring (16.4 cm) and no evidence of portal or hepatic vein thrombosis. O&P testing x3 and schistosoma mansoni serology were negative. Patient was referred to Gastroenterology for further evaluation. EGD showed large >5 mm esophageal varices that were banded. Liver biopsy showed normal liver parenchyma with no evidence of cirrhosis and no infectious organisms. Hepatic pressure measurements showed Hepatic venous pressure gradient pressure of 1 mmhg which is not consistent with portal hypertension (PHTN). CT abdomen/pelvis was obtained, and is pending at this time. Other pending studies include serum sample that will be sent to CDC for repeat Schistosoma testing and malaria PCR testing. Discussion: Our patient had normal liver biopsy and intrahepatic pressures despite having clinical PHTN. Left sided PHTN is a rare clinical syndrome and accounts for less than 5% of all cases of PHTN. It occurs as a result of isolated splenic vein pathology. Patients with this syndrome have a normal liver biopsy and hepatic pressures. Differential diagnoses include spleen infiltrative disease (hyperreactive malaria hypersplenism syndrome, lymphoma, TB), pancreatic disease or schistosomiasis with falsely negative serology.

1225

PRIORITIZING PATHOGENS TO SUPPORT DIAGNOSTIC PRODUCT DEVELOPMENT FOR FEBRILE ILLNESS MANAGEMENT: A NOVEL YET PRAGMATIC APPROACH

Paul Roddy[1], Jennifer Osborn[2], Teri Roberts[3], Ethan Guillen[1], Oscar Bernal[1], Stefano Ongarello[2], Armand Sprecher[4], Ann-Laure Page[5], Isabela Ribeiro[6], Erwan Piriou[7], Abiy Tamrat[8], Roberto de la Tour[8], Bhargavi Rao[9], Laurence Flevaud[10], Tomas Jensen[1], Lachlan McIver[3], Cassandra Kelly[2], **Sabine Dittrich**[2]

[1]Médecins Sans Frontières (MSF), New York, NY, United States, [2]Foundation for Innovative New Diagnostics (FIND), Geneva, Switzerland, [3]Access Campaign, Médecins Sans Frontières, Geneva, Switzerland, [4]Médecins Sans Frontières (MSF), Brussels, Belgium, [5]Epicentre, Paris, France, [6]Drugs for Neglected Diseases initiative (DNDi), Geneva, Switzerland, [7]Médecins Sans Frontières (MSF), Amsterdam, Netherlands, [8]Médecins Sans Frontières (MSF), Geneva, Switzerland, [9]Médecins Sans Frontières (MSF)-Manson Unit, London, United Kingdom, [10]Médecins Sans Frontières (MSF), Barcelona, Spain

Febrile illness is a frequent reason for admission to hospital in low-resource settings (LRS). Management of patients with severe febrile illness without a known source (SFWS) is a challenge for clinicians and diagnostic developers due to numerous reasons. In LRS, diagnostic capacity, including at the hospital, is limited and empiric treatment is commonplace; resulting in suboptimal patient outcomes and antimicrobial resistance. MSF partnered with FIND to examine the feasibility of developing a novel diagnostic capable of simultaneous testing for multiple pathogens and analyte types, to improve management of SFWS. As a part of this endeavor, a list of priority pathogens was developed to allow more targeted treatment and advance surveillance capacity. Herein, we describe our pragmatic approach, combining peer-reviewed data overlaid with expert knowledge and experience to identify a list of priority pathogens. This two-pronged quantitative/ qualitative approach aimed to address the lack of comprehensive etiology data and allow for continuous improvement when new data become available. As per earlier prioritization by health institutions, e.g. WHO, an analytical hierarchy process (AHP) was applied to a pre-defined list of pathogens selected from Prasad *et al.*'s (2015). The AHP was made up of 5 categories (annual cases, severity, morbidity, patient impact, and public health impact). Weights were assigned to each category based on a pairwise comparison performed by nine experts (MSF, DNDi). This data derived list was subsequently subjected to the input of the wider scientific community via an online survey (n~100) to re-define and re-rank pathogens based on expert opinion with evidence-based justification. The resulting list of priority pathogens will inform a target product profile for a SFWS multi-analyte and multi-pathogen assay universal across geographical regions/ patient groups. This represents a unique and pragmatic approach to define global health priorities in diagnostics and an opportunity to catalyze research and development efforts in this important area of public health need.

1226

FREQUENCY AND ASSOCIATED FACTORS OF TYPHOID CARRIER ON DUODENAL FLUID CULTURE IN A TERTIARY CARE HOSPITAL, KARACHI

Sonia Qureshi, Farah Naz Qamar, Tahir Yousafzai, Shafquat Rozi, Shahida Qureshi, Aneeta Hotwani, Kamran Sadiq, Om Prakash

Aga Khan University Hospital, Karachi, Pakistan

Typhoid fever is a serious public health problem and remains a major cause of morbidity and mortality worldwide. Typhoid carriers serve as a reservoir in the ongoing transmission of typhoid fever. This study aims to determine the frequency of typhoid carriers in a typhoid endemic country by performing duodenal fluid culture in patients undergoing upper gastrointestinal (GI) endoscopy. We conducted a crossectional study at Aga

Khan University Hospital, Karachi from February-August 2017. Individuals of age ≥1 year who underwent upper GI endoscopy for any reason were included. Duodenal fluid culture was performed for identification of *Salmonella. typhi* and *paratyphi*. Statistical analysis carried out using Stata. For socioeconomic status factor analysis was performed. Overcrowding was assessed by estimating crowding index. GIS mapping was done for visualizing distribution of study participants. Out of 801 participants, 477 were enrolled. The mean±SD age (years) of the individuals was 42.4±15.5. Majority 287/477 (60.2%) were males. Two thirds (74.5%) of the Participants were from the province of Sindh (54% from Karachi), 13.6%, 3.4% and 3.4% from Baluchistan, Punjab and KPK respectively. 205/477(42.9%) reported use of unsafe water for drinking in their homes. 389/477 (81.5%) underwent upper gastrointestinal endoscopy for the diagnosis of gastrointestinal illness. 73(15.3%) reported past history of typhoid fever. Only 9/477 (1.9%) stated that they had received antibiotics in last two weeks of the procedure. Out of 477 cultures, 250 (52.4%) were positive for a bacterial isolate. None of the cultures showed growth of *salmonella. typhi* or *paratyphi* . However, common pathogens isolated were *Escherichia coli* 68 (27.2%) followed by *Pseudomonas species* 58(23.6%), *Klebsiella pneumonia* 35 (14%). We were not able to identify any typhoid carrier on duodenal fluid culture among subjects undergoing upper GI endoscopy. Carrier detection remains one of the best ways to stop transmission of salmonella. We propose molecular detection methods to determine the prevalence of carrier state after an episode of typhoid.

1227

UNUSUAL DEATHS IN TWO HEALTH DISTRICTS IN THE EAST REGION-CAMEROON: A CASE CONTROL STUDY, 2016

Natacha Marilyne Nsiewe[1], Chanceline Bilounga Ndongo[1], Paul Adrien Atangana[2], Aggée Ntonga[1], Franck Amabo[1], Eric Mboke[1], Elise Seukap[1], Joelle Nwanko[1], George Alain Etoundi[1]

[1]Ministry of Public Health, Yaoundé, Cameroon, [2]Centre Pasteur du Cameroun, Yaoundé, Cameroon

In November 2016, the Districts of Abong-Mbang and Doumé Cameroon, reported 22 unexpected deaths clustered in 3 areas. All cases had a common history of sight loss, headaches and/or coma leading to death following the consumption of locally manufactured alcohol ("odontol"). A multidisciplinary team investigated the event and conducted a case control study. An active case finding took place in community and health facilities. A case was any person who suddenly died or complained of one or more of the following signs and symptoms: headaches, tiredness, nausea, drowsiness, coma, partial or total sight lost from the 8th -15th November 2016 in Abong-Mbang and Doumé Health Districts. Controls were persons in the neighborhood of cases who were not ill. The ratio of 1 case for 2 controls was adopted. Data was collected using a standardized questionnaire including sociodemographic characteristics, date of onset, sign and symptoms. In addition, blood, urine and post mortem gastric and hepatic samples were collected for analysis. Logistic regression was used for analyses. A total of 83 cases were identified, 53 women (64%); the median age was 40 years (range 20-60 years) with 27 deaths (CRF=33%). Symptoms included asthenia 74% (n=60), visual impairment 68% (n=56) and blindness 16% (n=13). Local alcohol was identified as a risk factor (OR=11, IC 95% 5.8-21). Thirty two blood and urines sample were collected and 2 post mortem gastric and hepatic samples taken. Methanol and formate were found in 33% (n=11) blood samples with concentrations up to 510mg/l (norm 5mg/l); and in 19% (n=6) urine samples up to 380 mg/l (norm <2mg/l). Toxicological analysis revealed 1.25 mg/l of methanol and 837 mg/l of formate in post mortem samples. The unusual deaths were due to methanol intoxication. Administrative measures must be taken for a better quality control of alcoholic beverages.

1228

CLINICAL RECOGNITION AND MANAGEMENT OF DRUG-DRUG INTERACTIONS IN A RURAL TANZANIAN HIV COHORT

Andrea Kuemmerle[1], George Sikalengo[2], Fiona Vanobberghen[1], Robert C. Ndege[2], Gideon Foe[3], Chloe Schlaeppi[4], Tracy R. Glass[1], Maja Weisser[5], Catia Marzolini[5]

[1]Swiss Tropical and Public Health Institute, Basel, Switzerland, [2]Ifakara Health Institute, Ifakara, United Republic of Tanzania, [3]San Francis Referral Hospital, Ifakara, United Republic of Tanzania, [4]University of Basel, Basel, Switzerland, [5]University Hospital Basel, Basel, Switzerland

Increasing numbers of people living with HIV have access to antiretrovirals (ARV) resulting in significant prolongation of life with more age-related co-morbidities and consequently greater use of co-medications. Polypharmacy increases the risk of drug-drug interactions (DDI) which can lead to clinical toxicity or treatment failure. To date, potentially clinically relevant DDIs (PCR-DDI) have mainly been analyzed retrospectively using cohort data, therefore not providing information on clinical recognition of PCR-DDIs nor whether management was appropriate, e.g. switch to a non-interacting drug, dosage adjustment, or close clinical monitoring. This study aims to prospectively assess the recognition and management of PCR-DDIs by clinicians of the Chronic Diseases Clinic of Ifakara and patients included in the Kilombero and Ulanga Antiretroviral Cohort (KIULARCO), Ifakara, Tanzania. Information on demographics, clinical parameters, co-morbidities, prescription of ARVs and co-medications, treatment adherence, and laboratory monitoring are systematically captured during visits in an electronic patient chart. For the purpose of this study, an additional paper form was used to collect information on the recognition and management of PCR-DDIs. From 17 March to 13 July 2017, 378 paper forms were filled in for all consenting patients on ARVs and at least one co-medication. DDIs will be screened using the Liverpool Interaction tables (www.hiv-druginteraction.org) and categorized as deleterious (red), of potential clinical relevance (amber), or of weak clinical significance (yellow). The recognition and management of PCR-DDIs will be evaluated in a standard way using a defined algorithm including following criteria: DDI recognized by clinician (yes/no), planned appropriate management (yes/no), application of management plan (yes/no due to operational issues). This study will generate evidence for the first time on the recognition and management of PCR-DDIs in HIV-infected persons in rural Africa, leading to recommendations on how to minimize PCR-DDIs such as by consolidating education or improving operational issues.

1229

REDUCED INPATIENT MORTALITY IN UGANDAN CHILDREN WITH SEVERE ANEMIA DIAGNOSED AND MANAGED ACCORDING TO CLINICAL GUIDELINES COMPARED TO THOSE NOT MANAGED ACCORDING TO GUIDELINES

Robert O. Opoka[1], William Oyang[2], Harriet Nambuya[3], Chandy C. John[4], James K. Tumwine[1], Charles Karamagi[1]

[1]Makerere University, Kampala, Uganda, [2]Lira Regional Referral Hospital, Lira, Uganda, [3]Jinja Regional Referral Hospital, Jinja, Uganda, [4]Ryan White Center for Pediatric Infectious Disease and Global Health, Indiana University School of Medicine, Indianapolis, IN, United States

In resource limited settings, adherence to clinical guidelines in the management of children presenting to hospitals with common clinical conditions like severe anemia (SA) varies markedly. However, there is limited data on how adherence to clinical guidelines affects inpatient outcomes. Inpatient records of 1,131 children aged 0 to 5 years assigned a clinical diagnosis of 'severe anemia (SA)' in two regional referral hospitals in Uganda, were retrospectively reviewed to determine whether or not they were diagnosed and managed according to clinical guidelines. The rate of in-patient deaths were then compared for SA patients diagnosed and managed according to clinical guidelines to those not diagnosed and managed according to these guidelines.Logistic regression analysis was

conducted to evaluate the relationship between clinical care factors and inpatient deaths amongst patients managed for SA. Children diagnosed and managed according to clinical guidelines were less likely to die during hospitalization compared to those managed inappropriately (10/376 (2.7%) vs. 67/755 (8.9%), $p< 0.001$). Factors associated with decreased risk of death while in hospital included having pre-transfusion hemoglobin done to confirm diagnosis (OR 0.5; [95% CI; 0.29-0.87]), a co-morbid diagnosis of severe malaria (OR 0.4; [95% CI;0.25-0.76]), and being reviewed after admission by a clinician (OR 0.3; [95% CI; 0.18-0.59]), while a co-morbid diagnosis of severe acute malnutrition was associated with increased risk of inpatient death (OR 4.2; [95% CI; 2.15-8.22]). Children with suspected SA who are managed according to clinical guidelines have lower in-hospital mortality than those not managed according to clinical guidelines. Efforts to reduce inpatient mortality in children with SA in resource-limited settings should focus on training, supervision, and support of health workers to adhere to clinical guidelines.

RAPID ASSESSMENT OF LYMPHEDEMA BURDEN USING MOBILE PHONE BASED TEXT MESSAGES BY COMMUNITY HEALTH VOLUNTEERS

Abdallah Ngenya[2,] Upendo Mwingira[1,2], Andrea Nshala[1,3]

[1]Tanzania Neglected Tropical Diseases Control Program, Dar es Salaam, Tanzania, [2]National Institute for Medical Research, Dar es saLaam, Tanzania, [3]IMA World Health, Dar-es-salaam, Tanzania

Lymphatic filariasis (LF) and other neglected tropical diseases (NTDs) have adopted a community-directed treatment strategy such that volunteers, referred to as community health volunteers (CHVs) are responsible for conducting mass drug administration (MDA) campaigns within their own communities. CHVs have gained valuable knowledge on the health status and conditions of their community, including LF symptoms amongst NTDs. The proposed study will be conducted in Kilwa District Lindi Region, aiming at expanding the use of CHVs to play a key role in identifying and recording of household-level information on LF morbidity cases. Knowledge of the geographical distribution of lymphedema (LE) patients is essential to ensure that morbidity management programs are targeted at the populations that need it most. Data reporters who are CHVs will be trained on how to recognize lymphedema and morbidity management. Information collected will include the case's community of residence, individual ID, age, sex, condition (lymphoedema), data is sent to a server at the National NTD office. The results of the study will be out in by June 2018 and will be reported to the in-country project team. All relevant parties within the project country will have access to the results obtained. It is anticipated that results will increase awareness of the morbidity symptoms to the local health workers and communities which will facilitate developing of a comprehensive morbidity management plan.

1231

INVESTIGATING THE CONTRIBUTION OF SEVERE MALNUTRITION TO CHILD MORTALITY AMONG CHILDREN AGED 6-59 MONTHS THROUGH THE CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS) NETWORK

Amanda L. Wilkinson[1], Jessica H. Watson[1], Rebecca P. Philipsborn[2], Quique Bassat[3], Victor Akelo[1], Shabir A. Madhi[4], Richard Chawana[4], Dianna M. Blau[1], Pratima L. Raghunathan[1], Robert F. Breiman for the CHAMPS Network[2]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Emory Global Health Institute, Atlanta, GA, United States, [3]Barcelona Institute for Global Health, Barcelona, Spain, [4]Respiratory and Meningeal Pathogens Research Unit, University of Witwatersrand, Johannesburg, South Africa

Nutritional factors are estimated to contribute to 45% of all deaths in children under five years old. However, many children die without any record of their nutritional status. Our objectives were to identify severe malnutrition (SM) among deceased children aged 6-59 months in the Child Health and Mortality Prevention Surveillance (CHAMPS) Network. Cases were classified as severely malnourished based on (a) mid-upper arm circumference <115mm, (b) WHO Child Growth Standards weight-for-length or weight-for-age z-score < -3 , (c) wasting, marasmus, or kwashiorkor noted in clinical records or listed as a cause of or contributor to death. Anthropometric measurements were collected postmortem. An expert panel systematically assigned cause of death based on laboratory, clinical, and verbal autopsy findings. In total, 101 deceased children aged 6-59 months from four countries - Mozambique, South Africa, Kenya, and Mali—were assessed after 376 cases aged <6 months of age, and 11 cases with missing data or implausible measurements were excluded. Of the included cases, 52 (52%) were severely malnourished. Clinical records were available for 85 cases; of these, four (5%) had been diagnosed with marasmic kwashiorkor, two (2%) with kwashiorkor, and 15 (18%) with wasting. Seven (8%) cases had no clinical record of malnutrition but met our anthropometric criteria for SM. The proportion of cases with SM did not differ based on age group or sex; however, all kwashiorkor cases were ≥11 months old. At the time of analysis, expert cause of death panels had reviewed and assigned cause of death in 24 cases. Of these, 10 (42%) met our definition of SM, including six cases that had malnutrition listed as a cause of or a contributor to death. SM was common among deceased CHAMPS cases aged 6-59 months with available data. As data accrue, CHAMPS will examine relationships between nutritional deficits and cause-specific mortality, improve understanding of nutrition-disease dynamics, and help identify strategies to prevent nutrition-related deaths.

1232

A STUDY OF MODIFIABLE RISK FACTORS CONTRIBUTING TO NEONATAL DEATHS (NNDS) AT BWAILA MATERNITY HOSPITAL IN LILONGWE, MALAWI

Eunice Mtingwe, Rose Mazengera, Elizabeth Chodzaza, **Elizabeth Glaser**

Kamuzu College of Nursing-University of Malawi, Blantyre, Malawi

Malawi has had success in reducing child mortality, however neonatal deaths (NNDs) remain high at 29 per 1000 live births. The objective of our study was to determine the contribution of modifiable risk factors in NNDs. We randomly sampled 110 records from a total of 375 NNDs that occurred from July 2016 to June 2017 at Bwaila maternity Hospital in Lilongwe, Malawi, a facility with 12,000 deliveries annually. We identified socio-demographic characteristics, causes of death, potentially preventable issues, and explored associations between modifiable factors and the leading cause of NND in our sample, birth asphyxia (mean 52.30%, 95% CI 42.8%-61.8%), followed by prematurity (mean 29.4%, 95% CI 20.7%-38.0%). Mothers ranged in age from 14 to 45 years old (mean 24.8, SD 6.8). Close to half had attended at least 2 antenatal visits (44.6%). Estimated gestational age of the neonates ranged from 28 to 42 weeks (mean 36.1, SD 2.9; median 37). Median weight was 2600 grams (mean 2486.9, SD 769). There was at least one of 28 modifiable factors in 92 % of the NNDs. Suboptimal intrapartum care was the most common modifiable factor. When problems were identified, interventions commenced on average 1 hour 15 minutes after detection. Labor was monitored with partograms (n 94 , 85.4%), but only 16% were completed according to standard parameters, the remaining 79 had scant documentation of Fetal Heart Rate or maternal vital signs. We found a significant inverse association between death from birth asphyxia and a complete error-free Partogram (Fisher's exact 0.010, Corr -0.2790, P>0.01); birth asphyxia was significantly and positively associated with delayed referral (Fisher's exact 0.043; Corr 0.2021, P>0.05), delayed care, (Fisher's exact 0.006; Corr 0.2786, P>0.01), and prolonged labor (Fisher's

exact 0.006; Corr 0.2760, P>0.01). Despite extensive funding and training initiatives in Malawi, neonatal deaths have not dropped. We found that the majority of neonatal losses at a large maternity centre during 2016-2017 were to infants born at a healthy weight and at term, due to largely preventable health system factors during the intrapartum period.

1233

DETERMINANTS OF MATERNAL MORTALITY IN SEVERE POSTPARTUM HEMORRHAGE IN MZIMBA DISTRICT, MALAWI

Monalisa Tembo, Alice Kadango, Abigail Kazembe, **Elizabeth Glaser**

Kamuzu College of Nursing-University of Malawi, Blantyre, Malawi

Severe Postpartum Haemorrhage is one of the main causes of maternal mortality in Malawi. This study aimed to determine the factors associated with mortality versus survival in severe PPH at both a district hospital and a tertiary care centre in Mzimba District, Northern Region, Malawi. Using a case control design we drew, via stratified random sampling, 45 cases and 45 controls of women identified as having had severe PPH (per WHO : blood loss of >1000 ml or bleeding with hypotension or blood transfusion). We used STATA 15 to calculate odds ratios (or), chisquare, and fisher's exact tests to measure the association between sociodemographic, biological, and health system factors to maternal mortality. We found very poor documentation of partograms, particularly for women transferred into the district/tertiary care facility due to complications during delivery. Our results suggests that living in a rural areas (OR 3.826, 95% CI 1.501-9.751, p=0.008), poor neonatal outcomes (OR 10.857, 95% CI 3.927-30.015, p=0.000), having to receive a c-section (OR 3.025, 95% CI 1.519-8.652, p=0.006), parity greater than 5 (OR 3.296, 95% CI 1.205-9.018, p=0.032), requiring referral prior to delivery (OR 2.985, 95% CI 1.266-7.039, p= 0.020), and pre-eclampsia (OR 6.143 , 95% CI 1.262-29.895, p=0.027) are associated with higher odds of death as compared to those that lived in urban areas, had good neonatal outcomes, parity of less than 5, not requiring referral, and those with no evidence of pre-eclampsia.Spontaneous vaginal delivery was significantly associated with survival from PPH (OR 0.297, 95% CI 0.124-0.712,p=0.011). Of note, the type of health provider in attendance was not significantly associated with either increased odds of death or survival. We found that a combination of factors were linked to increased odds of death from PPH, as such, solutions to reducing mortality due to PPH should be multimodal, among them, outreach to women with high parity to provide access to contraceptive options, access to timely transport for women with obstetric emergencies, improved provider documentation , and collaboration between the health sector and local communities.

SERIOUS SIDE EFFECTS REGISTERED POST MECTIZAN® MASS DISTRIBUTION FROM 2006 TO 2017 IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Naomi Awaca[1], Didier Muteba[1], Jean Paul Tambwe[1], Lebon Safari[1], Sylvai Mupoyi[1], Thierry L. Bobanga[2]

[1]Programme national de Lutte contre les maladies négligées, Kinshasa, Democratic Republic of the Congo, [2]Département de Médecine Tropicale, Faculté de Médecine, Université de Kinshasa, Kinshasa, Democratic Republic of the Congo

The Democratic Republic of the Congo is a country endemic to Neglected Tropical Diseases including onchocerciasis It has 23 operational coordinations, of which 15 with Onchocerciasis-Loase co-endemicity; In these areas of co-endemicity there is a high risk of serious side effects post Ivermectin (Mectizan®) mass distribution (MD). First serious side effects (SSE) cases with death were noted in 2003 in 2 co-endemic coordinations. The objective of the study is to evaluate the evolution of the occurrence of SSE after mass distribution by analyzing ivermectin distribution and SSE cases records since 2006. Results Since 2006 in the coordinations, it has been organized more than 10 cycles of annual MD concerning about 17 million in coordinations with co-endemic onchocerciasis and loasis. Between 2006 and 2010, the cases of SSE went from 289 to 33. And from 2011 to 2017 the cases went from 33 to 6. For deaths between 2006 and 2010 the number has increased from 9 to 0. And since 2010 no case of death has been recorded. The most frequent SSEs physical asthenia is found in 90% followed respectively 50%, 40%, 30%, 30% and 10% for intense pruritus, language disorders, sphincter relaxation, conjunctival hemorrhages and unconsciousness. The average time of occurrence of the SSEs is 2 days. Ringer's lactate and 10% glucose serum are administered to all patients in addition to the symptomatic treatment that is specific. Conclusion Since 2010 the number of SSE has greatly reduced and the cases of death are no longer observed. All cases observed in 2017 occurred among people who were taking Mectizan for their first time.

1235

ACCEPTANCE OF MINIMALLY INVASIVE AUTOPSIES - FROM THEORETICAL INSIGHTS TO PRACTICAL EXPERIENCE IN MOZAMBIQUE

Khatia R. Munguambe[1], Maria Maixenchs[2], Rui Anselmo[1], Jaume Ordi[2], Inacio Mandomando[1], Elizabeth O´Mara[3], Pratima Raghunathan[3], Robert Breiman[3], Quique Bassat[2], Clara Menendez[2]

[1]CISM, Maputo, Mozambique, [2]ISGlobal, Hospital Clinic - Universitat de Barcelona, Barcelona, Spain, [3]Emory Global Health Institute, Atlanta, GA, United States

The Minimally invasive Autopsy (MIA) consists of post-mortem tissue sampling for histopathological and microbiological assessments for cause of death investigation. It may potentially increase consent to post-mortem investigation compared to the full autopsy. This study aimed to predict and monitor the acceptance of MIAs among relatives of deceased individuals and factors determining it. The study was conducted in two health facilities in Southern Mozambique. Theoretical acceptance data was abstracted from 46 interviews with relatives of recently deceased individuals (17 were children) before the implementation of MIAs. Interviews generated data on whether and why respondents would agree to a MIA on the deceased relative. Actual acceptance was derived from 120 MIA eligible cases during the first year of MIA implementation. Direct observations of 47 informed consent sessions complemented the information on barriers to acceptance. Data analysis comprised calculation of proportions of theoretical and actual acceptance of MIAs and a description of acceptance determinants. Theoretically, 80% of respondents would consent to a MIA on a deceased relative of any age, and 94% would consent to MIA if the deceased was a child. Barriers to theoretical acceptance were personal principles (emotional attachment, religious convictions, confidentiality and scepticism about the value of the MIA), as well as practical aspects of family decision-making, incompatible timings, and economic constraints. Actual consent rate during the MIA implementation reached 82%. Barriers to actual acceptance were related to health facility preparedness, logistics and decision-making power. High rates of acceptance were similar between the theoretical insights and practical experience of the MIA implementation in Mozambique. It is crucial to assess acceptance and its determinants in advance of the implementation of a complex intervention. Further dimensions of acceptability besides consent must be studied and caution is needed not to overlook health-system and logistical barriers beyond personal, relational, social and cultural barriers.

1236

QUALITY OF LIFE CHANGES AND POST-OPERATIVE FOLLOW-UP OF HYDROCELE SURGERY PATIENTS

Roland Bougma[1], Issouf Bamba[2], Ines M.F. Traore[1], Jean-Paul Djiatsa[2], Fanny Yago[2], Zeina Sifri[3], Stephanie Parker[3], Stefania Slabyj[3], Emily Gower[4]

[1]Ministry of Public Health, Ouagadougou, Burkina Faso, [2]Helen Keller International, Ouagadougou, Burkina Faso, [3]Helen Keller International,

New York, NY, United States, [4]University of North Carolina, Chapel Hill, NC, United States

Over the past two years, the USAID-funded Morbidity Management and Disability Prevention (MMDP) Project supported Burkina Faso's National Lymphatic Filariasis Control Program in its efforts to provide quality surgical services to patients suffering from hydrocele. In partnership with the ministry of health, the MMDP Project provided capacity building and hydrocele surgery training activities to local surgeons in select project districts. The training was conducted using the FASTT (Filaricele Anatomical Surgical Task Trainer) training package, which consists of didactic presentations, videos on patient management emphasizing the resection technique, and supervised practice on a surgical simulator and then on patients. Trained surgeons operated on hydrocele patients during and following the training, and as a patient care and quality assurance measure, the project conducted patient follow-up in collaboration with the ministry of health. Sixty-one individuals who had hydrocele surgery as a part of the project and who were in the 6-12 month post-surgery period during the study were identified, and all were enrolled. All patients expressed that they were very satisfied and/or would recommend the surgery to others suffering from hydrocele. All patients, mostly farmers, also reported that they noticed improvements in their capacity to conduct daily tasks, and 59 of 61 (97%) patients reported improvements in their social interactions. One patient, who initially had a bilateral hydrocele, had a unilateral recurrence and was referred to the hospital for surgery. Patients were enthusiastic about their outcomes and participation in this study to be able to tell their stories. Patient outcome results reveal positive quality of life changes and successful hydrocele surgeries, which would support the training approach used and confirm the importance of patient follow-up to ensure the provision of quality surgical services.

1237

COMMUNITY-BASED APPROACH TO IDENTIFY HYDROCELE CASES: RESULTS OF A PILOT IN FIVE HEALTH DISTRICTS IN CAMEROON

Biholong Benjamin[1], Julie Akame[2], Yannick Nkoumou[2], Michel Hendji[2], Zeina Sifri[3], Stephanie Parker[3], Medesse Sonou[3], Whitney Goldman[3], Stefania Slabyj[3]

[1]Ministry of Public Health, Yaounde, Cameroon, [2]Helen Keller International, Yaounde, Cameroon, [3]Helen Keller International, New York, NY, United States

In 2017, the USAID-funded Morbidity Management and Disability Prevention (MMDP) project partnered with the national lymphatic filariasis (LF) control program in Cameroon to implement a pilot project focused on the management of LF-related morbidity in five health districts in the North and Far North regions. We selected these areas as they were believed to have the highest number of cases, estimated using data gathered through other neglected tropical disease interventions for LF. The pilot included the development and implementation of a community-based approach for the identification and referral of hydrocele cases, with the hopes of providing a more refined estimate and identification mechanism to ensure those with hydrocele could be identified in their community and referred for services. Using a community-based approach enabled potential cases to be screened closer to home, without needing to travel sometimes long distances to a health center. The project supported the development and distribution of 2,000 visual guides to assist with case identification. These were used by 1,932 community mobilizers for initial case identification. In addition, 88 health area nurses were trained in preliminary hydrocele diagnosis techniques and referral. The community mobilizers held community meetings to provide information on LF, screen and register suspected cases, and refer them to a health facility for clinical confirmation. Using this community-based approach, the community mobilizers identified 834 suspected hydrocele cases, out of which 300 (36%) were subsequently confirmed by the trained nurses at the health facilities. Of these, for logistical and planning purposes, a total of 95 cases were referred to a district hospital where surgeons trained under the MMDP Project confirmed the diagnosis in all 95 cases and operated on the patients. The remaining 205 registered cases are awaiting surgery. In view of these results, the community-based approach to identify hydrocele cases using community mobilizers and nurses appears to be feasible as a method to detect and refer hydrocele cases for management.

1238

ALTERED LEVELS OF ANGIOGENIC AND INFLAMMATORY MEDIATORS DURING PREGNANCY ARE ASSOCIATED WITH PRETERM BIRTH IN MALAWIAN WOMEN

Andrea Weckman*[1], Robyn Elphinstone*[1], Vanessa Tran[2], Andrea L. Conroy[3], Kathleen Zhong[2], Mwayiwawo Madanitsa[4], Linda Kalilani-Phiri[4], Victor Mwapasa[4], Feiko O. ter Kuile[5], Chloe McDonald[2], Kevin C. Kain[6]

[1]Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada, [2]Sandra Rotman Centre for Global Health, University Health Network, Toronto, ON, Canada, [3]Department of Pediatrics, Indiana University School of Medicine, Indianapolis, IN, United States, [4]College of Medicine, University of Malawi, Blantyre, Malawi, [5]Department of Clinical Sciences, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [6]Tropical Disease Unit, Department of Medicine, University of Toronto, Toronto, ON, Canada

Preterm birth (delivery <37 weeks gestation; PTB) is the leading global cause of death in children under five. Despite the increasing global burden of PTB, we know little about its underlying pathobiology. Tight regulation of angiogenic and inflammatory mediators are essential for healthy pregnancies. We hypothesize that disruption of pathways controlling placental vascular development and maternal inflammation precedes and contributes to PTB. Here, we validate and extend our previous findings in Tanzanian women to an external cohort of Malawian women. Samples were collected as part of a larger randomized control, multi-site trial of malaria prevention strategies in pregnancy. Longitudinal plasma samples were analyzed at three windows across gestation (16-24, 28-33, and 34-37 weeks; ultrasound dated) by multiplex luminex assays for a panel of angiogenic and inflammatory mediators previously implicated in PTB. Of the total cohort (n=1506), 304 (20.2%) delivered preterm. Multivariate log-binomial regression (adjusted for confounding factors) showed women with plasma levels of sTNFR2 ($p<0.005$), CHI3L1 ($p<0.05$), and IL18BP ($p<0.05$) in the highest quartile at enrolment (16-24 weeks) had an increased relative risk of PTB, compared to women with plasma levels in the lowest quartile. Furthermore, longitudinal analysis of biomarkers across pregnancy using linear mixed effects modeling showed that preterm pregnancies had altered kinetics over pregnancy for Ang2, sEng, sFlt1, CRP, CHI3L1 (all $p<0.05$), IL18BP ($p<0.01$), PlGF, and sTNFRII (both $p<0.001$) compared to term pregnancies. Malawi has the highest burden of PTB worldwide, with close to 1 in 5 babies born preterm each year. Understanding the pathobiology of PTB is critical to developing effective interventions. Our data indicate a role for altered longitudinal dynamics of angiogenic and inflammatory pathways in the etiology of PTB, and confirm previous findings that early biomarker profiles may identify pregnancies at risk of PTB.

1239

MASS SCREENING CAMPAIGNS TO INCREASE AWARENESS OF CERVICAL CANCER TREATMENT AND PREVENTION IN EQUATORIAL GUINEA

Olivier Tresor Donfack[1], Manuel Ondo[2], Carolina Amadu[1], Ken McGhee[3], Evelyne Chumo Mata[3], Carlos Cortes Falla[1], Guillermo Garcia[4]

[1]Medical Care Development International, Malabo, Equatorial Guinea, [2]Ministry of Health and Social Welfare, Malabo, Equatorial Guinea, [3]Noble

Energy Inc, Malabo, Equatorial Guinea, [4]Medical Care Development International, Silver Spring, MD, United States

Cervical cancer is the fourth most frequent cancer in women and represents 7.9% of all female cancers. In 2015 it was estimated that approximately 90% of all deaths due to cervical cancer occurred in low and middle-income countries. The risk of cervical cancer can be reduced with current vaccines that protect against cancer-causing types of the Human Papilloma Virus (HPV), which in conjunction with early diagnosis, effective screening, and treatment may further reduce mortality and increase prevention. Screening aims to detect and treat cancers at early stages. Cervical cancer awareness, access to screening and early diagnosis are very limited in Equatorial Guinea, therefore posing a barrier to effective prevention. In October 2016 Medical Care Development International (MCDI), funded by Noble Energy Inc, launched a Cervical Cancer Screening and Treatment (CCST) project. As part of this project Cervical Cancer Screening Corners (CCSCs) were established in two regional hospitals in the cities of Malabo and Bata as well as mass screening campaigns. The screening campaigns, which target women aged 20-26 years of age, aim to detect, treat and refer cases, as defined by lesions in the cervix, for specialized follow-up. Screening methods include visual inspection, Acetic Acid (VIA), and cold coagulation therapy. Other campaign activities include the sensitization of women to attend CCSCs, through Information, Education and Communication (IEC), and capacity development of government officials to implement prevention programs. Since the inception of the CCST project, about 2,500 women have been screened on the continental region of the country against almost 1,500 on Bioko Island. Moreover, for each campaign that is organized, community members receive training on IEC to support sensitization amongst the population of the areas they live in; and over 60 health workers across the country have attended short courses to implement screenings and cold coagulation treatments as part of their training for cervical cancer management.

1240

INCIDENCE AND RISK FACTORS FOR CERVICAL CANCER AND PRE-CANCEROUS LESIONS IN EQUATORIAL GUINEA

Megan Perry[1], Olivier Tresor Donfack[2], Manuel Ondo[3], Carolina Amadu[3], Carlos Cortes Falla[2], Luis Benavente[1], Guillermo Garcia[1]

[1]Medical Care Development International, Silver Spring, MD, United States, [2]Medical Care Development International, Malabo, Equatorial Guinea, [3]Ministry of Health and Social Welfare, Malabo, Equatorial Guinea

According to the World Health Organization, 34 out of every 100,000 women are diagnosed with cervical cancer and 23 out of 100,000 cases are fatal. Routine screen and treat programs can prevent 80% of cervical cancers as it allows for early detection of cervical cancer and pre-cancerous lesions and at earlier stages there are more effective treatment opportunities. The Human Papilloma Virus (HPV) has been associated with the risk of cervical cancer and the HPV vaccine, along with screen and treat programs, has proven to reduce incidence of cases. In Equatorial Guinea the Cervical Cancer Screen and Treat (CCST) project, funded by Nobel Energy Inc., aims to provide early routine screening, early diagnosis, and effective treatment of cervical cancer and pre-cancerous lesions to women in areas where diagnosis and treatment is limited. The project was launched in 2016 in the Regional Hospitals in Malabo (Insular Region), and Bata (Continental Region) and has screened about 4,000 women. Routine data from the project provides insight into the background and potential risk factors, as well as symptoms at the time of screening. Descriptive data analysis and linear regression models will provide an overview of the associations between potential risk factors and symptoms and the outcome of the screening test. The data analysis will also allow for insight into the profile of women who participate in the cervical screening program. This study will be valuable to support future Information, Education and Communication (IEC) campaigns, targeted mass screening campaigns and treatment programs which include training of health care workers.

ENVIRONMENTAL SUITABILITY FOR LYMPHATIC FILARIASIS IN NIGERIA

Obiora A. Eneanya[1], Jorge Cano[2], Tini Garske[1], Ilaria Dorigatti[1], Christl A. Donnelly[1]

[1]Imperial College London, London, United Kingdom, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom

Lymphatic filariasis (LF) is a mosquito-borne parasitic disease and a major cause of disability worldwide. It is one of the neglected tropical diseases identified by the World Health Organization for elimination as a public health problem by 2020. Maps displaying disease distribution are helpful tools to identify high risk areas and target scarce control resources. Using site level occurrence data consisting of 1378 data points collected during extensive mapping surveys by the Federal Ministry of Health, Nigeria, we implemented an ensemble of machine learning modelling algorithms (generalised boosted models and random forest). We mapped the ecological niche of LF at a spatial resolution of 1km^2. And by overlaying gridded estimates of population density, we estimated the human population living in LF risk areas on a 100m x 100m scale. Our maps demonstrate that there is a heterogeneous distribution of LF risk areas across Nigeria, with large portions of northern Nigeria having more environmentally suitable conditions for the occurrence of LF. Here we estimated that approximately 103 million individuals live in areas at risk of LF transmission. Machine learning and ensemble modelling are powerful tools to map disease risk, and are known to yield more accurate predictive models while decreasing the uncertainty of single models. The resulting map provides a geographical framework to target control efforts and assess its potential impacts.

MODELLING LYMPHATIC FILARIASIS TRANSMISSION IN AMERICAN SAMOA LONG-TERM POPULATION DYNAMICS AND SPATIALLY HETEROGENEOUS RISKS

Zhijing Xu[1], Kathryn Glass[1], Colleen Lau[1], Nicholas Geard[2], Patricia Graves[3], Archie Clements[1]

[1]The Australian National University, Acton, Australia, [2]University of Melbourne, Melbourne, Australia, [3]James Cook University, Carins, Australia

Although considerable success has been achieved to eliminate lymphatic filariasis since 1999, there are significant knowledge gaps about LF transmission dynamics, particularly at the end stages of elimination programs when prevalence has reached very low levels. Current mathematical and computational models of lymphatic filariasis do not capture small-scale spatial heterogeneity of risk factors, restricting our understanding of LF dynamics at low prevalence. A new agent-based model was developed to fill the knowledge gaps about lymphatic filariasis transmission and elimination in American Samoa, but also to be readily adaptable to model other infectious diseases. The modelling framework was characterized by statistically realistic population, high-resolution geographic locations and long-term projections of the population dynamics. The population in the model is characterized by major dynamic processes including population renewal (birth/death), couple formation and separation, and migration, with daily commuting patterns predicted with the radiation model. The risk of infection was estimated based on the mosquito abundance (mosquito bites) and the prevalence of infectious individuals in the neighbourhood areas. The agent-based model in the study provides not only valuable insights into further LF dynamics based on the transmission assessment survey, but also a highly flexible modelling framework for a variety of infectious diseases, especially for diseases with long incubation and long infectious periods, or diseases with highly focal transmission hotspots.

1243

EVALUATING THE TRANSMISSION ASSESSMENT SURVEY CRITERIA FOR ELIMINATING LYMPHATIC FILARIASIS USING MATHEMATICAL MODELLING

Morgan Smith, Swarnali Sharma, Edwin Michael

University of Notre Dame, Notre Dame, IN, United States

Regions endemic for lymphatic filariasis (LF), a debilitating vector borne parasitic disease, have made substantial progress toward the global goal of interrupting transmission by 2020. Despite this achievement, there remains significant uncertainty surrounding the transmission thresholds which serve as program targets for stopping mass drug administration (MDA). The proposed target to be eligible for implementing Transmission Assessment Surveys (TAS) and potentially stopping MDA is 1% microfilariae (mf) or 2% antigenaemia prevalence in a population. Here, we employ mathematical modelling to assess whether meeting the TAS criteria implies that transmission has been interrupted, and, if not, what the risk of recrudescence after stopping MDA might be. Surveillance data from six LF endemic sites chosen for their geographic distribution and range of endemic prevalences were included in this study. Using a Bayesian Melding data assimilation framework, the models were fitted to site-specific baseline mf data in order to capture local transmission dynamics, and the calibrated models were used to simulate the impact of observed MDA on mf prevalence. The estimated timelines to achieve 1% mf prevalence in the sites ranged from 5-13 years, and the probability of interrupting transmission after stopping MDA (i.e. the probability of sustaining mf prevalence < 1%) ranged from 30-84%. Sites with lower baseline prevalence exhibited more favorable elimination outcomes compared to sites with higher endemicity. We also modeled the effect that different intervention strategies have on recrudescence risk after meeting the 1% mf threshold and found that the lowest probabilities of recrudescence were achieved when MDA was supplemented with vector control (VC). The optimal scenario was to include VC both during and after stopping MDA (1-35% probability of recrudescence) compared to MDA alone (16-61% probability of recrudescence). These results question the current criteria used for making stopping decisions and highlight the need to validate transmission thresholds with field studies to avoid the consequences of prematurely stopping MDA.

1244

SOIL-TRANSMITTED HELMINTH AND *SCHISTOSOMA MANSONI* INFECTIONS DO NOT EVOKE CROSS-REACTIVE ANTIBODIES TO THE *ONCHOCERCA VOLVULUS* PEPTIDE EPITOPES OVMP-1 AND OVMP-23

Johnny Vlaminck[1], Ole Lagatie[2], Ann Verheyen[2], Daniel Dana[3], Bieke Van Dorst[2], Zeleke Mekonnen[3], Bruno Levecke[1], Lieven Stuyver[2]

[1]Ghent University, Merelbeke, Belgium, [2]Janssen Diagnostics, Beerse, Belgium, [3]Jimma University, Jimma, Ethiopia

The Ov16 IgG4 ELISA or lateral flow test is considered the reference method for *Onchocerca volvulus* epidemiological mapping. Recently, two linear epitopes encoded in OvMP-1 and OvMP23 peptides were introduced as serological markers, but the observed antibody cross-reactivity in samples originating from *O. volvulus* non-endemic areas required further investigation. In this study, we evaluated these markers in an *Onchocerca* meso-endemic setting in Jimma, Ethiopia. For all individuals (n = 303), the infection status with soil-transmitted helminths and *Schistosoma mansoni* was known. In total, 11 (3.6%) individuals were positive for anti-Ov16 IgG4 antibodies, while 34 (11.2%) and 15 (5.0%) individuals had antibody responses to OvMP-1 and OvMP-23, respectively. Out of the 34 OvMP-1 positive samples, 33 were negative on the Ov16 IgG4 ELISA. Similarly, out of the 15 OvMP-23 positive samples, 14 scored negative on this reference method. Upon further analysis of the "false positive samples" for infection with non-*Onchocerca* helminth infections, they were not significantly correlated to soil-transmitted helminth ($p > 0.05$) or *S. mansoni* infections ($p > 0.05$). This suggests that these individuals are either infected with *O. volvulus* and were not picked up by the Ov16 IgG4 ELISA, or that they have an immune response against other agents that cause cross-reactivity. For OvMP-1, there appeared to be a significant trend towards increased seroprevalence in older individuals. The results of this work demonstrate that both OvMP-1 and OvMP23 do not cross-react with soil-transmitted helminth or *S. mansoni* infections. The discordancy with the Ov16 test requires further investigation in *Onchocerca* endemic populations.

1245

ONCHOCERCA VOLVULUS TRANSMISSION IN THE MBAM VALLEY (CENTRE REGION, CAMEROON) FOLLOWING 18 YEARS OF ANNUAL CDTI

Adam Hendy[1], Meryam Krit[1], Kenneth Pfarr[2], Hugues Nana-Djeunga[3], Jacobus De Witte[1], Philippe Nwane[3], Joseph Kamgno[3], Michel Boussinesq[4], Rory Post[5], Robert Colebunders[6], Sarah O'Neill[7], Peter Enyong[8], Alfred K. Njamnshi[9]

[1]Department of Biomedical Sciences, Institute of Tropical Medicine, Antwerp, Belgium, [2]Institute for Medical Microbiology, Immunology and Parasitology, University Hospital Bonn, Bonn, Germany, [3]Centre for Research on Filariasis and other Tropical Diseases (CRFilMT), Yaoundé, Cameroon, [4]Institut de Recherche pour le Développement (IRD), Montpellier, France, [5]School of Natural Sciences and Psychology, Liverpool John Moores University, Liverpool, United Kingdom, [6]Global Health Institute, University of Antwerp, Antwerp, Belgium, [7]Department of Public Health, Institute of Tropical Medicine, Antwerp, Belgium, [8]Research Foundation for Tropical Diseases and Environment, Buea, Cameroon, [9]Neurology Department, Central Hospital Yaoundé, Yaoundé, Cameroon

The onchocerciasis focus surrounding the lower Mbam and Sanaga rivers was historically the largest in southern Cameroon. Control through annual community directed treatment with ivermectin (CDTI) commenced in 1998 and takes place around July each year. However, recent surveys indicate that *Onchocerca volvulus* transmission is ongoing and the disease remains endemic. This study aimed to evaluate blackfly biting and parasite transmission rates after 18 years of annual CDTI. Anthropophilic blackflies were collected using human bait along the lower Mbam River near Bafia between July 2016 and June 2017. Collections were made for three consecutive days each month at four sites (two riverside; two ≥8km from the riverside). Specimens were either dissected to determine parity rates and intensity of *O. volvulus* infection or were preserved for pool screening. In total, 93,563 adult female *Simulium damnosum* s.l. were collected. Biting peaked between September and March and annual biting rates of ≥606,370 bites/person/year were recorded at riverside sites. Provisional results show that parasite transmission peaked between January and May and coincided with high blackfly parity rates. Transmission occurred almost exclusively at riverside sites, where annual transmission potentials of ≥4,488 were recorded. Cytotaxonomy of *S. damnosum* complex larvae indicated that a new variant of *Simulium squamosum* E was the predominant cytoform breeding in the area, making this the first time *S. squamosum* E has been found east of Lake Volta in Ghana. Current and pre-CDTI data suggest that *O. volvulus* transmission is sustained by high blackfly biting rates along the lower Mbam River, where it occurs mainly during the late dry and early rainy seasons. Similar seasonal patterns of transmission have been reported elsewhere in Africa where *S. squamosum* is the vector. The current timing of CDTI which takes place around July each year may not be ideal, and communities could benefit from earlier treatment, before blackfly parity rates and *O. volvulus* transmission increase.

1246

PREDICTED DISTRIBUTION AND BURDEN OF PODOCONIOSIS IN CAMEROON

Kebede Deribe[1], Jorge Cano[2], Abdel Jelil Njouendou[3], Mathias Esum Eyong[3], Amuam Andrew Beng[3], Emanuele Giorgi[4], David M. Pigott[5], Rachel L. Pullan[2], Abdisalan M. Noor[6], Fikre Enquselassie[7], Melanie J. Newport[1], Gail Davey[1], Samuel Wanji[3]

[1]Wellcome Trust Brighton and Sussex Centre for Global Health Research, Brighton and Sussex Medical School, Brighton, United Kingdom, [2]Department of Disease Control, London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Parasites and Vector Biology research unit (PAVBRU), Department of Microbiology and Parasitology, University of Buea, Buea, Cameroon, [4]Lancaster Medical School, Faculty of Health and Medicine Lancaster University, Lancaster, United Kingdom, [5]Institute for Health Metrics and Evaluation, University of Washington, Seattle, WA, United States, [6]Kenya Medical Research Institute-Wellcome Trust Collaborative Programme, Nairobi, Kenya, [7]School of Public Health, Addis Ababa University, Addis Ababa, Ethiopia

Understanding the number of cases of podoconiosis, its geographical distribution and the population at risk are crucial to estimating the burden of this disease in endemic countries. We assessed each of these using nationwide data on podoconiosis prevalence in Cameroon. We analysed data arising from two cross-sectional surveys in Cameroon. The dataset was combined with a suite of environmental and climate data and analysed within a robust statistical framework, which included machine learning-based approaches and geostatistical modelling. The environmental limits, spatial variation of predicted prevalence, population at risk and number of cases of podoconiosis were each estimated. A total of 214,729 records of individuals screened for podoconiosis were gathered from 748 communities in all 10 regions of Cameroon. Of these screened individuals, 882 (0.41%; 95%CI 0.38-0.44) were living with podoconiosis. High environmental suitability for podoconiosis was predicted in three regions of Cameroon (Adamawa, North West and North). The national population living in areas environmentally suitable for podoconiosis was estimated at 5.2 (95% Confidence Interval [CI]: 4.7-5.8) million, which corresponds to 22.3% of Cameroon's population in 2015. Countrywide, in 2015, the number of adults estimated to be suffering from podoconiosis was 41,556 (95% CI, 1,170- 240,993). Four regions (Central, Littoral, North and North West) contributed 61.2% of the cases. In Cameroon, podoconiosis is more widely distributed than was initially expected. The number of cases and the population at risk may pose a challenge to the national health system. Strengthening of the health system for early diagnosis of podoconiosis, morbidity management and follow up of cases is of utmost necessity. Promotion of footwear use and regular foot hygiene should be at the forefront of any intervention plan. Elimination of podoconiosis requires firm political will, policy formulation, operational and financial commitment by the Cameroon Ministry of Health and donors.

1247

DELINEATION OF ONCHOCERCIASIS TRANSMISSION ZONES IN ETHIOPIA; A CRITICAL ELEMENT FOR THE ELIMINATION OF ONCHOCERCIASIS

Moses Katabarwa[1], Aderajew Mohammed[2], Tewodros Seid[2], Tekola Endeshaw[2], Abebual Yilak[2], Firdaweke Bekele[2], Nebiyu Negessu[3], Kadu Meribo[4], Zerihun Tadesse[2], Emily Griswold[1], Frank Richards[1]

[1]The Carter Center, Atlanta, GA, United States, [2]The Carter Center, Addis Ababa, Ethiopia, [3]Federal Minsitry of Health, Addis Ababa, Ethiopia, [4]Federal Ministry of Health, Addis Ababa, Ethiopia

Onchocerciasis, a parasitic disease caused by a nematode worm *Onchocerca volvulus,* is transmitted through the bites of *Simulium* vector flies that breed in fast flowing rivers and streams. In its advanced form, onchocerciasis can cause visual impairment, blindness and severe skin diseases. Recently onchocerciasis intervention efforts have reoriented from control to transmission elimination. With this new goal in mind, new mapping approaches are needed to delineate transmission zones. These transmission zones are targeted for mass drug administration (MDA) with ivermectin and/or vector control programs. A transmission zone (or 'focus') is defined as an ecological or geographical area where *Onchocerca volvulus* transmission occurs by locally breeding *Simulium* vectors. Under the control paradigm of the African Onchocerciasis Control Program endemic countries were not required to delineate transmission zones. Instead Rapid Epidemiological Mapping of Onchocerciasis (REMO) used palpation examinations to determine subdermal onchocercomata (nodule) rates to define intervention areas. In the elimination era, more sensitive serological tools (Ov-16 ELISA or RDT) are being applied to define transmission zones. We describe our experience in Ethiopia using OV-16 ELISA to delineate the borders of two transmission zones (Metema and Metekel) separated by a "buffer" zone of sufficient size to allow halting of MDA in Metema. The threshold for delineating this buffer zone was the finding of <2% Ov-16 in the adult (>20 years of age) residents of buffer area of >20km separating Metema and Metekel transmission zones. It is sufficient to prevent infected *Simulium* vectors from crossing one transmission zone (Metekel) to the another (Metema). In 2017 the Metema transmission zone met the WHO criteria for stopping MDA based on OV16 ELISA rates in 7,572 young children of <0.01% and PCR results from 28,465 *Simulium* flies of 0.14 flies with L3 per 2000 (95% CI, 0.01-0.39). MDA continued in Metekel due to ongoing transmission and very high OV16 rates (25.6%) in adults.

1248

DRAMATIC AGE DISTRIBUTION SHIFT OF PEOPLE WITH EPILEPSY IN A HIGHLY ENDEMIC ONCHOCERCIASIS FOCUS OF CAMEROON WHICH HAD BENEFITED FROM MASS IVERMECTIN TREATMENT OVER 19 YEARS

Surveys conducted in 1991-93 in the Mbam valley (Cameroon) showed that onchocerciasis was highly endemic, with community microfilarial loads (CMFL) >100 microfilariae/snip in some villages. In 1991, a census of suspected cases of epilepsy (SCE) using a questionnaire applied to individuals identified by key informants identified 746 SCE revealing prevalences up to 13.6%. From 1998, annual mass ivermectin treatment (MIT) was implemented to control onchocerciasis. In 2017, a door-to-door household survey was conducted in 3 villages visited in 1991, using a 5-item epilepsy screening questionnaire. A total of 2286 individuals living in 324 households were screened (582 in Bayomen, 553 in Ngongol and 1151 in Nyamongo) and 112 SCE were identified (4.9%). Neurologists

confirmed the diagnosis of epilepsy in 81 (3.5%), rejected the diagnosis in 11; 20 SCE could not be examined. Between 1991 and 2017, the prevalence of SCE decreased from 13.6% to 2.5% in Bayomen (p=0.001), from 8.7% to 6.6% in Ngongol (p=0.2), and from 6.4% to 5.4% in Nyamongo (p=0.28). The median age of SCE shifted from 20 (IQR 12-23) to 29 years (IQR 18-33; p=0.018) in Bayomen, from 16 (IQR 12-21) to 26 years (IQR 21-39; p<0.001) in Ngongol and from 16 (IQR 13-19) to 24 years (IQR 19-32; p<0.001) in Nyamongo. The proportions of SCE aged ≤15, 15-30 and >30 years were 41.7, 51.2 and 7.1% in 1991 and 11.6, 58.9, and 29.5% in 2017, respectively. This age shift is probably due to decrease in the incidence of onchocerciasis associated epilepsy resulting from the dramatic reduction in the CMFL following 19 years of MIT. The fact that the prevalences recorded in 1991 and 2017 did not differ significantly in Ngongol and Nyamongo might be due (i) to a lower MIT coverage (the coverage was probably higher in Bayomen, where the village chief was also the drug distributor), (ii) to a better access to anti-epileptic drugs and thus a longer lifespan of SCE cases after 1991, or (iii) to an under-estimation of the SCE prevalences in 1991.

1249

IMPACT OF FORTY YEARS INTERVENTION TO CONTROL ONCHOCERCIASIS IN COTE D'IVOIRE

Benjamin G. Koudou[1], Marie-Madeleine Kouakou[2], Yeo Soudeymane[3], Aboulaye Meite[2], Roger Kouakou[3], Gary J. Weil[4], Peter U. Fischer[4]

[1]University of Nangui Abrogoua, Abidjan, Côte D'Ivoire, [2]National Onchocerciasis Control Programme, Ministry of Public Health and HIV Control, Cote d'Ivoire, Abidjan, Côte D'Ivoire, [3]Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Abidjan, Abidjan, Côte D'Ivoire, [4]Washington University School of Medicine, St. Louis, MO, United States

To better coordinate and plan the elimination of onchocerciasis in Cote d'Ivoire we reviewed the impact of past interventions performed between 1974 and 2013. Onchocerciasis control started with aerial insecticide spraying and continued with community directed treatment with ivermectin (CDTi) from 1992 to present. We analysed microfilaria (MF, skin snip) prevalence and community MF load (CMFL) data reported from 39 health districts during two major epidemiological assessment periods. Data from 1975 through 1991 provided information on vector control impact, and data from 1992 through 2013 provided information on CDTi impact. Weekly aerial insecticide spraying in 8 endemic districts between 1974 and 1991 reduced the overall MF prevalence by 54% from 43.1% to 17.2%. The CMFL also decreased in 7 out of 8 surveyed communities by 69% from 9.85 MF/snip to 1.1 MF/snip. The CDTi coverage target for control was reached in most endemic districts, and some areas achieved 80% coverage. Two sets of surveys were conducted to assess the impact of CDTi. The first set of repeat surveys (1992-2002) showed a significant drop in overall MF prevalence by 73.9% (from 29.8% to 7.78 %). The second follow up evaluation (2007-2013) showed a significant reduction in overall MF rates by 71.0% from baseline (from 29.8% to 8.65%). The first and second follow up surveys also documented strong reductions in CMFL compared to baseline (from 7.67 MF/ snip to 0.61 MF/ snip and from 7.67 MF/snip to 0.70 MF/ snip, respectively). Between the first and the second set of follow up surveys the MF rates and CMFL were fairly stable at low levels without much further reduction. Currently, onchocerciasis and lymphatic filariasis (LF) are co-endemic in 46 of the 81 health districts, and 12 districts are endemic for onchocerciasis only. In conclusion, data collected over 40 years showed significant success of interventions conducted by the national onchocerciasis control programme during challenging times. The Health Ministry has now integrated efforts to control and eliminate neglected tropical diseases, and based on the most recent data it is working hard toward onchocerciasis elimination.

1250

LINEAR EPITOPES IN *ONCHOCERCA VOLVULUS* VACCINE CANDIDATE PROTEINS, EXCRETORY-SECRETORY PROTEINS, AND SERODIAGNOSTIC CANDIDATES

Ole Lagatie[1], Ann Verheyen[1], Erik Nijs[1], Linda Batsa Debrah[2], Alex Debrah[3], Tania Supali[4], Erliyani Sartono[5], Lieven J. Stuyver[1]

[1]Janssen Diagnostics, Janssen R&D, Beerse, Belgium, [2]Kumasi Centre for Collaborative Research into Tropical Medicine, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [3]Faculty of Allied Health Sciences, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [4]Department of Parasitology, Faculty of Medicine, Universitas Indonesia, Jakarta, Indonesia, [5]Department of Parasitology, Leiden University Medical Center, Leiden, Netherlands

There is a growing need for diagnostic tools to monitor infection with the helminth parasite *Onchocerca volvulus*. In previous studies, a proteome-wide screen was conducted to identify linear epitopes in this parasite's proteome, resulting in the discovery of 1110 antigenic peptide fragments. Here we investigated whether such peptides were found in proteins that were already known as vaccine candidates, excretome/secretome proteins, and/or serodiagnostic protein candidates for *O. volvulus*. This approach led to the identification of 35 immunoreactive peptides in 23 proteins. We developed peptide ELISA's and evaluated their diagnostic sensitivity and specificity. For 8 of those peptides, epitope mapping was performed and peptides were constructed that contained only the minimal epitope, flanked by a linker. The following plasma samples were available for ELISA peptide testing: 101 samples from onchocerciasis patients, 159 from non-helminth infected individuals, and 50 from individuals infected with other helminths (10 with *Wuchereria bancrofti*, 20 with *Brugia malayi* and 20 with soil-transmitted helminths). Investigation of the performance of these minimal epitope peptides demonstrated that three of them (OvNMP-14, OvNMP-16 and OvNMP-18) have a specificity of 100%, low cross-reactivity (8.0%, 6.0%, and 4%, respectively), but intermediate sensitivity (36.9%, 46.5%, and 41.2%, respectively). A theoretical assessment of the performance of a combination of these three peptides showed that sensitivity could be further increased to 77.2% without compromising specificity. In this work, the linear epitopes discovered were found in secretory/excretory proteins or serodiagnostic candidates, but none of them was found in vaccine candidate proteins. This would indicate that of all the vaccine candidate proteins that were included in this analysis, none would bear immunodominant linear epitopes that are recognized by infected non-vaccinated individuals.

1251

IMPLEMENTING THE SUPERVISOR'S COVERAGE TOOL IN AN URBAN SETTING: A CASE STUDY IN PORT-AU-PRINCE, HAITI

Tara A. Brant[1], Alain Javel[2], Anita Sircar[1], Carl Fayette[2], Amber M. Dismer[1], Franck Monestime[2], Ellen Knowles[3], Sarah Craciunoiu[3], LeAnne M. Fox[1], Jean-Frantz Lemoine[4], Caitlin M. Worrell[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]IMA World Health, Port-au-Prince, Haiti, [3]IMA World Health, Washington, DC, United States, [4]National Program to Eliminate Lymphatic Filariasis, Ministry of Public Health and Population, Port-au-Prince, Haiti

The ability to achieve and maintain high drug coverage during mass drug administration (MDA) for lymphatic filariasis (LF) is critical for achieving the Global Programme to Eliminate Lymphatic Filaraisis goal of interrupting transmission by 2020. In Haiti, the urban communes of metropolitan Port-au-Prince (PaP) have struggled to achieve adequate drug coverage (≥ 65%) during each round of MDA for LF. In order to rapidly assess drug coverage during the 2017 MDA, the Ministry of Public Health and Population (MSPP) and partners implemented the World Health Organization (WHO) recommended Supervisor's Coverage Tool (SCT) in Butte Boyer, a sub-section of Tabarre commune, in PaP one week following the MDA. The community leader and 12 promoters (first-line supervisors) used purposive and random sampling to select six supervision areas (SA) in which to

conduct SCT. Twenty households were randomly selected from each of the SAs; one respondent per household was asked to report if they were offered and consumed the drugs during MDA, as well as reasons for non-participation. Among 120 respondents, mean age was 31 years, 45 (38%) were male. The SCT results indicated inadequate coverage in all six SAs, defined as 10 or fewer respondents consuming the medication. The primary reasons given by respondents for not being offered or not consuming the drugs were absence during MDA and fear of side effects, respectively. Results were consistent with the low reported administrative coverage for Tabarre commune (56%). Following the SCT implementation, promoters and leaders discussed reasons for low coverage and proposed new strategies to address low coverage in their SAs. These strategies were the basis for a new urban MDA protocol aiming to improve coverage in this complex setting. Further, the SCT should be considered as a tool to rapidly assess drug coverage if MSPP adapts the new triple drug therapy in Haiti.

1252

THE RELATIVE IMPACT OF ANNUAL AND SEMIANNUAL MASS DRUG ADMINISTRATION (MDA) ON LYMPHATIC FILARIASIS AND ONCHOCERCIASIS IN COTE D'IVOIRE

Aboulaye Meite[1], Olivier Kouadio[2], Benjamin G. Koudou[3], Gary J. Weil[4], Peter U. Fischer[4]

[1]National Onchocerciasis Control Programme, Ministry of Public Health and HIV Control, Cote d'Ivoire, Abidjan, Côte D'Ivoire, [2]Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Abidjan, Côte D'Ivoire, [3]Laboratory of Biology and Animal Cytology, Training and Research Unit in Sciences of Nature, University of Nangui Abrogoua, Abidjan, Côte D'Ivoire, [4]Washington University School of Medicine, St. Louis, MO, United States

Lymphatic filariasis (LF) and onchocerciasis are co-endemic in 64 of 82 health districts in Côte d'Ivoire. Both filarial infections are targeted for elimination and mass drug administration (MDA) using ivermectin alone (onchocerciasis) or in combination with albendazole (LF) is the main intervention strategy. We compared the impact of annual and semi-annual MDA with ivermectin and albendazole in Abengourou and Akoupé districts in eastern Côte d'Ivoire. Baseline surveys were performed in 4 sentinel villages per district in 2014, and follow-up surveys were carried out in 2015, 2016 and 2017. We assessed microfilaria (Mf) prevalence for both infections and circulating filarial antigen rates by FTS for LF. Three annual rounds of MDA in Abengourou district decreased the LF Mf prevalence from 9.5% to 3.5% (63% reduction) and the onchocerciasis Mf prevalence from 23% to 9.6% (59% reduction). Five semiannual rounds of MDA in Akoupe decreased the LF Mf prevalence 7.6% to 2.8% (63% reduction), but the prevalence was less than 1% in 2 of the 4 sentinel villages. FTS prevalence decreased from 24.2% to 12.6% (48% reduction) in the annual MDA area and from 25.6% to 11.6% (55% reduction) in the semiannual MDA area. Thus, 5 rounds of MDA was slightly more effective than 3 rounds for reducing LF and onchocerciasis prevalence over a 3 year period. However, the differences observed were less impressive than those predicted by modeling studies, and they may not justify the increased cost and effort required for providing semiannual MDA. Given resource restraints, we believe that disease elimination programs should focus on achieving high rates of therapeutic coverage and not struggle to increase the frequency of MDA.

1253

SOIL TRANSMITTED HELMINTHS INFECTION AND ASSOCIATED RISKS STILL A PREVALENT ISSUE IN NIGERIA; PRIMARY SCHOOL CHILDREN ASSESSMENT IN OWO LOCAL GOVERNMENT AREA OF ONDO STATE, NIGERIA

Funmilayo S. Oluwafemi, Babatope E. Alo, Fred C. Akharaiyi, Toluwani B. Agunbiade

Afe Babalola Universty, Ado-Ekiti, Ado-ekiti, Nigeria

Soil transmitted helminths' infections are one of the major public health problems in many tropical countries including Nigeria. The objective of the present study was to assess the prevalence of soil transmitted helminths' infections and associated risk factors among primary school children of Owo LGA in Ondo State. The design of the study was a cross-sectional survey involving 224 children aged 5-15 years old who were chosen using random sampling technique from four primary schools. Data were gathered by means of questionnaire survey and laboratory parasitological examination procedures. .A structured and pre tested questionnaires were administered to study participant to collect information on socio-demographic characteristics and risk factor. The pupil BMI was measured, blood samples was assessed for hemoglobin (Hb) and PCV level while stool samples were examined for STH infection using direct wet-mount and Formol-Ether concentration methods. Data were analyzed using SPSS version 20.0. Of the total 224 study participants examined, 50.4% were males and 49.6% female children. It was found that 54 (47.8%) male and 59 (52.2%) female children were infected with STH parasites. Thus, the overall prevalence of infections of STH parasites was 50.4%. The STH parasites species identified in school children were *Ascaris lumbricoides*, hookworm and *Trichuris trichuira* with prevalence of 25.9%, 16.1% and 2.2% respectively. The prevalence of STH parasite infections among school children in age group 6-10 and 11-15 were 59.3% and 40.7%, respectively. There was no significant association between STH parasite infections and parent occupation, knowledge of hygiene/sanitation ($p>0.05$). Factors like source of attitude/practice of hygiene, drinking water source, type of toilet facility, hand washing habit before meal and after toilet were significantly associated with STH parasites infection ($P<0.05$). Local health sector should collaborate with school health program for delivering health education to increase the knowledge, attitude and practice of school children.

1254

INVESTIGATING THE IMPACT OF REPEATED, COMMUNITY-WIDE, MASS DRUG ADMINISTRATION ON THE AGGREGATION OF SOIL-TRANSMITTED HELMINTH INFECTION

James E. Wright, James E. Truscott, Sam H. Farrell, Roy M. Anderson

Imperial College London, London, United Kingdom

It has been widely shown that human helminth infections are highly aggregated, with a minority of individuals harbouring most worms. At equilibrium, the negative binomial distribution is used to describe this overdispersion, with aggregation denoted by the clustering parameter, *k*. Recent observations have suggested that repeated rounds of mass drug administration cause aggregation to increase. However, the causative mechanism by which this may occur has not yet been researched. An individual-based stochastic model was used to simulate the effect of annual mass drug administration on hosts' worm burdens. The Bliss & Fisher method was used to estimate the change in effective aggregation of worms in the host population under the effect of treatment and across a range of ages. We also analysed the contribution of age-intensity infection profiles and treatment events to the variance of worm burden in a sampled population. From this overall variance, the effective aggregation can be estimated. Further, by analysing the contribution of various sources of variance we can identify which factors are driving changes in variance

and hence aggregation. Immediately after each round of treatment, mean worm burden drops and worm aggregation spikes. In both cases, equilibrium is rapidly restored. Upon cessation of treatment, aggregation remains at equilibrium levels in villages which do not reach elimination whereas it increases drastically in those which successfully eliminate. Analysis of the variance in worm population pre- and post-treatment produces *k* estimates closely matching those observed from the simulation. Estimates for the change in *k* incorporating age-structure also showed high levels of accuracy. A relationship was identified between the change in aggregation, the efficacy and coverage of treatment, and the initial aggregation value. We have shown that repeated, community-wide mass drug administration causes worm aggregation to spike in the short-term, and either maintain equilibrium or drastically increase in the longer-term, depending on a village's elimination success.

1256

VERMOX® (MEBENDAZOLE) CHEWABLE TABLET - DEVELOPING A CHILD-FRIENDLY SOLUTION TO ELIMINATE SOIL-TRANSMITTED HELMINTHS THROUGH PREVENTIVE CHEMOTHERAPY

Benny Baeten[1], Viviam Cañon[1], Marc Engelen[1], Ernesto Fernandez[2], Mark Kao[3], Joe Massarella[3], Daniel Schaufelberger[3], Lieven Stuyver[1], Melissa Tokosh[3], Cori Vail[3]

[1]Janssen R&D & Global Public Health, Beerse, Belgium, [2]Janssen R&D & Global Public Health, Zug, Switzerland, [3]Janssen R&D & Global Public Health, Raritan, NJ, United States

An estimated 1.5-2 billion people are infected with Soil-Transmitted Helminths (STH), with the highest prevalence in children living in communities without adequate sanitary facilities, safe potable water and/or basic hygiene practices. The World Health Organization (WHO) recommends regular deworming of target populations through preventive chemotherapy (PC), to reduce the negative impact of STH on nutritional status, and cognitive and physical development. PC consists mainly of the annual or bi-annual administration of the benzimidazole anthelmintics albendazole and mebendazole (MBZ). Johnson & Johnson annually donates 200 million MBZ tablets to the WHO for distribution to endemic countries. In line with WHO recommendations on deworming young children, J&J recently developed a new chewable 500-mg MBZ tablet, which rapidly disintegrates after addition of a small amount of water. This makes the tablet much more suitable for young children and will likely reduce the risk of choking. Readily available, non-proprietary technology was used to develop the chewable tablet. Non-clinical studies were limited to two dog PK studies, as the preclinical characterization with previous MBZ formulations was considered to remain valid. Four clinical trials were performed: two Phase 1 trials (one relative bioavailability and one food effect study), one Phase 3 safety trial in children, and one Phase 3 efficacy and safety trial in children with analysis of PK parameters in a subset of subjects. The MBZ 500-mg chewable tablet was approved by the FDA in October 2016 for the treatment of STH infections by *Ascaris* and *Trichuris* in patients as of 1 year of age. A dossier to seek Prequalification for the treatment of infections by *Ascaris*, *Trichuris* and hookworm species is currently under review by WHO. The authors will describe the development path followed for this new chewable tablet, as well as the plans to include it in J&J donation programs, once WHO prequalified. Its physicochemical properties will make the tablet easier and safer to administer, esp. in young (12-23 months) and preschool children (24-59 months).

1257

COMPARISON OF PCR DIAGNOSTIC WITH KATO KATZ TECHNIQUE FOR DIAGNOSIS OF SOIL TRANSMITTED HELMINTHS AND SCHISTOSOMIASIS INFECTIONS IN THE AYALOLOO CLUSTER OF SCHOOLS IN THE ACCRA METROPOLIS OF GHANA

Buhari Adamu B. Hamidu[1], Elias E. Asuming-Brempong[2], Bright B. Idun[1], Mike M. Osei-Atweneboana[1]

[1]Council for Scientific and Industrial Research - Water Research Institute, Accra, Ghana, [2]Noguchi Memorial Insitute for Medical Research - University of Ghana, Accra, Ghana

The greatest impact of Soil Transmitted Helminth (STH) infections andschistosomiasis (SCH) is on the impairment of physical and intellectual development in children.According to WHO, 2012, In Ghana, STH infections are reported to be more prevalent amongchildren of school – going age, hence the renewed commitment by major stakeholders toincrease current school-based MDA coverage in the country to 75% by 2020. However, underprevalence report is a major setback to this control targets. Accra Metropolis is listed as one of the low prevalence region in Ghana. A total of 120school children between the ages of 5-17 years were recruited from two schools within theAyalolo cluster of schools in the Accra Metropolis. Stool samples collected and processed at theparasitological and molecular biology laboratories of the Biomedical and Public Health ResearchUnit (BPHRU), CSIR-Water Research Institute respectively. All helminth infections recorded in this exercise were from the Central Mosque Primaryschool. The most prevalent infection for STH was *Ascaris lumbricides* at a prevalence of 9.62%,however, *Ancylostoma doudenale* (hookworm) was observed at a prevalence of 3.3%. There wasno infection recorded at the Ayalolo Primary school. In conclusion, the Kato-Katz technique which is widely employed in STH/SCH parasiticdiagnosis alone cannot accurately detect infections. More accurate, simple and affordablediagnostics are needed to detect the infections in humans. This is having a major consequence indiseases control programmes. Though PCR techniques is expensive and required highly skilledpersonnel, its robustness and sensitiveness indicates it effectiveness in diseases surveillance,hence the need to develop affordable and field friendly PCR machines such as the MagneticInduction qPCR Cycler in endemic countries.

1258

THE HIGH POTENTIAL OF *BACILLUS THURINGIENSIS* DERIVED CRY5B AGAINST *STRONGYLOIDES STERCORALIS IN VITRO*

Sarit Charuchaibovorn[1], Vivornpun Sanprasert[2], Raffi V. Aroian[3], Surang Nuchprayoon[2]

[1]Lymphatic Filariasis and Tropical Medicine Research Unit, Chulalongkorn Medical Research Center (Chula MRC), Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [2]Department of Parasitology, and Lymphatic Filariasis and Tropical Medicine Research Unit, Chulalongkorn Medical Research Center (Chula MRC), Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [3]Program in Molecular Medicine University of Massachusetts Medical School, Worcester, MA, United States

Strongyloidiasis is one of the Neglected Tropical Diseases (NTDs). The disease has the global prevalence more than 100 million people and also causes a public health issues in livestock. Strongyloidiasis can cause a chronic infection, resulting in high mortality rates (69-87%), due to the autoinfection and dissemination of the parasites. Current anthelmintics for strongyloidiasis, including ivermectin (ivm) and albendazole (abz), still have disadvantages. Importantly, ivm-resistance has been found in *Strongyloides* spp. infecting livestock. This data suggests that ivm-resistance would be found in the major pathogenic species in humans, *Strongyloides stercoralis*. Consequently, the finding of new anthelmintics is still required. An interesting candidate is *Bacillus thuringiensis*-derived Crystal (Cry) protein named "Cry5B". The Cry5B has been demonstrated

the anthelmintic activity against a broad range of nematodes, especially on two main species of soil-transmitted helminthes (STHs), including *Ancylostoma ceylanicum* and *Ascaris suum*. Additionally, the Cry5B has been shown to be effective against abz-resistant and nicotinic acetylcholine receptor agonist-resistant *Caenorhabditis elegans*. We investigated the anthelmintic activities of the Cry5B against *S. stercoralis*, ivermectin-resistant (ivm^r), and albendazole-resistant (abz^r) *C. elegans*. Our findings demonstrated that the Cry5B was able to intoxicate the first larval stage (L1), infective stage (iL3), and adult free-living stage of *S. stercoralis*. Moreover, the Cry5B was active against ivm^r-*C. elegans*. The Cry5B impaired larval development, fertility, and viability of the worms. Interestingly, the Cry5B was more effective against ivm^r-*C. elegans* than wild-type *C. elegans*. The data showed that the Cry5B was highly effective against *S. stercoralis in vitro*. For the further investigations, we aim to demonstrate the effects of the Cry5B on the parasitic stage of *S. stercoralis* and the therapeutic efficacy in *S. stercoralis*-infected animals. We expected that the Cry5B can be used in treatment and transmission control of strongyloidiasis.

ELIMINATION OF THE SOIL TRANSMITTED HELMINTHS FROM GRENADA

Trevor P. Noël, Satesh Bidaisee, Paul J. Fields, Joanna Rayner, Rhonda Pinckney, Calum N. Macpherson

St. George's University, St. George, Grenada

The soil-transmitted helminths (STH) are present in all Latin American and Caribbean (LAC) countries, but the prevalence and intensity is unknown as only a few current national and subnational studies are available. The objectives of this study were to conduct a behavioral and intervention program and included: 1) Investigation of the prevalence of STH in Grenada and implementation of an elimination program; and 2) examination of the knowledge, attitudes, and practices among 9 and 10 year old students before and after the intervention. The intervention consisted of an educational presentation and a school STH poster campaign. Fresh stool samples from students were obtained and examined before and after the intervention. Automatic response systems (ARS) were used to assess short and long-term knowledge retainment of students over an eight-month period. Annual country level data (2006-17) on STH and feco-orally transmitted protozoan species were used to determine effects on national parasite prevalence. There was a positive significant short-term effect from the educational intervention on STH knowledge among the original 903 students. A long-term recall decrease in knowledge occurred in one out of eight questions (N= 767, p = 0.011). National STH baseline prevalence for school aged children in 2012 was 1.3% (7 of 527) and decreased significantly post intervention (0.0%) in 2014. STH prevalence among all ages significantly decreased from 0.77 to 0.25 % post-intervention, as did the prevalence of other protozoan species 9.83 to 5.92%. These data indicate that successful educational interventions can play a powerful role in the reduction of STH. Long-term knowledge retainment occurred and was attributed to the use of novel educational tools. This study demonstrated that the elimination of STH from a small island nation is feasible.

1260

A RANDOMIZED, DOUBLE BLIND, PLACEBO CONTROLLED TRIAL TO ASSESS EFECTIVENESS OF ALBENDAZOLE IN CHILDREN WITH ASYMPTOMATIC TOXOCARIASIS

Samanta Moroni, Guillermo Moscatelli, Nicolas Gonzalez, Griselda Ballering, Facundo Garcia Bournissen, Hector Freilij, Jaime Altcheh

Parasitology Service, "Ricardo Gutiérrez" Children Hospital and Multidisciplinary Institute for Research in Pediatric Diseases, Buenos Aires, Argentina

Human toxocariasis is highly prevalent and its global importance may be greatly underestimated. Toxocariasis occurs mainly in childhood by ingestion of parasite eggs from contaminated environment. During migration in human tissues the *Toxocara* larvae can cause several symptoms including eye involvement, but the majority of patients are asymptomatic. Eosinophilia is a marker of activity of this disease. There are no studies supporting the treatment of asymptomatic patients. To evaluate the effectiveness of albendazole (10-15 mg/kg/day BID for 15 days) a randomized, placebo-controlled trial was carried out in asymptomatic children (ClinicalTrials.gov #NCT00755560). Treatment response was defined as mean absolute reduction in eosinophil counts, 12 months after treatment. Demographic, complete blood count, liver and renal function and stool parasite exam were assessed at diagnosis, and every 4 months during follow up. Inclusion criteria: age 2 to 15 years, reactive toxocara excretory-secretory substances (TES) by ELISA, eosinophils >1100/mm3, normal fundoscopy and non geohelmintic infection.The 45 enrolled subjects, median age 5.3 years (range 2-13), were randomized in a 1: 1 relationship.At 12-month follow-up, eosinophil median was: 1008/mm^3 (IQ $_{25\text{-}75}$ 680 to 2023) in placebo group and median of 1360/mm^3 (IQ $_{25\text{-}75}$ 761 to 2226) in albendazole group (p = 0.37).Kinetics of specific antibody titers by the ELISA showed an erratic pattern. No differences were observed in the values between the 2 treatment groups. Both groups had minor adverse events and no patient needed to discontinue medication. In asymptomatic patients with toxocariasis, albendazole was not effective to reduce eosinophil counts. Given that toxocariasis is a neglected disease, in order to evaluate the effectiveness of albendazole or other drugs, further studies need to be conducted.

1261

MOLECULAR DETECTION OF *CAPILLARIA PHILIPPINENSIS* IN THE PHILIPPINES

Amalea Dulcene Nicolasora, Inez Andrea P. Medado, Karen Iana M. Cruz, Hannah Leah E. Morito, Allen Anthony P. Laraño, Deana Mae H. Ocampo, Neil Tristan M. Yabut, Francisco Gerardo M. Polotan, Lei Lanna M. Dancel, Dave A. Tangcalagan, Kim Joshua M. Dominguez, Rowena J. Capistrano, Sherwin A. Galit, Edelwisa S. Mercado

Research Institute for Tropical Medicine, Muntinlupa, Philippines

Intestinal capillariasis caused by *Capillaria philippinensis* (Cp) has been continually infecting Filipinos since its first detection in 1963 in the Philippines. The parasite is acquired from handling or eating raw or undercooked infected fish. Informing the public, especially those in remote provinces, about the dangers of capillariasis infection from consuming raw fish remains to be a challenge of the Philippines' Department of Health (DOH) in mitigating the disease. Another challenge is that the only current diagnostic method for this parasite in the country is through microscopic screening which has a low sensitivity and specificity. If left untreated, capillariasis can be fatal due to electrolyte depletion, cardiac arrhythmia and/or superimposed bacterial infections in patients. Thus, there is a need to develop or adapt a more reliable diagnostic method to confirm Cp infection. This study is the first to utilize nested PCR (nPCR) and Sanger sequencing to confirm Cp infection from an outbreak of diarrheal disease in a rural municipality in the Philippines. Samples (n=50) from patients suspected to have acquired Cp infection were analyzed using microscopy

and PCR. Results demonstrated a higher PCR detection rate of 14% as compared to the 2% positivity in microscopy. The nPCR assay limit of detection was determined to be at 10 DNA copies/µL. Therefore, the PCR assay utilized in the study is more sensitive than microscopy. 18S sequences (n=3) obtained herein clustered with *Paracapillaria philippinensis* (bootstrap value = 87) and *Baruscapillaria obsignata* (bootstrap value = 70), further confirming Cp detection and providing the first partial 18S sequences of Cp in the country since 1963. Thus, sequences from the multiple *Capillaria* genera used in the analysis clustered according to their genera with moderately high bootstrap values (*Bosmina longirostris* as an outgroup). The study suggests that molecular detection of parasitic infections such as that of Cp can be used as a confirmatory test or used in conjunction with microscopy screening to prevent misdiagnosis, provide guidance for treatment, and aid diarrheal outbreak investigations.

1262

CHARACTERIZATION OF CELL PHENOTYPES INVOLVED IN ASYMPTOMATIC HOOKWORM AND MALARIA PARASITE CO-INFECTIONS IN ENDEMIC GHANA

Dennis Adu-Gyasi[1], Seth Owusu-Agyei[2], Margaret Frempong[3], Dennis Konadu Gyasi[1], David Dosoo[1], Jones Opoku-Mensah[1], Rupert Delmini[1], Ben Gyan[4], Kwaku Poku Asante[1]

[1]Kintampo Health Research Centre, Kintampo North, Ghana, [2]Institute of Health Research, UHAS, Kintampo North, Ghana, [3]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [4]Noguchi Memorial Institute for Medical Research, Legon Accra, Accra, Ghana

IntroductionHookworm infections are associated with sources of poor drinking water, poor sanitation and poor hygiene. Malaria parasite infections also occur at places plagued by hookworms. We characterized cell phenotypes that are involved in the immune response to hookworm and malaria parasite co-infections in Ghana, West Africa.MethodCross-sectional community survey of 1826 participants randomly recruited at household level. Biological samples were collected over 12-month period. Flow cytometry analysis with labelled antibodies to cellular markers were used on selected peripheral blood mononuclear cell (PBMCs) to stimulate in culture to characterize the cell phenotypes present among those with hookworm and malaria parasite infections.ResultsCompared to those treated with no stimulation, PBMCs exposed to *Pf* parasitized RBCs in culture, revealed significant difference in the cell population for CD4+/IFN-γ+ (p=0.025), CD4+/Foxp3+/IFN-γ+ (p=0.016), CD4+/HLA-DR+ (p=0.019), CD4+/HLA-DR+/IL-4+ (p=0.032) and CD4+/HLA-DR+/IFN-γ+ (p=0.020). Significantly, CD4+/IFN-γ+ increased about twice among malaria infected individuals compared to other infection groups. CD4+/Foxp3+/IFN-γ+ cells were significantly higher in malaria infected individuals (p=0.016). CD4+/HLA-DR+/IFN-γ+ (p=0.020) and CD4+/HLA-DR+/IL-4+ (p=0.032) cells were higher in malaria infected individuals. CD8+/IFN-γ+ (p=0.029), CD8+/Foxp3+/IFN-γ+ (p=0.026), CD11c+/HLA-DR+/IFN-γ+ (p=0.031) and CD3+/TCR-γδ+ (p=0.026) were significantly different across infections. Discussion and ConclusionRegulatory T-cells population induced in the asymptomatic hookworm infection, malaria parasite infection and in their co-infected states were not significantly different. Hookworm infected individuals with malaria parasites co-infection significantly produce CD4+IL-4+ and CD8+Foxp3+IFN-γ+. In hookworm infections, Th2 effector cells are significantly different and cytotoxic T-cells are different among malaria infected people. There was also a significant increase in CD11c+/HLA-DR+/IL-4+ cells associated with hookworm infection.

1263

HELMINTHIC INFECTION IS ASSOCIATED WITH MALNUTRITION IN URBAN BANGLADESHI CHILDREN UNDER TWO YEARS OLD

Sultan Uz Zaman, Aleya Ferdous, Tuhinur Arju, Masud Alam, Rashidul Haque

International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

The first two years of life is a critical time period in infant development. When children in low-income settings start exploring their environment, they are exposed to soil-transmitted helminth (STH). A total of 490 children were recruited between January 2008 and June 2009. Children were followed for two years with household visits twice a week. Stool samples were collected once a month and all stool samples were examined using the Kato Katz technique. Length and weight were measured at baseline, at 12 months, and 24 months. 8.6% of the children had a STH infection by one year and 2.7% of these had STH ova identified on more than one occasion. 43.7 % of the children had a STH infection by 2 years, and 49.5% of these had a STH ova identified on more than one occasion. The mean age at first acquisition was 16.2 months (standard deviation (SD) 4.8 months). Microscopic examination revealed ova of *Ascaris lumbricoides* (0.6%), *Trichuris trichiura* (0.07%), and mixed infestation (0.02%) by one year but it was found higher *Ascaris lumbricoides* (3.6%), *T, trichiura* (0.7%), and mixed infestation (0.2%) by 2 years. About 26.5% children were underweight and 16.1% children were stunted at base line. At 12 months, 32.2% of children were underweight and 37.8% were stunted. At 24 months, 42.5% of children were underweight and 56.2% were stunted. STH infection in the first year of life was not associated with anthropometry at one year of age. *T. trichiura* infection during the first two years of life was associated with both stunting (P<0.02) and being underweight (P<0.03). *A. lumbricoides* infection was significantly associated with stunting (P<0.04), but not being underweight (P<0.2) by two years. In conclusion, in the first year of life STH infection is not associated with growth. However in the second year of life, preceeding STH infection is associated with both stunting (*T. trichiura* and *A. lumbricoides*) and being underweight (*T. trichiura*).

1264

CAPILLARIA OVA CONFOUND DIAGNOSIS OF *TRICHURIS TRICHIURA* IN HUMANS BY KATO KATZ SMEAR IN LIBERIA

Kerstin Fischer[1], Abakar Gankpala[2], Lincoln Gankpala[2], Fatorma K. Bolay[2], Kurt C. Curtis[1], Gary J. Weil[1], Peter U. Fischer[1]

[1]Washington University School of Medicine, St. Louis, MO, United States, [2]National Public Health Institute of Liberia, Charlesville, Liberia

Kato Katz smears are commonly used to detect and quantify ova of soil-transmitted helminths (STH). The barrel-shaped eggs of *Trichuris trichuria* are considered to be characteristic and easy to identify by microscopy. To assess the impact of mass drug administration (MDA) for the elimination of lymphatic filariasis (LF) on STH, stool samples were tested from Lofa and Maryland counties in Liberia. Duplicate Kato Katz smears from a single stool sample were examined for each participant. Aliquots of 578 randomly selected specimens were preserved on FTA cards or in RNAlater for analysis by qPCR. While qPCR confirmed the Kato Katz results from Maryland, its sensitivity was unexpectedly low for *T. trichiura* for samples from Lofa county: Twenty-seven samples (7.6%) were positive for *T. trichiura* by Kato Katz, but only 2 (0.6%) were positive by qPCR. qPCR-negative samples included 7 stools with more than 1,000 barrell-shaped eggs per gram. Therefore stool samples preserved in RNAlater were re-examined by microscopy with 100X and 400X magnification. Surprisingly qPCR-negative samples contained eggs with less pronounced plugs and a thick, striated egg shell. These features were consistent with eggs of *Capillaria* sp. (*Trichuridae*). Since human capillariasis has not been previously reported from Liberia we confirmed the presence of *Capillaria* sp. by PCR and DNA sequencing. Using conserved primers we were able to

amplify a 288 bp fragment of the 18S rDNA (GenBank MG859285) from samples that contained exclusively *Capillaria* eggs. Their DNA sequence was 100% identical to those of *Calodium hepaticum* (*C. hepatica*) (Genbank MF287972.1), *Aonchotheca putorii* (*C. putorii*) (Genbank LC052356.2) and *Pearsonema plica* (*C. plica*) (Genbank MF621034.1). While the life cycle and the medical importance of the *Capillaria* found in humans in Lofa remain to be elucidated, our results show that *Capillaria* eggs can easily be misidentified by Kato Katz as *T. trichiura*. *Capillaria* infection/pseudo-infection in known to be not affected by ivermectin and albendazole MDA which is used for LF elimination in Africa and qPCR is useful for validating Kato Katz results in STH surveys.

1265

NO EVIDENCE OF SOIL TRANSMITTED HELMINTH INFECTION IN A SURVEY OF STOOL SAMPLES FROM THE STATE OF MISSISSIPPI

Richard Bradbury[1], Irene Arguello[2], Meredith Lane[1], Sam Jameson[2], Kathryn Hellmann[2], Lisa Stempak[3], Regina Galloway[3], Sheryl Hand[4], Paul Byers[4], Susan P. Montgomery[1], Alfio Rausa[5], Brian Kirmse[2], Charlotte V. Hobbs[2]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Department of Pediatrics, University of Mississippi Medical Center, Jackson, MS, United States, [3]Department of Pathology, University of Mississippi Medical Center, Jackson, MS, United States, [4]Department of Health, Jackson, MS, United States, [5]Department of Health, Greenwood, MS, United States

Recent studies have highlighted a potentially unrecognized disease burden of soil-transmitted helminths (STH) in the American South. However, there have been no large-scale surveys conducted recently in Mississippi. We collected de-identified stool samples with corresponding subject age and zip code data from the clinical microbiology lab at the University of Mississippi Medical Center. Stool microscopy (saturated salt flotation) was used to identify evidence of STH infection. In parallel, real time PCR (as described previously) for *Necator americanus, Ancylostoma duodenale., Ascaris lumbricoides, Trichuris trichiura,* and *Strongyloides stercoralis* is being performed on DNA extracted from the stool samples. We evaluated 650 samples from 650 subjects [average age 52 (range, 3-91, median 56)]. Based on consistency/volume available, 522 were microscopically analyzed, and all were negative. 600 DNA extracts tested thus far for *Necator americanus* by real time PCR are negative. A further 254 samples that have been analyzed by PCR for *Ancylostoma duodenale*, *Ascaris lumbricoides, Trichuris trichiura,* and *Strongyloides stercoralis* have also yielded negative results. Analysis of the remaining DNA extracts ongoing. Data thus far suggests that prevalence of STH infection is low in this population. Further, larger studies of at-risk populations are indicated.

1266

STRONG TREAT 1 TO 4: A RANDOMIZED, OPEN-LABEL CLINICAL TRIAL ON MULTIPLE VERSUS SINGLE DOSE OF IVERMECTIN FOR THE TREATMENT OF STRONGYLOIDIASIS

Strongyloides stercoralis infection is a soil-transmitted helminthiasis with a wide distribution, primarily in tropical and subtropical regions. Most infected individuals are asymptomatic or have minor non specific symptoms. However, in the presence of immune suppression, strongyloidiasis can turn into a disseminated, life-threatening disease. Ivermectin is the drug of choice for treatment, but there is no consensus on the dosage regimen. Strong Treat trial is a multi-centre, randomized, open-label clinical trial conducted in a non-endemic area, where re-infection can be excluded. There are nine participating sites, in three European countries: Italy, Spain, and the United Kingdom. The Centre for Tropical Diseases in Negrar, Verona, Italy is the coordinating site. The aim of the trial is to compare the efficacy of two regimens of ivermectin for the treatment of strongyloidiasis: a single dose of 200 µg/kg versus 4 doses (200 µg/kg for 2 consecutive days, repeated two weeks apart). Baseline evaluation of the eligible patients included serology, fecal culture and/or PCR. The diagnostic criteria for inclusion were: either positive serology at "high titers" (according to pre-defined cutoff values) irrespective of the results of the fecal tests, or positive serology (irrespective of the value) and positive fecal tests. The enrolled patients were randomized into the two arms and followed up 6 and 12 months after treatment, with serology and fecal tests (the latter were repeated in case of positivity at baseline). Enrollment ceased in May 2017, with 311 patients included. An interim analysis on 194 patients with completed 12-month follow up showed high efficacy of both drug regimens, with no significant difference between the study arms. Final results are still pending (they will be presented at the annual meeting), but according to our projections they are most likely to confirm the data obtained from the interim analysis.

HOOKWORM INFECTION IN CHILDREN IS ASSOCIATED WITH NEGATIVE HEALTH OUTCOMES IN RURAL ALABAMA

Megan L. McKenna[1], Patricia E. Bryan[1], Catherine C. Flowers[2], Maria Elena Bottazzi[1], Peter J. Hotez[1], Rojelio Mejia[1]

[1]Baylor College of Medicine, Houston, TX, United States, [2]Alabama Center for Rural Enterprise, Lowndes County, AL, United States

Hookworm infection affects 430 million people, including 156 million children, worldwide and has been associated with anemia, iron deficiency, impaired cognitive development, and stunting in children. Hookworm, specifically *Necator americanus*, was known to be endemic in the southern United States before improvement of sewage disposal systems and eradication programs in more resource-poor areas. A recent study using modern molecular diagnostics revealed that, in high-risk environments with open sewage disposal systems in Lowndes County, Alabama, 34% of inhabitants tested positive for *Necator americanus*, with a low parasite burden. In addition, 60% of children in this study population also tested positive for hookworm infection. Given the preliminary findings, the lack of studies on low burden hookworm infection on health outcomes, a more in-depth study to evaluate prevalence and health impact of hookworm infection among children in high-risk, resource poor areas in the United States is desperately needed. A larger follow-up study is underway to determine the prevalence and disease burden of hookworm infection among children and soil in high-risk areas and the association of negative health impacts on children. Stool and blood samples will be collected from 334 children (2-12 years old) in high risk areas in Lowndes County, Alabama. The stool samples will be tested for hookworm using multi-parallel real-time quantitative PCR (qPCR) and blood samples will be tested for hemoglobin (Hb), iron, and markers of gastrointestinal injury (Intestinal fatty acid-binding protein [I-FABP]) and microbial translocation (soluble

CD14 [sCD14]). Soil near sewage run-off sites will be also be tested for evidence of hookworm by qPCR. This work is important in determining that soil-transmitted helminth infections are not only a problem in endemic countries, but in resource poor areas in the United States as well, and despite low burdens of infection, negative health outcomes could be affecting children within these resource-poor communities, prompting future study and intervention.

1268

CEREBROSPINAL FLUID NEOPTERIN AND CXCL13 ARE SUITABLE BIOMARKERS FOR STAGING AND DETECTION OF TREATMENT FAILURE IN A NON-HUMAN PRIMATE MODEL OF HUMAN AFRICAN TRYPANOSOMIASIS

Dawn Maranga[1], Maina Ngotho[2], Victor Mwadime[1], Thomas Adino[1], George Olouch[1], John Kagira[3], Maxwell Waema[3], Sylvain Bieler[4], Joseph Ndung'u[4]

[1]Institute of Primate Research, Nairobi, Kenya, [2]Mount Kenya University, Nairobi, Kenya, [3]Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya, [4]Foundation of Innovative and New Diagnostics, Geneva, Switzerland

Follow-up of treated human African trypanosomiasis (HAT) patients has been a routine practice for confirming cure and early detection of treatment failure. The aim of this study was to verify whether the neopterin and CXCL13 biomarkers are suitable for determining the stage of disease, and for monitoring the efficacy of treatment in a vervet monkey model of HAT. Six monkeys were infected with Trypanosoma brucei. Late stage disease was induced by sub-curative treatment with diminazene aceturate (DA) from 28 days' post-infection (dpi). When relapses occurred, the animals were treated curatively with melarsoprol (Mel B) from 82 dpi. Blood and cerebrospinal fluid (CSF) samples were collected at weekly intervals and assessed for parasitosis, as well as tested for neopterin and CXCL13 by ELISA, for a period of 39 weeks. The concentration of neopterin in serum increased rapidly after infection in early disease (stage 1), peaking at 14 dpi. Levels then dropped rapidly to pre-infection levels by 35 dpi. In contrast, there was a marginal increase in CSF neopterin during early infection, with a minor peak at 21 dpi. Serum CXCL13 increased rapidly from 7 dpi, peaking at 28 dpi, after which the levels dropped upon sub-curative treatment with DA. The concentration of CXCL13 in CSF also increased gradually in early stage disease and continued to rise after sub-curative treatment with DA. Curative treatment with Mel B resulted in its gradual decline, reaching pre-infection levels 105 days later. In conclusion, the changes in CSF neopterin and CXCL13 correspond to important time-points and stages of the disease. That peak levels coincided with time of relapses demonstrates the potential of these biomarkers in staging and detecting treatment failure. Moreover, the rapid fall in CSF neopterin after curative treatment confirms its great potential for use in development of a test of cure.

1269

ADDRESSING CHAGAS DISEASE AS PART OF PRIMARY CARE IN MASSACHUSETTS - THE STRONG HEARTS PROJECT

Jillian Davis[1], Jennifer Manne-Goehler[2], Juan Huanuco Perez[1], Katherine M. Collins[3], Natasha S. Hochberg[4], David H. Hamer[4], Elizabeth D. Barnett[5], Julia R. Kohler[6]

[1]East Boston Neighborhood Health Center, East Boston, MA, United States, [2]Beth Israel Deaconess Medical Center; Harvard Medical School, Boston, MA, United States, [3]Boston Children's Hospital, Boston, MA, United States, [4]Boston University School of Public Health; Boston University School of Medicine; Boston Medical Center, Boston, MA, United States, [5]Boston University School of Medicine; Boston Medical Center, Boston, MA, United States, [6]Harvard Medical School; Boston Children's Hospital, Boston, MA, United States

In Massachusetts, there are over 3,000 estimated cases of Chagas disease (CD). Immigrant communities at risk of CD often seek primary care in community health centers (CHCs). The Strong Hearts (Corazones Fuertes/Corações Fortes) program is a model to establish CD screening as a component of primary care for high-risk patients and to implement referral to specialists in tertiary hospitals for evaluation and antiparasitic treatment. The program also aims to educate medical professionals and community members, and to address barriers to care. In this study, we aim to describe the results of one year of screening. Among the screening tests with results available, 78 were initially positive with the Hemagen test and of these, 19 cases of CD were confirmed by the Centers for Disease Control using two different types of T. cruzi serologic assays. 11 (58%) of these 19 cases were detected in women, 3 of whom were pregnant; the average age of confirmed positive patients was 41 years, and 18 (95%) were from El Salvador. All 19 patients with confirmed CD were referred for specialty care, 13 (68%) have been evaluated and 3 (16%) have been started on antitrypanosomal therapy. One patient had already been treated for Chagas disease prior to this screening program. Treatment was deferred for the 3 pregnant patients until after they given birth. Moreover, inter-institutional care algorithms are being developed to follow infants of these mothers to test for congenital infection and, if present, provide antitrypanosomal therapy. While there are substantial barriers to care for communities affected by CD, the Strong Hearts program demonstrates that this disease can be addressed within primary care settings in the U.S.

1270

EVALUATION OF SAFETY AND EFFICACY OF *LEISHMANIA MAJOR* CENTRIN DELETED (*LMCEN-/-*) LIVE ATTENUATED PARASITES AS A PROPHYLACTIC VACCINE AGAINST VISCERAL LEISHMANIASIS

Subir Karmakar[1], Ranadhir Ranadhir Dey[1], Fabiano Oliveira[2], Nevien Ismail[1], Wenwei Zhang[3], Shinjiro Hamano[4], Greg Matlashewski[3], Abhay Satoskar[5], Shaden Kamhawi[2], Jesus G. Valenzuela[2], Hira L. Nakhasi[1]

[1]US Food and Drug Administration, Silver Spring, MD, United States, [2]National Institute of Allergy and Infectious Diseases, Rockville, MD, United States, [3]McGill University, Montreal, QC, Canada, [4]Nagasaki University, Nagasaki, Japan, [5]The Ohio State University, Columbus, OH, United States

Leishmaniases are vector-borne parasitic diseases affecting millions of peoples worldwide. To date there is no licensed vaccine available against human leishmaniasis. It has been shown that dermatotrophic *Leishmania major* confers protection against cutaneous leishmaniasis as well as against visceral leishmaniasis. However, such a method of immunization is not practical because of the greater risk of infection in a naïve population. Therefore, genetically modified live attenuated parasites that are non-pathogenic might induce the same protective immunity as leishmanization. We have developed centrin-gene deficient *Leishmania major (LmCen-/-)* using CRISPR-Cas methodology and evaluated the safety, immunogenicity as well as protective efficacy against *L. donovani* challenge. Golden syrian hamsters were immunized intradermally with *LmCen-/-* parasites in the presence or absence of the adjuvant GLA-SE. Intradermal immunization of hamsters with *LmCen-/-* did not develop any detectable lesion after immunization. *LmCen-/-* parasites alone is sufficient to induce a host protective immune response compared to *LmWT* infection. Seven weeks post-immunization hamsters were infected with *L. donovani* by needle injection or by infected sand flies. In both sets of experiments, nine months post-challenge, non-immunized hamsters developed severe pathology of VL, while immunized hamsters showed significantly lower parasite burden in liver and spleen compared to non-immunized animals. We also evaluated the cellular immune response between immunized & non-immunized hamsters after challenge with wild type parasites. Spleen cells from *LmCen-/-* immunized and challenged hamsters produced significantly more Th1-associated cytokines including IFN-γ and TNF-α, and significantly reduced expression of the anti-inflammatory cytokines IL-10 and IL-21, compared to non-immunized and challenged animals. The enhanced proinflammatory immune response correlates with lower

parasite in immunized animals. Our studies demonstrate that the *LmCen-/-* mutant parasite is safe and has a potential to be an effective vaccine against VL.

1271

EVALUATION OF POINT-OF-CARE TESTS FOR VISCERAL LEISHMANIASIS DIAGNOSIS IN KENYA

Margaret Mbuchi[1], Joseph M. Ndung'u[2], Monique Wasunna[3], Finnley Osuna[1], Charles G. Magiri[1], Alfred Muia[1], Peter Kioko[1], Michael Bakari[4], Frederick Mwathe[1], Ronald Ronoh[5], Edwin Abner[1], Mercy Chirchir[5], Simon Njenga[1], George Kirigi[1], Robert Kimutai[1], **Israel Cruz**[2]

[1]KEMRI, Nairobi, Kenya, [2]FIND, Geneva, Switzerland, [3]DNDi, Africa Regional Office, Nairobi, Kenya, [4]Kacheliba Sub-County Hospital, West Pokot, Kenya, [5]Kimalel Health Centre, Baringo County, Kenya

According to the Kenyan guidelines, the first approach for the laboratory diagnosis of visceral leishmaniasis (VL) is serology, testing VL suspects with rK39-based rapid diagnostic test (RDT) and direct agglutination test (DAT). Parasitological diagnosis, based on splenic aspiration microscopy (SAM), is invasive and is applied when antibody detection is useless: i) diagnosis of VL in seronegative suspects or in those with a previous VL episode, ii) test of cure and confirmation of relapses. Unfortunately rK39-RDTs have low sensitivity in eastern Africa, DAT is technically demanding and splenic aspiration presents the risk of bleeding, and requires technical expertise. This prompted us to assess whether an RDT based on the synthetic antigen rK28 (CTK Biotech, CA, USA) and a simple molecular test based on loop-mediated isothermal amplification (LAMP) to detect *Leishmania* DNA in blood (Eiken Chemical Co., Japan) could improve the current approach for VL diagnosis in Kenya. We recruited 133 VL suspects in two VL treatment centres in Baringo and West Pokot counties; 89 of them were classified as VL cases according to the clinical case definition: fever ≥ 2 weeks, splenomegaly or weight loss, and positive rK39-RDT, DAT or SAM. When blood and plasma from VL suspects were tested by rK39-RDT and rK28-RDT, both tests showed 100% specificity and similar sensitivity in blood (83.9% and 83.0% respectively), while rK28 RDT returned higher sensitivity (91.1%) than rK39-RDT (79.0%) in plasma samples. The most sensitive serological test was DAT using plasma (92.2%), with 100% specificity. SAM was more sensitive (82.9%) than LAMP (78.3%) and both were highly specific (100% and 96.9% respectively). The rK28-RDT was not superior to the current approach for serological diagnosis (rK39-RDT + DAT), but the sequential use of rK28-RDT in blood and, when this is negative, in plasma allows achieving a similar performance. LAMP did not perform better than SAM but this method may be preferred as it uses peripheral blood, and would allow reduction of the number of patients requiring splenic aspiration for parasitological confirmation.

1272

CHARACTERIZATION OF PREGNANT WOMEN WITH CHAGAS ASSISTING THE LABOR HOSPITAL OF PERCY BOLAND IN SANTA CRUZ, BOLIVIA

Freddy Tinajeros[1], Sarah Birk[2], Manuela Verástegui[3], Edith Malaga[3], Edward Valencia[3], Cristian Roca[1], Edith Hinojosa[1], Federico Urquizu[4], María del Carmen Menduiña[4], Robert Gilman[2]

[1]PRISMA, Santa Cruz, Plurinational State of Bolivia, [2]John Hopkins University, Baltimore, MD, United States, [3]Universidad Peruana Cayetano Heredia, Lima, Peru, [4]Maternidad Percy Boland, Ministerio de Salud Bolivia, Santa Cruz, Plurinational State of Bolivia

Chagas disease represents a serious public health problem due to its magnitude, transcendence, impact and challenges in disease control. The known area of dispersion of the main vector of Chagas disease in Bolivia covers approximately 60% of the territory, in geographical areas between 300 and 3000 meters above sea level. In different studies conducted between 2000 and 2017 in Bolivia, rates have been found between 19 and 29%. From May 2016 to March 2018, with the support of John Hopkins University and PRISMA, a prospective study was performed to screen for Chagas' in mothers and follow up their newborns. Mothers were given prior informed consent, InBios rapid tests for Chagas and HAI, the results of which could be available in under one hour. In addition, sociodemographic data and blood samples for ELISA were collected. Of the 5,420 mothers recruited, 19.2% had Chagas' disease. 67.3% were born in Santa Cruz, 16.5% came from Chuquisaca, 6.7% Cochabamba, 3.8% Potosí, 2.8% Tarija and 2.9% from other departments. The 37.1% were born in Andrés Ibáñez, 8.9% Cordillera, 3.2% Warnes, 2.2% Vallegrande and 1.75% Ichilo. In the study, 805 patients lived in urban areas with good living conditions, including in homes made with good materials, and not those commonly known to harbor triatomine. 11.43% of these patients had Chagas' disease. Among patients living in urban areas with good living conditions, 10.10% of those without mothers with Chagas' disease had Chagas. 23.17% of patients with Chagas-positive mothers living in urban areas with good living conditions also tested positive for Chagas. The odds of Chagas disease were over two and a half times higher in those with a Chagas-positive mother versus no Chagas-positive mother (OR: 2.69, 95%CI: 1.52-4.74, $p < 0.001$). In conclusion, the incorporation of the rapid test made it possible to speed up the detection of mothers with Chagas and subsequent follow up with their newborns. The women of Chuquisaca contributed a significant percentage of cases. It is important to ask pregnant women if their mother had Chagas, which shows a significant increased risk of exposure.

1273

DIAGNOSTIC PERFORMANCE OF A RECOMBINANT POLYMERASE AMPLIFICATION TEST LATERAL FLOW (RPA-LF) FOR CUTANEOUS LEISHMANIASIS IN COLOMBIA: A PILOT STUDY

Sandra Jimena Jojoa Jojoa[1], Alexandra Cossio Duque[1], Maria Del Mar Castro[1], Alejandro Castellanos Gonzalez[2], Peter Melby[2], Thomas Shelite[2], Nancy Gore Saravia[1], Bruno Travi[2]

[1]CIDEIM, Cali, Colombia, [2]Department of Internal Medicine-Infectious Diseases University of Texas Medical Branch, Galveston, TX, United States

Current diagnostic methods for cutaneous leishmaniasis (CL) are limited by the required technical expertise and invasive sampling, which hinders access to diagnosis in rural remote areas. Non-invasive sampling coupled to molecular parasite detection can improve access if they can be implemented in primary care facilities. This pilot study evaluated the performance of a Recombinant Polymerase Amplification Test - Lateral flow (RPA-LF) coupled to non-invasive sampling in Colombian patients. Patients ≥18 years of age with cutaneous lesions (>15 days duration) suggestive of CL were eligible. Samples were obtained from ulcerated skin lesions using the FTA Whatman paper. The sensitivity of the test was estimated against two gold standards: conventional diagnostic methods (smear/culture) and qPCR targeting the 18S rDNA. Twenty patients from the Colombian Pacific Coast with suspected CL were included. Age ranged from 22 to 62 years (Median: 35 years old). Among them, 17 were confirmed cases by conventional methods and qPCR. Median duration of disease was 2 months (range: <1-6 months since the appearance of the first lesion). *Leishmania* species were identified in 65% (11/17) of the confirmed cases: 73% were *L.V. panamensis* (8/11) and 27% *L. V. braziliensis* (3/11). The sensitivity of the RPA-LF test compared to standard diagnostic methods (smear and/or culture) and qPCR was 100% (95% CI: 80.5 - 100). The RPA-LF isothermal amplification test coupled to non-invasive sampling could facilitate access to diagnosis in remote settings where CL occurs. These results provide bases for a larger study to assess field performance and scale-up of this diagnostic method.

1274

THE REALITIES OF DIAGNOSING VISCERAL LEISHMANIASIS (VL) IN ENDEMIC AREAS OF GADARIF, SUDAN: A MIXED METHODS STUDY

Temmy Sunyoto[1], Gamal Adam[2], Atia Atia[2], Margriet den Boer[3], Koert Ritmeijer[4], Gabriel Alcoba[5], Albert Picado[6], Marleen Boelaert[1]

[1]Institute of Tropical Medicine, Antwerpen, Belgium, [2]University of al Qadarif, al Qadarif, Sudan, [3]MSF, London, United Kingdom, [4]MSF, Amsterdam, Netherlands, [5]MSF, Geneva, Switzerland, [6]FIND, Geneva, Switzerland

Visceral leishmaniasis (VL) is a lethal parasitic disease caused by Leishmania sp parasites, leading to 20,000 - 30,000 deaths annually. Correctly diagnosing VL is crucial, as its signs and symptoms L are not specific enough to differentiate the condition from other diseases causing persistent fever. Ideal VL test is highly sensitive, as VL is potentially fatal, and it should also be specific, as empirical treatment needs toxic, injectable drugs. Current invasive microscopic methods are unsuitable for settings with limited resources. Since the rollout of Rapid Diagnostic Test (RDT) in the Sudan leishmaniasis control program, their real value in clinical practice was never evaluated. The clinicians' adherence to current guidelines of clinical case definition and RDT in VL is critical, yet it never been documented. We aim to understand factors affecting adherence to diagnostic guidelines in Gadarif state, the VL hotspot in Sudan. We will conduct a mixed method study in purposively sampled four public hospitals. We collect qualitative data from in-depth interviews using semi-structured questionnaire, to study the perspective of health workers in the public and private sector on the diagnostic process for VL (awareness, opinions on feasibility, user-friendliness, relevance). We will document the adherence of health workers in the public and private sector to the current diagnostic guidelines, in particular to the clinical case definition and the use of RDT. We will analyze routinely collected data (lab register, patient registration, and medical records) in the study sites combined with exit interview for VL patients already discharged. The data collection will start in May 2018, and the results are expected to be ready by August 2018. Our results would help inform policy-makers and stakeholders on how best to adapt the diagnostic strategy in VL control in their diverse settings.

1275

POPULATION PHARMACOKINETIC OF BENZNIDAZOLE, A DRUG FOR CHAGAS DISEASE, IN AN ACUTE INFECTION MURINE MODEL

Daniela Rocco, Ernesto Gulín, Samanta Moroni, Jaime Altcheh, Facundo Garcia Bournissen

Buenos Aires Children's Hospital. Multidisciplinary Institute for Research in Pediatric Diseases (IMIPP), Buenos Aires, Argentina

Chagas disease, caused by Trypanosoma cruzi, affects an estimated of 8 million people in the world. Benznidazole, one of the only two drugs with proven efficacy, lacks important information on metabolism, specifically pharmacokinetics in both humans and animal models.The objective of this study was to evaluate the pharmacokinetics of benznidazole in a murine model of Chagas disease. A total of 28 male, 2 months old, BALB/C mice (16 infected, 12 healthy controls) were administered a single dose of 100 mg/kg benznidazole by gavage and blood was sampled by submandibular puncture at 0.25, 0.5, 1, 1.5, 2, 3, 4, 6, 8 and 24 hours. Mice were infected (N=16) by intraperitoneal inoculation with 500 parasites, VD strain, and treated when parasites were detected in blood circulation (15 days post infection). Blood was obtained from every animal (infected and healthy) at least twice and in some cases three times. Blood samples were centrifuged, and serum was precipitated with acetonitrile (1:1) and conserved at -70C until measurement by UHPLC-MS/MS. A population pharmacokinetics model was implemented with Monolix software (Lixsoft). Population pharmacockinetics followed a one compartment model. The maximum observed concentration was 67.7 µg/ml (Tmax 0.5 h). Absorption was fast (absorption constant ka $3.3h^{-1}$), volume of distribution was 29.9 ml and clearance 16.2ml/h (half life 2hs). No significant differences between infected and healthy animals were observed. We observed conserved pharmacokinetics behavior of benznidazole in infected animals compared to healthy mice, providing reassurance that concentrations obtained in this model reflect those required for drug effectiveness. Elimination of the drug was fast, suggesting that once daily dosing may be insufficient to sustain tissue concentrations required to sterilize the animals (but also confirming the lasting impact of benznidazole on the parasite, as beznidazole concentrations are expected to be low during most of the day with daily dosing).

1276

COMPREHENSIVE CONTROL OF CHAGAS DISEASE IN ENDEMIC RURAL AREAS FROM THE ARGENTINEAN CHACO - IMPACT ON DIAGNOSIS AND TREATMENT COVERAGE

Lorena Ruiz Cobo[1], Yanina Maza[1], **Diego Weinberg**[2], Ana Beltramone[3], Estela Calderón[3], Daniel Acuña[1], Marcelo Torres Perez[1], Mariela Fabiani[1], Marcelo C. Abril[2], Paula Sartor[1]

[1]Ministerio de Salud Pública, Chaco, Argentina, [2]Fundación Mundo Sano, Ciudad de Buenos Aires, Argentina, [3]Ministerio de Salud de la Nación, Ciudad de Buenos Aires, Argentina

The Municipality of Quitilipi (Chaco, Argentina) is located in the Gran Chaco Ecoregion, recognized as a hotspot for Chagas Disease (ChD) and other Neglected Tropical Diseases (NTDs). It is composed of 2,188 rural houses inhabited by 17,982 people, most of them creoles although there are some residents that belong to the Qom ethnicity. Up to 2014, diagnosis of ChD was performed either by demand or by family antecedents by the local health teams. This strategy allowed, during that same year, the study of 105 individuals under the age of 20 of which 26 were seropositive for ChD and 19 received etiological treatment. In 2015, entomological control actions with pyrethroids were initiated in 2,045 houses (93.4% coverage), with a global infestation rate of 13.9%, range of 3.9% to 44.4% between the different localities. Subsequently, community meetings and serological screening were performed in school and health posts. A total of 1,015 individuals were screened in 2015, 894 individuals in 2016 and 842 individuals in 2017 with seroprevalences of 26.1%, 12.4% and 12.9%, respectively. Starting in 2015, residents with positive serology were included in a treatment program conducted by medical teams in the rural area. In 2015, 108 individuals under the age of 20 were treated, 118 in 2016 and 65 in 2017, thus clearly increasing the number of treatments conducted in 2014 (n=19). Finally, interviews were held with community leaders and health professionals from two rural localities, La Pampita and La Matanza, in order to understand the success of the program. The articulation of the institutions with the community showed to awaken and sustain greater interest in the inhabitants while the discontinuity of the field actions by the different institutions generated less community interest and increases de disbelief of future actions. These results show that control actions carried out with institutional and community support, coupled with a comprehensive approach that integrates entomological and epidemiological aspects, tend to improve the coverage of diagnosis and treatment of ChD in an efficient and sustainable manner.

1277

IDENTIFICATION OF NOVEL ANTI-LEISHMANIAL COMPOUNDS AND THEIR EFFICACY ACROSS NINE *LEISHMANIA* STRAINS

Erica Penn, Mozna Khraiwesh, Richard Sciotti, Juan Mendez, Chad Black, Mara Kreishman-Deitrick, Mark Hickman, Jangwoo Lee, Brian Vesely

Walter Reed Army Institute of Research, Silver Spring, MD, United States

Leishmaniasis is a neglected vector-borne tropical disease caused by a protozoan of the genus *Leishmania.* The clinical spectrum of leishmaniasis ranges from self-healing cutaneous lesions (papules or ulcers) to irreparable damage of the soft and cartilaginous tissues and even to fatal systemic illness. Most of the drugs available today are difficult to use, have significant side effects, and have variable efficacy. Consequently, there is a search for safer, less expensive and more effective drugs. Known anti-leishmanial compounds such as Miltefosine have species-specific efficacy, while drugs such as Ambisome have potent efficacy across a wide range of *Leishmania* species. It is important to screen anti-leishmanial hits against a wide panel of leishmanial species early in a drug discovery program. In an effort to find novel anti-leishmanial drugs, a high throughput screen on a wide range *Leishmania* species is needed to evaluate IC_{50} values on intracellular amastigotes. In this study, a pLEXSY-hyg based vector was used to generate *Leishmania* parasites that constitutively express the firefly luciferase gene, to allow for rapid, luminescence-based readout. Nine transgenic species (*L. major, L. guyanensis, L. infantum, L. mexicana, L. panamensis, L. donovani, L. amazonensis and L. peruviana*) were evaluated in comparison to their wild type counterparts in terms of fitness and characterized for their utility for use in a high throughput screening format. A screen was performed using a collection of 219 antibacterial compounds in which seventeen candidates were identified to have potent activity across the 9 different *Leishmania* species.

1278

CHARACTERIZATION OF *TRYPANOSOMA BRUCEI* 20S PROTEASOME INHIBITOR

Yen-Liang Chen[1], Srinivasa Rao[1], Sarah Williams[1], Rima Ketan Palkar[1], Amy Pei[1], Hok Sum Cheung[1], Li Tian[2], Hazel Koh[3], Vanessa Manoharan[3], Jan Jiricek[1]

[1]Novartis Institute for Tropical Diseases (NITD), Emeryville, CA, United States, [2]Novartis Institutes for BioMedical Research, Shanghai, China, [3]Novartis Institute for Tropical Diseases (NITD), Singapore, Singapore

Phenotypic screening resulted in identification of triazolopyrimidine (TP) class of inhibitors that are active against all kinetoplastids. Resistant *Trypanosoma cruzi* parasites were generated against this compound class resulted in identification of F24L and I29M mutations β4 subunit of 20S proteasome responsible for this phenotype. These residues (F24 and I29) are conserved in all three kinetoplastids but not in humans, and ectopic expression of F24L or β4 I29M mutants alone in Trypanosoma brucei resulted in significant shift against the TP series of compounds. We have developed a homology model by using human 20S proteasome as template (PDB: 4R67). Using this homology model, additional contacts with b5 subunits were identified such as Y113 and G129. The model greatly facilitates the structural guided drug design to improve physchem properties while preserving on-target activity. Further investigation using genetics, biochemical and structural means are being pursued.

1279

CELLULAR AND HUMORAL IMMUNE RESPONSES TO *TRYPANOSOMA CRUZI* AFTER COMPLETE OR INCOMPLETE TREATMENT SCHEDULES WITH BENZNIDAZOLE

Melisa D. Castro Eiro[1], Maria G. Alvarez[2], Rodolfo Viotti[2], Huifeng Shen[3], Graciela Bertocchi[2], Bruno Lococo[2], G. Cesar[1], Maria A. Natale[1], Maria C. Albareda[1], Rick Tarleton[4], Susana Laucella[1]

[1]Instituto Nacional de Parasitología, Buenos Aires, Argentina, [2]Hospital Interzonal General de Agudos Eva Perón, San Martín - Buenos Aires, Argentina, [3]Center for Tropical and Emerging Global Diseases, Athens, GA, United States, [4]Center for Tropical and Emerging Global Diseases, University of Georgia, Athens, GA, United States

Chagas disease is the main cause of infectious myocarditis in the world. Benznidazole treatment for the chronic phase of Chagas disease is suspended in 17-30 percent of the cases mainly due to the appearance of severe dermatitis. We have previously shown that conversion to negative serology can be achieved after incomplete schedule with benznidazole raising the question of whether incomplete treatment may still be effective. The aim of this study was to perform a close monitoring of the changes of *T. cruzi* specific antibodies by a Luminex-based multiplex assay and the polyfunctional capacity of specific T cells by multiparameter flow cytometry after shortened treatment schedules with benznidazole. Multiplex assay was conducted in 11 patients with incomplete treatment schedule (7-25 days of treatment) and compared with 14 patients with full dose schedule with at least 36 months of follow up. Both patient groups had significantly decreased the mean fluorescence intensity of at least one protein at 36 months post treatment and had similar percentages of declining antibodies at 72 months of follow up (i.e., 9 out of 11 patients with incomplete and 14 out of 14 patients with complete schedule). An enrichment of IL-2-producing cells indicating a cessation of antigen stimulation was observed in both groups with complete and incomplete treatment schedules. Likewise, phenotyping analysis of IL-7R, CCR7, CD62L and activation marker HLAD-R in CD4+ and CD8+ T cells showed similar changes after complete or incomplete treatment. These findings strengthen our previous results showing that even shorter schedules of treatment with benznidazole can reduce antigen-induced alterations in T-cells.

1280

SURFACE GLYCOCONJUGATES FROM *LEISHMANIA MAJOR* AND *L. TROPICA* AS TARGETS FOR HUMAN HOST IMMUNE RESPONSE

Victoria M. Austin[1], Krishanthi Subramaniam[1], Alba L. Montoya[2], Nate Schocker[2], Katja Michaels[2], Igor C. Almeida[2], Alvaro Acosta Serrano[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]University of Texas, El Paso, TX, United States

Surface glycans have wide ranging importance in cell biology, including in recognition of invading pathogens by the human host. The dense glycocalyx of the *Leishmania* parasite protects the it from destruction by host factors, as well as presenting targets for antibodies to bind. During human infection, anti-glycan antibody levels increase, specifically those that can recognise terminal α-galactosyl residues. The structures responsible for this increase are not known, although a likely candidate is a family of glycoinositolphospholipid (GIPLs), which are one of the most abundant *Leishmania* glycoconjugates. As the glycan profile of GIPLs varies across *Leishmania* species, the possibility of selecting species-specific glycan-based biomarkers increases, which would improve diagnosis and aid the selection of appropriate chemotherapies. We have previously reported the identification of biomarkers of infection for Old World Cutaneous Leishmaniasis using a library of synthetic neoglycoproteins, which are recognised by sera from patients infected with either *L. major*

or *L. tropica*. Building on this work, we have now used a 1) structural glycobiology approach (i.e. thin layer chromatography (TLC) and mass spectrometry analyses of *Leishmania* glycolipids) and 2) screening novel glycan microarrays using sera from infected patients, to identify novel and species-specific α-galactosylated structures. Furthermore, initial imaging results indicate that α-galactosylated glycoconjugates may be secreted by *L. major* amastigotes during development within macrophages. Subsequent immunofluorescent imaging will investigate further the localisation of antigenic glycoconjugates throughout the parasite lifecycle.

1281

INVOLVEMENT OF THE NON-INFLAMMASOME FORMING NUCLEOTIDE-BINDING DOMAIN LEUCINE-RICH REPEAT PROTEIN 12 (NLRP12) IN MURINE VISCERAL LEISHMANIASIS (VL)

Diogo Valadares

University of Iowa, Iowa City, IA, United States

Leishmania infantum (Li) [MEW1] causes VL, with suppression of type 1 immune responses. The NLR proteins include >20 cytosolic proteins that regulate inflammation and immunity. Activation of three NLRs can cause assembly of an inflammasome leading to IL-1β and IL-18 release. Functions of non-inflammasome forming NLRs are not as well understood. We hypothesized that NLR proteins influence the course of VL by modifying the localized inflammatory response to *Li*. We screened for NLR effects by infecting NLR pathway gene knockout or wild type (WT) mice with *Li* coexpressing luciferase and mCherry. Progressive parasite expansion was monitored by *in vivo* imaging, qPCR and Luciferase assay. The screens suggested involvement of the non-inflammasome forming Nlrp12 in progression of VL. Parasite loads expanded early but were controlled in WT mice, whereas *Li* continued to expand and were 2-fold higher than WT on day 56 of *Nlrp12*$^{-/-}$ infection. Consistently, liver-derived infiltrating cells from *Nlrp12*$^{-/-}$ mice released less antigen-induced IFN-γ than WT cells on infection day 56. Flow Cytometry showed infl. monocytes expanded on day 28 in WT but not *Nlrp12-/-* mice, preceding clearance from WT. Instead, resident Mø expanded in *Nlrp12-/-* mice in parallel with the late expanding parasite load (day 56). The kinetics of monocyte derived DC (MNDC) recruitment paralleled parasite load, with recruitment at 28 days in WT but recruitment at 56 days in *Nlrp12-/-* mice. Both *in vitro* and *in vivo* migration studies showed an intrinsic DC migration defect in NLRP12 KO cells, while the gene expression for chemokines CCL-21, CXCL-12 and CCL-19 remains at same level as WT spleens. Surface expression analysis showed that DCs nlrp12-/- have reduced CXCR4 and CCR7 expression, which could explain the diminished migratory capacity. These data suggest that Nlrp12 plays a protective role in VL, associated with recruitment of both inflammatory monocytes and MNDCs at the time of peak parasite growth, followed by parasite clearance. DC infiltration in lymphoid tissue is impaired in the absence of Nlrp12, leading to delayed MNDC influx and impaired IFN-γ which permit parasite growth.

1282

IMMUNE IMPACT OF TICK-BORNE CO-INFECTIONS ON CANINE LEISHMANIASIS

Breanna M. Scorza, Angela Toepp, Kurayi Mahachi, Christine A. Petersen

University of Iowa, Iowa City, IA, United States

Visceral leishmaniasis (VL), a zoonotic protozoal disease, kills an estimated 20,000 people annually (WHO, 2012). Dogs are the primary reservoir for parasite transmission to humans and clinical status correlates with infectiousness to sand fly vectors. Like in humans, progression from asymptomatic to symptomatic canine visceral leishmaniasis (CanL) is accompanied by loss of CD4$^+$ T cell responsiveness to *Leishmania* antigen. The molecular signals driving exhaustion in either species are poorly understood. Intriguingly, within a naturally infected cohort of 174 dogs with CanL, asymptomatic dogs were 9.9x more likely to progress to clinical leishmaniosis if seropositive for ≥2 tick-borne co-infections (TBCs) over a six-month study period (p=0.0071). In Brazil, where dogs are a predominant reservoir for human VL, 80% of dogs were found to be seropositive for at least one TBC. We hypothesize that TBCs cause acute systemic inflammation in *Leishmania*-infected asymptomatic dogs, which promotes T cell exhaustion and symptomatic CanL. To evaluate this hypothesis, Type 1 immunity (circulating CD4$^+$ and CD8$^+$ T cell proliferation, cytokine production, and inhibitory receptor expression in response to *Leishmania* antigen stimulation *ex vivo* and peripheral NK cell phenotypes) and clinical progression of CanL (positive blood PCR or serology and clinical signs of CanL) will be compared in *Leishmania infantum*-infected dogs seronegative or seropositive for tick-borne pathogens: *Anaplasma*, *Ehrlichia*, and/or *Borrelia spp*. These data may provide new targets to prevent disease progression in dogs or people already infected with *Leishmania* and decrease parasite transmission to people by decreasing canine reservoir host parasitemia.

1283

CYTOTOXIC ACTIVITY BY NK CELLS CONTRIBUTE TO PARASITE KILLING AND IMMUNOPATHOLOGY IN CUTANEOUS LEISHMANIASIS

Taís Campos[1], Camilla Sampaio[1], Paulo R.L. Machado[2], Phillip Scott[3], Edgar M. Carvalho[1], **Lucas P. Carvalho**[1]

[1]Instituto Gonçalo Moniz- Fiocruz, Salvador, Brazil, [2]Federal University of Bahia, Salvador, Brazil, [3]University of Pennsylvania, Philadelphia, PA, United States

Skin lesions in patients with *Leishmania braziliensis* infection has been associated with inflammation induced by CD8+ T cells cytotoxicity. Moreover, cytotoxicity by these cells does not contribute to parasite killing, but instead, mediates pathology. Meanwhile, the role of cytotoxicity by NK cells in cutaneous leishmaniasis (CL) is still poorly understood. Here, we observed that NK cells frequency was increased in peripheral blood from CL patients when compared to healthy subjects, and that NK cell subsets express more IFN-γ, TNF, Granzyme B and Perforin than CD8+ T cells. We also found that most of the cytotoxicity activity in CL lesions is performed by NK cells. Also, in CL lesions, Granzyme B and Perforin were associated with lesion size. Lastly, we observed that NK cells contribute to destruction of *L. braziliensis* parasites. Our data suggest that NK cells contribute to the control of parasite multiplication, but also induce inflammation and tissue damage.

1284

NEW BIOMARKERS FOR HUMAN ASYMPTOMATIC *LEISHMANIA INFANTUM* INFECTION

Ines Elakhal Naouar[1], Nancy Koles[1], Rupal Mody[2], Dutchabong Shaw[1], Daniel Bigley[3], Edgie Co[2], Jeffrey Sherwood[2], Selma Jeronimo[4], Naomi Aronson[1]

[1]Uniformed Services University, Bethesda, MD, United States, [2]William Beaumont Army Medical Center, El Paso, TX, United States, [3]DiLorenzo Tricare Health Clinic, Arlington, VA, United States, [4]Federal University of Rio Grande do Norte, Natal, Brazil

In our previous study assessing the prevalence of asymptomatic visceral leishmaniasis (AVL) in 200 Operation Iraqi Freedom (OIF) deployers during 2002-11, we showed that 20% of deployed subjects were infected, using molecular and immunological assays. New biomarkers capable of identifying asymptomatic *Leishmania infantum* infected individuals are necessary for pinpointing persons at risk for VL activation. Samples were obtained from 27 interferon gamma release assay (IGRA)+, 8 ELISA +, 2 polymerase chain reaction (PCR)+, 8 uninfected OIF deployers, and 9 never-traveled subjects in the AVL study. Soluble Leishmania antigen (SLA)-stimulated supernatants of peripheral blood cells were used to assess cytokine levels by Luminex™ assay (Cytokine 25-Plex Human Panel, Invitrogen). Serum parasite load was determined using a repeat region (REPL) target *Leishmania* PCR; as well C-reactive protein (CRP) levels were

tested using sera obtained both at time of enrollment (2016-17) and banked within 6 months post-deployment. Moreover, we tested the sera reactivity against SLA using Western Blot. Our results show that mean CRP levels (mg/ml) were 0.037 in AVL IGRA+, 0.038 in AVL ELISA+, and 0.054 in non-exposed control subjects (p=0.14). One of the 200 deployers had 5 parasites/ml measured with serum *L. infantum* PCR. MCP-1, CXCL9, and Interleukin (IL)-8 were detected at high levels. IL-8 levels were higher in AVL IGRA+ compared to AVL ELISA+ and control subjects (56, 0.6 and 0.35 mg/ml, p=0.0001). IL-8 was not detected in the AVL PCR+ group. We also identified antibodies directed against a 70 kDa antigen in some AVL ELISA+ participants. In conclusion, elevated CRP was not associated with AVL, some limited serum PCR and western blot observations should be corroborated with a larger sample size. These results show that IL-8 could be a robust candidate biomarker of immunity for assessing AVL; differentiating between AVL IGRA+ versus AVL ELISA+, AVL PCR+. IL-8 has a role in the recruitment and activation of immune cells during visceral leishmaniasis which is a likely mechanism underlying our findings.

1285

IMMUNOGENICITY OF CYTOMEGALOVIRUS VECTORED VACCINES FOR CHAGAS DISEASE

Liliana Villanueva[1], Daniel N. Streblow[2], Takeshi Ando[2], Christine Meyer[3], Eric Bruening[3], Maria E. Bottazzi[1], Peter J. Hotez[1], **Kathryn M. Jones**[1]

[1]Baylor College of Medicine and Texas Children's Hospital Center for Vaccine Development, Houston, TX, United States, [2]Vaccine and Gene Therapy Institute, Oregon Health and Science University, Beaverton, OR, United States, [3]Vir Biotechnology, Portland, OR, United States

Chagas disease, caused by infection with the protozoan parasite *Trypanosoma cruzi*, affects 6 to 7 million people worldwide. Chronic Chagasic Cardiomyopathy develops in up to 30% of chronically infected individuals and it is the leading cause of non-ischemic cardiomyopathy in Latin America. Anti-parasitic treatment during chronic infection has poor efficacy and does not prevent cardiac death, thus adjunctive therapies are urgently needed. In chronically infected individuals, robust parasite specific T_H1 immune responses correlate with reduced or absent cardiac disease, thus vaccines that induce robust T_H1 immune responses are an attractive option for adjunctive therapy. Amastigote surface protein 2 (ASP-2) is an efficacious vaccine antigen when delivered as cDNA or adenoviral vectored vaccines in mice. Cytomegalovirus-vectored vaccines induce robust T_H1 directed immune responses in mouse and primate models. The goal of this study was to evaluate immunogenicity of cytomegalovirus-vectored Chagas vaccines in mice. Naïve or chronically infected female C57BL/6 mice were vaccinated once with either wild type or replication deficient murine cytomegalovirus (MCMV) constructs containing ASP-2 antigen. Antigen specific IFNγ responses were measured from splenocytes by ELISpot and flow cytometry 3 months after vaccination. Both constructs induced robust antigen specific IFNγ producing cells in naïve mice. Vaccination of chronically infected mice with the wild type MCMV vector containing the ASP-2 antigen induced a significant increase in total antigen specific CD8+ cells. Further both the wild type and replication deficient MCMV vectors containing the ASP-2 antigen induced significantly increased antigen specific CD8+ IFNγ+ cells. These data indicate that CMV-vectored vaccines induce robust antigen specific T_H1 directed immune responses and can boost the immune response in the presence of chronic *T. cruzi* infection. This may translate to therapeutic efficacy against Chagas disease. Future studies will evaluate the efficacy of therapeutic vaccination with MCMV vectored vaccines against Chronic Chagasic cardiomyopathy.

1286

EFFECTS OF INSULIN-LIKE GROWTH FACTOR-I AND IL-4 ON *LEISHMANIA (L.) INFANTUM*-INFECTED HUMAN MACROPHAGES

Hiro Goto, Orlando R. Sevillano, Luiza C. Reis, Eduardo M. Ramos-Sanchez

Universidade de São Paulo, São Paulo, Brazil

In *Leishmania* infection non-specific factors influence the development of the infection. We have shown previously the role of insulin-like growth factor-I (IGF-I) as an effector element of IL-4 response *L. (L.) major*-infected murine macrophages. In the absence of IGF-I the parasite growth promoting effect of IL-4 was nullified. In *Leishmania infantum* infection responsible for visceral leishmaniasis the role of IL-4 is controversial and it is not clearly related to susceptibility. Thus we aimed to evaluate the role of IL-4 and its relationship with IGF-I in *L. (L.) infantum* infection using human macrophages. Human monocyte cell line THP-1 ($5x10^5$ cells) was infected with stationary phase *L. (L.) infantum* promastigotes (8 parasites/cell) under stimulation with recombinant IL-4 (20 ng/mL) and recombinant IGF-I (50 ng/ml) that were maintained for 24 and 48 hours. The parasitism was evaluated by light microscopy, the *Igf-I* mRNA expression was quantified by Real Time (qPCR), and nitric oxide (NO) by Griess method and, arginase (*Arg1*) by qPCR and arginase activation by urea production. The parasitism did not show any increase in the parasite number after 24 and 48 hours under IL-4 and IGF-I stimuli in contradiction to what is seen in *L. major* infection. NO production and arginase activity remained constant during experimental period. The *Arg1* mRNA expression and *Igf-I* mRNA expression increased during the infection but IL-4 and IGF-I stimuli had not changed these expressions. Knowing from the previous study that IGF-I is directly related to expression and activation of arginase mainly on *Leishmania* leading to increase in the parasitism and decrease in NO production our present findings with *L. infantum*-infected human macrophages suggest that neither cell nor parasite arginase are critical to parasite development. Further NO production present during experimental period is seemingly not harmful to the parasite. In *L. infantum* infection, the parasite growth promoting effect of IGF-I, different from that observed in other cutaneous species of *Leishmania*, may explain any evident participation of IL-4 in *L. infantum* infection development.

1287

EXPRESSION OF COSTIMULATORY MOLECULES DURING VISCERAL LEISHMANIASIS AND AFTER CLINICAL CURE

João Firmino Rodrigues-Neto, Leonardo Capistrano Ferreira, Selma Maria Bezerra Jeronimo

Federal University of Rio Grande do Norte, NATAL, Brazil

Visceral leishmaniasis (VL) is a parasitic disease caused mostly by *Leishmania infantum* or *L. donovani*. The clinical outcome of the infection is in part related to the immune response elicited by the pathogen. Costimulatory molecules provide the second signal necessary to initiate the immune response and can be used by the parasite leading to an anti-inflammatory profile. The aim of this work was to evaluate costimulators and ligands present in cells of people exposed to *L. infantum*. Principal Component Analysis (PCA) was performed based on flow cytometry data for costimulatory molecules expressed in lymphocytes and CD14+ monocytes, in whole blood samples, obtained from subjects with symptomatic VL (n=12), recovered VL (n=12) and healthy subjects from the Leishmania endemic area (n=8), in *ex vivo*, unstimulated or after soluble Leishmania antigen (SLA) stimulation. The first two components explained more than 50% of the variance (PC1 - 38% and PC2 - 18%). Variables CD4/CD28/OX40/ICOS (loading=-0.510) and CD8/CTLA4/OX40/ICOS (loading=-0.583) were the most important within PC1, whereas variables CD4/CTLA4/OX40/ICOS (loading=-0.510) and CD14/HLADR (loading=0.504) were the most important within PC2. The groups showed different profiles with regard the T-cell populations expressing multiple costimulatory molecules (*i.e.* CD4/CD28/OX40/ICOS; CD4/CTLA4/OX40/

ICOS; CD8/CD28/OX40/ICOS; CD8/CTLA4/OX40/ICOS), in *ex vivo* and *in vitro* conditions, and these variables were different among the groups (p=0.001). However, CD4 and CD8 lymphocytes, *ex vivo*, expressing single costimulators (CD28, CTLA4, OX40 and ICOS) showed similar profiles (p>0.05). The same was observed to monocytes CD14+ expressing CD80, ICOSL, CD40, HLADR and CD80/ICOSL simultaneously. Whereas, *in vitro* condition, CD28, CTLA4 and ICOS (in CD4 and CD8) from symptomatic VL showed a distinct profile of the other groups. Only CD14/CD80/ICOSL showed different profile between the groups in the same condition. In summary, T-cell populations expressing multiple co-stimulatory molecules are those that most contribute on explaining variability across groups evaluated.

1288

DROMEDARY CAMELS: GROWING ZOONOTIC DISEASE RISK AT THE HUMAN-LIVESTOCK-WILDLIFE INTERFACE

Sophie Zhu[1], Dawn Zimmerman[1], Sharon Deem[2]

[1]Smithsonian Conservation Biology Institute - Global Health Program, Washington, DC, United States, [2]St. Louis Zoo Institute for Conservation Medicine, St. Louis, MO, United States

Dromedary, or one-humped, camels (*Camelus dromedarius*) are an almost exclusively domesticated species that are common in arid areas as production animals for meat and milk. There are approximately 13 million dromedary camels in the world today, with heavy population concentrations in Africa and the Middle East. As a food animal and beast of burden, the hardiness of camels in arid regions means humans are often heavily dependent on camels as a stable protein source. Like other livestock, camels also carry and may transmit pathogens to humans. Such zoonotic disease transmission is a concern due to growing human populations, increasing demands for meat, lack of biosafety and biosecurity protocols in abattoirs and milking facilities, and increased interface with wildlife as camel herds become sympatric with these non-domestic species. Our review describes the major zoonotic diseases present in camels, their risk to humans, and recommendations to minimize spillover events. We conducted a literature review of camel-borne zoonotic diseases and found that the majority of journal articles focused on Middle Eastern respiratory syndrome (MERS), brucellosis, *Echinococcus granulosus*, and Rift Valley fever. The outbreaks of MERS in 2012-2016 and high case fatality have elicited an aggressive response from the research community in MERS related research. However, other camel-borne diseases such as *Yersinia pestis*, *Coxiella burnetii*, and Crimean-Congo hemorrhagic fever are just as important to include in surveillance efforts. Camel populations, particularly in sub-Saharan Africa, are increasing exponentially in number in response to prolonged droughts. Using Laikipia County in Kenya, where camel populations increased 835% over a 30-year period, we will show how increased camel numbers and subsequent land use change, coupled with an increased interface with dense, but declining wildlife populations, has created a hot spot for the risk of emerging infectious disease spillover.

1289

A GENERALIZABLE ONE HEALTH PATHWAY FOR THE CONTROL OF ZOONOTIC DISEASES

Ria R. Ghai[1], Grace W. Goryoka[1], Maria E. Negron[1], Ryan M. Wallace[1], Antonio R. Vierra[1], Trevor R. Shoemaker[1], James C. Kile[1], Sean V. Shadomy[2], Julie R. Sinclair[3], Stephanie J. Salyer[1], Casey Barton Behravesh[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Food and Agriculture Organization of the United Nations, Rome, Italy, [3]The World Organisation for Animal Health, Paris, France

Effectively controlling zoonotic diseases requires a One Health strategy that cross-cuts the disciplines of human, animal (both domestic and wildlife) and environmental health. In many countries, however, coordinating mechanisms that facilitate multi-sectoral collaboration are inadequate or lacking, which can severely limit country capacity to prevent and control zoonoses. Here we describe a framework that takes a One Health approach and is generalizable in application to the control of any zoonotic disease. Specifically, the framework includes three components. The first is a pathway that outlines a stepwise approach to managing zoonoses. This pathway includes four stages that guide a country through the process of zoonotic disease management: 1) establishing a list of prioritized diseases; 2) evaluating country capacity; 3) developing plans, protocols, and procedures to address priority diseases; and lastly, 4) monitoring and evaluating progress. The second component is a toolkit that compiles existing guidance documents and resources matched to the elements of the generalized pathway. The final component are vignettes of five frequently prioritized zoonoses (anthrax, brucellosis, zoonotic influenza viruses, rabies, and viral hemorrhagic fevers), which use schematics to illustrate recommended multi-sectoral surveillance and response strategies. This approach highlights the commonalities of following a One Health model to zoonotic disease management, while also providing specific recommendations for common zoonoses. Importantly, in compiling and arranging existing yet disparate guidance documents, this framework provides operational guidance, which enhances country-level capacity to prevent, detect, and respond to zoonotic disease threats.

1290

CYSTINET-AFRICA: A ONE-HEALTH NETWORK FIGHTING TAENIASIS/CYSTICERCOSIS IN SUB-SAHARAN AFRICA

Helena A. Ngowi, Cystinet- Africa

Sokoine University of Agriculture, Morogoro, United Republic of Tanzania

Taenia solium is the most important food-borne parasite globally. Sub-Saharan Africa is among the regions highly affected by this parasite, leading to significant human morbidities and agricultural losses. Cysticercosis Network of Sub-Saharan Africa (CYSTINET-Africa) is a one-health network fighting cysticercosis and taeniasis caused by *T. solium* (TSCT) in Sub-Saharan Africa through North-South and South-South collaboration in research and capacity building. The network consists of a multi-disciplinary team of six institutions, four in Africa (Sokoine University of Agriculture, Tanzania; National Institute for Medical Research, Tanzania; University of Zambia, Zambia; Eduardo Mondlane University, Mozambique) and two in Germany (both at the Technical University of Munich). This project started officially in October 2016 and will run for five years. The project aims at (1) Estimation of prevalence and co-infections of TSCT/neurocysticercosis (NCC) in large-scale community based studies in Tanzania, Mozambique and Zambia, (2) Evaluation of the pathomechanisms involved in the development of symptomatic NCC in immunocompetent and immunocompromised individuals as well as pathomechanisms involved in different treatment responses in people with symptomatic NCC on standard treatment in longitudinal studies in Tanzania and Mozambique, (3) Establishment of an experimental pig model for *T. solium* cysticercosis for human and veterinary research needs as well as investigation of pig breed susceptibility to *T. solium* in Zambia and (4) Development, evaluation and implementation of a locally adapted health education intervention package for the prevention and control of TSCT in Tanzania. Progress towards achieving the project objectives will be presented. CYSTINET-Africa will create impact by linking human, animal and community health with respect to zoonotic diseases at various levels in sub-Saharan Africa. A rapid expansion of this network and its activities as well as its linkage with similar initiatives are envisaged.

SEROCONVERSION OF BATS IN NORTHEAST INDIA TO FILOVIRUSES AND HENIPAVIRUSES

Pilot Dovih[1], Eric Laing[2], Dolyce Low[3], Ansil BR[1], Yihui Chen[3], Martin Linster[3], Christopher Broder[2], Gavin Smith[3], Uma Ramakrishnan[1], **Ian Hewitt Mendenhall**[3]

[1]National Centre for Biological Sciences, Bangalore, India, [2]Uniformed Services University of the Health Sciences, Bethesda, MD, United States, [3]Duke-NUS Medical School, Singapore, Singapore

Bushmeat is an integral part of protein acquisition of communities worldwide. This practice increases the wildlife-human interface and provides opportunities for spillover of zoonotic pathogens into human populations. In Northeast India, there are several groups that hunt wildlife and in the state of Nagaland, bats are a prized not only for their protein, but also for their medicinal value. Bats are important vertebrate reservoirs for several medically-important families of viruses, including the filoviruses (ebolaviruses and marburgviruses) and henipaviruses (Nipah virus and Hendra virus). Here we screen sera from three species of pteropodid bats (*Cynopterus brachyotis*, *Eonycteris spelaea*, and *Rousettus leschenaultii*) that were harvested in Nagaland. We assessed seroreactivity using a multiplex bead-based assay that has glycoproteins in their native state for eight filoviruses (the five species in the genus Ebolaviruses, Marburg virus, Ravn virus, and Lloviu virus) and for three paramyxoviruses (Nipah virus, Hendra virus and Kumasi virus). Our findings indicate that all three species of bats had individuals that were seropositive for the ebolaviruses, but not Reston virus or Marburg virus. Individuals were often cross-reactive for multiple filovirus glycoproteins. There were individual bats that were seropositive to the glycoproteins of Ravn virus and Lloviu virus. One *E. spelaea* bat was seropositive to Kumasi virus and all three species had individuals that appear to be seropositive to henipaviruses, often cross-reactive to Nipah virus and Hendra virus. Pools of kidney, spleen and lung were screened for filoviruses with a nested RT-PCR, but all were negative. These results corroborate with a serology study in bats from Singapore and with the discovery of novel filoviruses in China from *Rousettus* and *Eonycteris* bats. It is likely there is much undiscovered filovirus and paramyxovirus genetic diversity in bats and expands the current geographic range of filoviruses.

1292

DETECTING SPECIES-SPECIFIC FECAL CONTAMINATION USING MICROBIAL SOURCE TRACKING MARKERS: A VALIDATION STUDY IN THE PERUVIAN AMAZON

Francesca Schiaffino[1], Alexandra Lorentz[1], Nora Pisanic[1], Dixner Renjifo Trigoso[2], Mery Siguas Salas[2],Maribel Paredes Olortegui[2], Pablo Penataro Yori[1], Margaret N. Kosek[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Asociacion Benefica Prisma, Iquitos, Peru

Fecal contamination and exposure to enteric pathogens within public and domestic domains is a well-known source infection and associated diarrheal disease. Traditional microbiologic methods are not able to discern human from non-human fecal contamination. However, the use of Microbial Source Tracking (MST) offer us a possibility to do so. However, the discriminatory power of these markers is site specific, requiring a performance evaluation to determine the sensitivity and specificity of each marker. The functional capacity of the LA35, Pig2Bac and BacCan MST primers and probes in laboratory conditions will be tested using real time PCR. We will use gBlocks as synthetic controls for each assay (IDT). Standard curves will be developed using serial dilutions (3×10^1 - 3×10^8) of gene copies/mL of the gBlock. We will test cross-reactivity by examining fresh feces from humans, chickens, ducks, parakeets, pigeons, goats, buffalos, pigs, dogs, and cats (10 of each species). We will calculate the sensitivity and specificity of the markers, as well as the positive and negative predictive values, as well as calculate the mean and standard deviation of log10 gene/copies per gram of feces. We are currently analyzing data. Results will be ready for the 2018 ASTMH conference.

1293

PREVALENCE AND GENOTYPING OF *LEPTOSPIRA* CARRIAGE OF RODENTS IN SOUTHERN AND NORTHEASTERN THAILAND

Panadda Krairojananan

U.S. Army Medical Directorate-Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

We report data confirming that rodents serve as the primary natural reservoirs of pathogenic *Leptospira* causing leptospirosis. A total of 1,075 rodents collected from two regions known to have high incidences of human leptospirosis cases: Ranong in Southern and Sisaket in Northeast of Thailand. Rodent trapping was carried out in residential and around farming areas close to human habitation. *Leptospira* carriage was identified directly on kidney specimens from the trapped rodents using *lipL*32 real-time PCR and 16S rRNA sequence analysis. *Leptospira* isolation and genotyping were also performed for these rodent specimens. The *Leptospira* prevalence rate in rodents was 10 % (50/490) in Ranong and 1.7% (10/585) in Sisaket. We found rodents carrying *Leptospira interrogans* in both regions in the same proportion at 50% (25/50 in the South versus 5/10 in the Northeast). The proportion of *Leptospira borgpetersenii* carriage among rodents in the Northeast (5/10, 50%) is higher comparing to the South (18/50, 36%). The twelve strains isolated from rodents in Ranong were *L. interrogans*. The novel sequence types for all isolates were found by MLST analysis and separated into two characters. The first of eight isolates (66 %) exhibited a new combination of known alleles; while the other four additional isolates (33 %) were composed of putative novel allele sequences. *Rattus rattus* was the dominant carrier (80%) in both regions.

1294

BRUCELLOSIS AMONG PYREXIA OF UNKNOWN ORIGIN CASES IN AMSING JORABAT SUB-CENTRE, KAMRUP METRO, ASSAM, INDIA

Takujungla Jamir[1], Sahabuddin Ahmed Laskar[2], Vaishali Sarma[2]

[1]University Health Centre, Kohima, India, [2]State Integrated Disease Surveillance Programme, Guwahati, India

Globally, around 500,000 human brucellosis cases are reported every year. In India, burden of human brucellosis is likely underestimated because of limited laboratory capacity. We investigated to estimate brucellosis burden among pyrexia of unknown origin (PUO) patients attending Amsing Jorabat Sub-centre in Kamrup Metro, Assam, an area with 10% prevalence of animal brucellosis. We reviewed records of PUO patients attending Amsing Jorabat sub-centre from January 1 to October 31, 2014. We defined a case as brucella positive if Rose Bengal Plate Test (RBPT) or Serum Agglutination Test (SAT) or both were positive along with IgM or IgG positive. We reviewed records of routine animal surveillance by Assam Agriculture University to see if cases had brucella positive animals in their farms. We analysed data using EpiInfo 7.1. Among 46 PUO patients in 2014, 25 (54%) were Brucella positive. Median age of brucellosis patients was 33 years (range: 18-67 years). Among the 25 cases, 88% were males and 80% were dairy farmers. All 25 case-patients owned dairy farms or worked as farm attendants. Major presenting symptoms were arthralgia (68%), fever (48%) and night sweats (48%). Patients became ill mostly during March (28%) and July (24%). Most positive patients (68%) were from Shillongia village. All 25 case-patients were engaged in milking and 19 (76%) were engaged in handling abortus during birthing. Assam Agriculture University found at least one animal positive for Brucella spp in each farm with a case. We found over half of PUO cases were brucellosis

cases among dairy farm workers who had brucellosis positive animals in their farms. We recommend multisector coordination involving health and veterinary departments to improve surveillance and control of brucellosis.

1295

USING BEHAVIORAL AND SENTINEL SITE SURVEILLANCE TO ESTIMATE ACUTE LEPTOSPIROSIS PERIOD PREVALENCE IN NORTHERN TANZANIA

Michael J. Maze[1], Katrina J. Sharples[1], Kathryn J. Allan[2], Holly M. Biggs[3], Shama Cash-Goldwasser[4], Renee L. Galloway[5], William De Glanville[2], Jo E. Halliday[2], Rudovick R. Kazwala[6], Blandina T. Mmbaga[7], Venance P. Maro[7], Matthew P. Rubach[3], Sarah Cleaveland[2], John A. Crump[1]

[1]University of Otago, Dunedin, New Zealand, [2]University of Glasgow, Glasgow, United Kingdom, [3]Duke University, Durham, NC, United States, [4]Duke University Medical Centre, Durham, NC, United States, [5]US Centers for Disease Control and Prevention, Atlanta, GA, United States, [6]Sokoine University of Agriculture, Morogoro, United Republic of Tanzania, [7]Kilimanjaro Christian Medical Centre, Moshi, United Republic of Tanzania

Our understanding of the burden of human leptospirosis is hampered by few robust estimates of incidence and crude means of modelling data from sentinel sites to other locations. We sought to explore the use of cross-sectional community behavioural surveillance to estimate leptospirosis occurrence based on exposure to locally relevant risk factors. We previously identified leptospirosis risk factors through a case-control study among patients who attended hospital with fever at a sentinel site in Moshi, Tanzania. We also conducted a cross-sectional study among randomly selected livestock-owning community members from six districts in northern Tanzania: Hai, Longido, Monduli, Moshi Municipal, Moshi Rural and Rombo. We administered a standardised questionnaire to participants asking about leptospirosis risk factors and the presence of fever within the previous two weeks. We analysed results by district. We estimated the probability of leptospirosis within the previous two weeks by applying coefficients from the multivariable model of risk factors for leptospirosis derived from our sentinel site to cross-sectional study participants who had experienced fever. We recruited 286 community participants. The mean predicted probability (95% confidence interval) of leptospirosis among livestock owners in each district was: Hai District 0.8% (0.0-1.8%), Longido District 1.6% (1.2-2.1%), Monduli District 1.6% (1.2-2.0%), Moshi Rural District 0.4% (0.1-0.8%), Moshi Municipal District 0.6% (0.4-0.8%), and Rombo District 0.9% (0.0-1.9%). Assuming the risk factors for leptospirosis that we established among febrile patients in Moshi convey similar risk in different districts, the two-week period prevalence among livestock owners, and therefore leptospirosis incidence is likely to be higher in Monduli District and Longido District than in MoshiMunicipal District or Moshi Rural District. Given the challenges of identifying confirmed cases of human leptospirosis, this approach may provide a useful way of estimating human leptospirosis risk in communities where surveillance of cases is challenging.

1296

HABITAT FRAGMENTATION AND LAND-USE CHANGE AS DRIVERS OF YELLOW FEVER OUTBREAKS IN SOUTH AMERICA

Arran Hamlet, Neil Ferguson, Tini Garske

Imperial College London, London, United Kingdom

Yellow fever (YF) is an arbovirus of the family flaviviridae found in Africa and South America. In South America YF is transmitted in two cycles: a jungle cycle between non-human primates and sylvatic *Haemogogus* and *Sabethes* mosquitoes, and an urban cycle propagated by *Aedes aegypti*. Since 1942, nearly all YF cases in South America have been due to the sylvatic cycle. Habitat fragmentation and land use change have been shown to alter zoonotic disease transmission dynamics, though the link to YF has only been postulated. Here we investigate the role of land-use change and habitat fragmentation on the inter-annual occurrence of YF. We fitted a series of random forest and logistic regression models to YF occurrence at the first administrative division to time-series data (2003-2012) and averaged values over this period of a number of covariates measuring land-use, habitat fragmentation and climate. The best performing models were combined to produce a weighted time-series and static model. These were evaluated using a spatial block bootstrapping method. Both time-series and static weighted models had a high out-of-sample predictive ability (AUC = 0.92 and 0.94). The most influential covariates were habitat fragmentation, cropland, the change in cropland over time and forest cover. Cropland, along with forest cover, appeared to be protective against YF reports - however habitat fragmentation and increases in cropland from previous years heightened the risk. This highlights a transition period where the risk of sylvatic spillover is greatest, and suggests that increased habitat conversion and fragmentation will increase the risk of YF cases. These findings may help to explain Brazil's ongoing largest YF outbreak since records began which has occurred outside the traditional endemic zone, but in areas with increasing cropland and deforestation. Applications of these findings may guide proactive vaccination or surveillance in areas where the risk of YF will increase with land conversion. By guarding against the expansion of YF, this could reduce the risk of large scale outbreaks such as those seen recently in Brazil, Angola and Nigeria.

1297

SEROPREVALENCE OF BRUCELLOSIS AND ASSOCIATED RISK FACTORS IN HUMANS AND LIVESTOCK IN HOIMA, UGANDA

Ayako Wendy Fujita[1], Lawrence Mugisha[2], Michael Mahero[3], Shamilah Namusisi[4], Dominic Travis[3], David Boulware[5], Katey Pelican[3]

[1]University of Pittsburgh Medical Center, Pittsburgh, PA, United States, [2]Conservation & Ecosystem Health Alliance (CEHA); College of Veterinary Medicine, Animal Resources and Biosecurity, Makerere University, Kampala, Uganda, [3]Department of Veterinary Population Medicine, University of Minnesota, St. Paul, MN, United States, [4]Makerere University School of Public Health, Kampala, Uganda, [5]Division of Infectious Diseases and International Medicine, University of Minnesota, Minneapolis, MN, United States

Zoonoses such as brucellosis may be significant contributors to non-malarial febrile illness in sub-Saharan Africa. Persons presenting with an acute febrile illness are often empirically treated for malaria, and many cases never reach medical attention. We described the seroprevalence of brucellosis and associated risk factors for seropositivity among people and livestock in western, rural Uganda. This was a cross-sectional study to assess seroprevalence of *Brucella* in Hoima, Uganda. We used random sampling to select households within two distinct communities. We tested participants' serum for *Brucella* IgG by ELISA; in livestock we used Rose Bengal Test.We administered surveys to collect potential demographic risk factors. We enrolled 286 adults from 194 households and tested 77 cattle and 284 goats. Seroprevalence of *Brucella* among households was 6.7% (13/194; 95%CI: 3.6-11.2%); when equivocal results were included, this increased to 19.1% (37/194; 95%CI: 13.7-25.3%).). Seroprevalence in cattle was 7.8% (6/77). No goats tested positive. Of the 37 households with positive/equivocal results, 49% (18/37) reported fever in the prior year. Of those with prior fever, 44% reported diagnosis of malaria and 31% reported never having a final diagnosis. None of the behavioral risk factors, including farming practice or consumption of dairy products, were statistically significant. Interestingly, 90% of households denied consumption of local dairy products. *Brucella* seroprevalence in humans was comparable to other studies estimating 8-14% and correlated with cattle seroprevalence. Despite frequent reports of fevers, many never received a diagnosis or were diagnosed with malaria. We found no statistically significant risk factors associated with *Brucella* seropositivity; however, there were relatively low numbers of reported behaviors traditionally linked to brucellosis. Our findings suggest that brucellosis may

contribute to non-malarial febrile illness in Uganda and should remain on the differential for febrile illness, even if patients deny risk factors typically associated with *Brucella* transmission.

ACUTE RESPIRATORY INFECTION SURVEILLANCE IN A PHASE 2 PROSPECTIVE, COMMUNITY-BASED COHORT IN VIENTIANE, LAOS

Erica Harris[1], Hubert Endtz[2], Inthalaphone Keovichith[3], Phimpha Paboriboune[3], Nicolas Steenkeste[2], Paul Newton[4], Melina Messaoudi[2], Bruno Flaissier[2], David Dance[4], Valentina Sanchez Picot[2]

[1]U.S. Naval Medical Research Unit No. 2, FPO, AE, United States, [2]Fondation Mérieux, France, Lyon, France, [3]Center of Infectiology Christophe Mérieux of Laos, Vientiane, Lao People's Democratic Republic, [4]Laos Oxford University Mahosot Hospital Welcome Trust Research Unit, Laos, Vientiane, Lao People's Democratic Republic

Emerging and re-emerging infectious disease pathogens are a bane to public health in both developed and underdeveloped nations. Respiratory infections caused by emerging and re-emerging viruses are among the leading causes of morbidity across the globe. A prospective, community-based cohort study in Laos to elucidate Acute Respiratory Infections across 25 villages in Vientiane Province has been ongoing since 2013. Enrollment criteria include participants ages >6 months who have lived in the same village for at least six months. Active case detection for influenza-like (ILI) symptoms is obtained via weekly phone calls to participants' homes. Those reporting symptoms were visited at home during which demographics and symptoms were recorded and nasal pharyngeal swabs and throat swabs taken. Specimens were analyzed using Real-Time PCR detection for 24 respiratory pathogens. To date, a total of 1,070 households have been enrolled, 973 cases of ILI reported, and 543 visits performed. A majority of the samples (61.6%) were from female participants. Of 540 PCR results, 22 different disease pathogens were detected. The majority of pathogens detected were FluA (22.04%), followed by rhinovirus (20.19%), human metapneumovirus (13.33%), and *S. pneumoniae* (18.7%). Results of this study help characterize the incidence and burden of respiratory pathogens among villagers in Laos in a country that normally has a tropical environment. The disease trends reported in this study are difficult to attribute to seasonal changes in Vientiane Province as FluA was more common from July to October. ILI symptom significance in this population and location provide impetus to continue monitoring viral pathogens in Southeast Asia.

1299

USE OF PULSE OXIMETRY FOR DIAGNOSIS OF HYPOXEMIA AND MONITORING OF CHILDREN WITH PNEUMONIA: A DESCRIPTIVE STUDY FROM ETHIOPIA

Habtamu S. Tolla[1], Yigeremu Abebe Asemere[1], Alemayehu Birehanu Belete[1], Mekitew Letebo Abuto[1], Zinabie Feleke Fekadu[1], Dinkineh Bikila Woyesa[1], Felix Lam[2], Simret Amha[3], Yibeltal Mekonen Feyisa[3]

[1]Clinton Health Access Initiative, Addis Ababa, Ethiopia, [2]Clinton Health Access Initiative, Boston, MA, United States, [3]Federal Ministry of Health, Addis Ababa, Ethiopia

Pneumonia is a leading cause of mortality among children under-five in Ethiopia and globally. Hypoxemia, low oxygen concentration in the blood is a fatal condition associated with pneumonia and a strong predictor of mortality. Pulse oximetry is recommended for detecting hypoxemia though the extent of its use is unknown in Ethiopia. We conducted a study to assess how often pulse oximetry was used among children diagnosed with pneumonia in 14 Ethiopian public hospitals. The primary outcome of interest was documentation of an arterial blood oxygen saturation measurement at diagnosis and during routine patient monitoring among children admitted to the pediatric ward. Medical records of 443 children aged 0-59 months with a primary diagnosis of pneumonia and seen at the hospitals between February 1, 2016 and April 30, 2017 were randomly selected for review. Data collectors consisted of three individuals with post-graduate degrees and who are familiar with clinical services and documentation practices in the hospitals. A structured checklist was employed to gather data on the use of pulse oximetry. Data was entered using Epi Info and analyzed using SPSS. Out of the 443 charts reviewed, 245 (55.3%) were diagnosed with pneumonia while the remaining 198 (44.7%) had severe pneumonia. Forty four (10.2%) children had documented oxygen saturation measurements at diagnosis. None of the children seen at primary hospitals had pulse oximetry assessments at diagnosis. Thirty one (14.8%) and 14 (12.6%) children seen at general and referral hospitals, respectively, had oxygen saturation measurements at diagnosis. Thirty eight children (19.2%) with a diagnosis of severe pneumonia had pulse oximetry measured at diagnosis compared to 7 (2.9%) children with a diagnosis of non-severe pneumonia. Out of 196 children admitted to the pediatric wards, 87 (43.9%) had measurements of pulse oximetry for monitoring purposes. There is limited use of pulse oximetry for diagnosis of hypoxemia and patient monitoring in hospital settings in Ethiopia. Efforts to increase consistent use of pulse oximetry by health workers will be important to improve child survival in Ethiopia.

In August 2017, an urban pneumonic plague outbreak began in Madagascar. Pneumonic plague is caused by inhalation of *Yersinia pestis*, a gram-negative bacterium. It is classically described as presenting with abrupt onset of fever and rapid, fulminant, progression of respiratory symptoms. The clinical data on pneumonic plague is limited however, and predominantly based on retrospective case reports and small case series. Early in the outbreak there were reports of apparent atypical presentations, including patients presenting with prolonged duration of symptoms prior to admission. There were several potential reasons for this, including a more diverse clinical spectrum than that described in the literature, the use of antibiotics in the community, co-infection with other pathogens, and poor specificity of the F1 rapid antigen test (RAT) on sputum for diagnosing pneumonic plague. The main objectives of this prospective study therefore were to characterise the clinical presentation of patients admitted to pneumonic plague treatment centres, and identify factors associated with atypical presentations. All patients admitted to pneumonic plague treatment centres with a diagnosis of suspected pneumonic plague were eligible for inclusion. Clinical data was collected at admission and daily until discharge. The following laboratory tests were performed at admission: sputum culture; blood culture; sputum PCR and RAT for *Y.pestis*; blood PCR for *Y.pestis*; nasopharyngeal swab PCR for viral pathogens; urine and serum antibiotic levels (septrin, gentamicin, ciprofloxacin); CBC and CRP; *Y.pestis* serology (and at discharge). Patient recruitment started on the 2nd November 2017 and ended on the 31st of December 2017. Data from the study will be presented.

PREDICTORS OF *STREPTOCOCCUS PNEUMONIAE* CARRIAGE AND ESTIMATES OF PCV10 VACCINE EFFECTIVENESS IN RURAL PAKISTAN

M Imran Nisar[1], **Benjamin M. Althouse**[2], Fyezah Jehan[1], Sheraz Ahmed[1], Furqan Kabir[1], Sadia Shakoor[1], Asad Ali[1], Najeeha Iqbal[1], Hao Hu[2]

[1]Aga Khan University, Karachi, Pakistan, [2]Institute for Disease Modeling, Bellevue, WA, United States

Background and aimsKnowing predictors of S. pneumococcus (SP) carriage in developing settings is important for introduction of PCV. Further estimates of vaccine effectiveness against carriage in such settings is unknown. MethodsAn ongoing NP carriage survey near Karachi, Pakistan randomly selects 60 infants per month and gathers information on illness indicators, socioeconomic status, and household demographics. Multiple logistic regression models were fit to explore potential predictors of vaccine-type (VT) carriage as well as to estimate the vaccine efficacy in this setting. ResultsVT carriage was positively associated with having runny nose in the previous two weeks (OR: 1.893; 95% CI: 1.41-2.55). Factors negatively associated with VT carriage were: parental education >6 years and fever in the previous two weeks (OR: 0.348; 95% CI: 0.19-0.64, and 0.686; 95% CI: 0.51-0.93, respectively). Three doses of PCV10 showed a significant vaccine efficacy for VT carriage of 0.386 (95% CI: 0.08-0.59) adjusted for various demographic factors. ConclusionsPCV10 demonstrated efficacy for NP carriage in our model in rural Pakistan. As in similar settings, increased parental education was negatively associated with SP carriage, while symptoms (runny nose in the previous 2 weeks) was positively associated with carriage.

1302

ESTIMATION OF A PREDICTIVE FUNCTION FOR MMR VACCINATION BEHAVIOR AS A FUNCTION OF YEAR AND AGE

Sojung Koh, Alex Perkins

University of Notre Dame, Notre Dame, IN, United States

Measles is a highly contagious viral disease that can potentially cause pneumonia, encephalitis, and even death. Measles transmission is currently on the rise globally and is recently facing situations of lower rates of vaccination. If such low rates persist, the increasing number of unvaccinated individuals will lead to worsening outbreaks and could possibly even lead to the re-establishment of endemic measles if vaccine coverage deteriorates to a large enough extent. We developed a model designed to predict the probability an individual has received at least one dose of MMR vaccine as a function to their age, the current year, and their demographic characteristics. We formulated this model as a bivariate B-spline hazard function in two continuous dimensions: year and age. Refinements of this model that depend on demographic characteristics were explored, with particular demographic features used in the model being chosen on the basis of model selection with the Akaike information criterion. The model was fitted to three datasets published by the Centers for Disease Control and Prevention that reflect surveys carried out in a subset of the population for infants, toddlers, and teenagers, mostly at the state level, and stratified as a function of demographic characteristics. The model's geographical detail provided insight about which parts of the country might be more susceptible to outbreaks and in need of higher vaccination coverage. The model we developed has implications for estimation of vaccination coverage for measles and helps extract nuanced information about vaccination behavior from publically available data sources.

Pneumonia accounts for about 10-30% of childhood deaths in Uganda. Emerging resistance to antibiotics commonly used for treatment of bacterial pneumonia in Uganda is of concern. We report on the bacterial aetiology and their susceptibility profile, and mortality rates among children hospitalized with pneumonia. In 2016, an Acute Febrile Illness (AFI) sentinel surveillance programme started in the Paediatrics wards of six reference hospitals in Uganda including Jinja, Arua, Mubende, Kabale, Tororo, and Apac. All children ≤14 years with a history of fever or temperature ≥37.5˚C were tested for malaria by microscopy or rapid diagnostic test. Those with a negative malaria test result got a blood draw for culture. Samples were incubated in BACTEC machines at the hospitals. Positive samples were sent to a core laboratory at Makerere University for sub-culturing. Antimicrobial Susceptibility Testing (AST) was done using Kirby-Bauer disk diffusion method. Pneumonia was diagnosed using the Integrated Management of Childhood Illness (IMCI) guidelines. Between July 2016 and January 2018, 21,207 children were hospitalized. 4,429 (20.9%) of them had pneumonia as the primary diagnosis. 50% of children with a diagnosis of pneumonia were between 1 and 4 years of age, while 40% were below 1 year. Blood cultures were performed on 1,272 patients with pneumonia and 22 (1.7%) yielded a pathogen. Staphylococcus aureus (6, 27.3%), Salmonella species (5, 22.7%), and Streptococcus pneumoniae (3,13.6%) were the commonest bacteria associated with pneumonia cases. ceftriaxone (18.2%), gentamicin (40.8%), and ampicillin (22.3%) were the most commonly prescribed antibiotics for treatment of pneumonia. 66.7% of S. aureus organisms were sensitive to both oxacillin and gentamicin, whereas 33.3% of S. pneumoniae were sensitive to ceftriaxone. Salmonella spp were 80% sensitive to Ceftriaxone.The case fatality rate was 5.6%. A proportion of the bacteria showed resistance to commonly prescribed antibiotics. There is need to continue surveillance of the bacterial etiology of pneumonia and susceptibility patterns to commonly used antibiotics.

1304

EVALUATING CHANGES IN PNEUMONIA INCIDENCE AFTER TWENTY YEARS IN CHILDREN AGED 2-59 MONTHS IN OSHIKHANDASS, PAKISTAN: A COMMUNITY-BASED STUDY

Chelsea Hansen[1], Syed Iqbal Azam[2], Alexandra Jamison[1], Elizabeth D. Thomas[1], Ejaz Hussain[1], Julia Baker[1], Nahida Bano[2], Zeba Rasmussen[1]

[1]Division of International Epidemiology and Population Studies, Fogarty International Center, National Institutes of Health, Bethesda, MD, United States, [2]Aga Khan University Department of Community Health Sciences, Karachi, Pakistan

Pneumonia and diarrhea were the main causes of childhood mortality from 1989-1991 in Oshikhandass, a rural village in the Karakorum mountains of northeast Pakistan. Research Workers (RWs) trained in pneumonia management did weekly surveillance of children 2-59 months from 1992-1996 and again from 2012-2014 to evaluate changes in pneumonia incidence. RWs classified pneumonia cases by severity according to WHO Integrated Management of Childhood Illness criteria, gave treatment or referred, and followed-up until recovery. In the first study, 1252 children were followed for 2180 child-years (CY); 42.9% had at least one episode, and 7 children died from pneumonia. In the second study, 979 children were followed for 953 CY; 19.7% had at least one episode, and none died from pneumonia. Between the two study periods, the incidence of pneumonia decreased from 0.5 to 0.3 episodes/CY (RR: 0.6 second v. first study, 95% CI: 0.5-0.6), and prevalence decreased from 2.5 to 1.6 days of pneumonia/CY (RR:0.6, 95% CI: 0.6-0.7). The mean duration of illness before seeking care was consistent between the two studies at 2.4 days. From 1992-1996, 3.7% of pneumonia cases were severe and 1% were very severe (i.e. had danger signs per WHO criteria). In the second study, 3.6% were severe and no cases were very severe. Incidence was highest in children 2-5 months of age in the first study (0.9/CY, 95% CI: 0.7-1.0), and in children 6-11 months of age in the second study (0.5/CY, 95% CI: 0.3-0.6). In the first study 8.4% of children with pneumonia were reported to have prior use of antibiotics, with 5.5% of cases referred for additional care, 2.7% hospitalized, and 99% cured. In the second study 52.6% of children were reported to have prior antibiotic use, with 2.4% of cases referred and hospitalized, and 99.6% cured (0.4% lost to follow-up). In both studies the highest rates of pneumonia occurred in the winter months from November to March. Over the 20-year period, cure rates remained high, while incidence, prevalence and mortality decreased substantially between the two studies. Reasons for the decrease are being explored and could include introduction of HIB vaccine and improved SES.

1305

MODELING MEASLES IMPORTATION PATTERNS INTO THE UNITED STATES USING PUBLIC HEALTH SURVEILLANCE AND AIRLINE TRAVEL DATA

Marya Poterek, Alex Perkins

University of Notre Dame, Notre Dame, IN, United States

Despite the declared elimination of endemic measles in the United States in 2000, the number of measles cases and outbreaks in the United States has begun to rise in recent years, as measles-mumps-rubella (MMR) vaccination rates in the US are declining and transmission internationally is on the rise. Measles is a highly infectious illness that can cause symptoms such as high fever, acute rash, and even death in susceptible individuals. Cases imported to the US often result in outbreaks that affect vulnerable populations, including children who are too young to be vaccinated. The majority of these imported cases reach the US via international passenger air travel through major metropolitan hubs. Our goal was to use air travel data in conjunction with measles data reported by the World Health Organization at the country-level worldwide and state-level data on imported measles cases in the US to develop an explanatory model for patterns of measles importation into the US. We focused on using maximum likelihood to estimate numerical values for quantitative parameters that scale estimated risk of measles among international travelers arriving in the US to numbers of observed cases imported into the US. With these parameter estimates, we used our fitted model to establish country-specific importation probabilities and to document fluctuations in the relative probability of importation into the US from different countries over time. These estimates were found to have sufficient predictive capability to enable nowcasting of possible measles importation into the US on the basis of updated measles surveillance data from the WHO and to inform models of measles outbreak dynamics in the US.

ACUTE RESPIRATORY VIRAL INFECTIONS: AN IMPORTANT CAUSE OF ADMISSIONS FOR ACUTE FEBRILE ILLNESS IN THE SOUTHERN PROVINCE, SRI LANKA

L. Gayani Tillekeratne[1], Champica K. Bodinayake[2], Ryan Simmons[1], Ajith Nagahawatte[2], Vasantha Devasiri[2], Sky Vanderburg[1], Ruvini Kurukulasooriya[2], Bradly P. Nicholson[1], Larry P. Park[1], Truls Ostbye[1], Megan E. Reller[1], Christopher W. Woods[1]

[1]Duke University, Durham, NC, United States, [2]Faculty of Medicine, University of Ruhuna, Galle, Sri Lanka

Respiratory virus contribution to acute febrile illness (AFI) varies globally. The objective of this study was to determine the prevalence, etiology, and seasonality of viral respiratory illness among hospitalized AFI patients in Sri Lanka. We enrolled consecutive AFI patients ≥1 year admitted to the largest hospital in the Southern Province from Jun 2012-Oct 2014. We collected epidemiologic and clinical data and a nasal/nasopharyngeal sample and tested alternate samples using multiplex polymerase chain reaction (Luminex NxTAG Respiratory Pathogen Panel; 19 viruses, 3 bacteria). We determined correlation between weather data and the monthly proportion of respiratory viral AFI using the Spearman correlation. We assessed seasonality of respiratory viruses using a Program for Appropriate Technology definition (monthly positive cases divided by annual positive cases; 'peak' defined as monthly proportion ≥10% for two consecutive years). A total of 964 patients were enrolled; median age was 26.2 years (IQR 14.6- 39.9 years) and 646 (67.0%) were male. Approximately one-fifth (205, 21.3%) tested positive for a respiratory pathogen. The most common pathogen detected was influenza (134, 13.9% of all patients), with 9.1% having influenza A. Other viruses identified included human enterovirus/ rhinovirus (13, 1.4% of all patients), parainfluenza virus (13, 1.4%), respiratory syncytial virus (11, 1.1%), human metapneumovirus (11, 1.1%), and bocavirus (0.7%). Two patients had a bacterial respiratory pathogen (1 *Mycoplasma pneumoniae*, 1 *Chlamydophila pneumoniae*) and 7 (0.7%) had respiratory viral co-infections. The proportion of monthly respiratory viral cases was associated with maximum daily temperature (p=0.03) but not with minimum daily temperature, rainfall, or daytime or nighttime humidity. Respiratory virus and influenza positivity peaked in February- June of each year (excluding March). We identified respiratory viruses in a large proportion of patients admitted with AFI in southern Sri Lanka, with clear seasonality. Improved preventative efforts through targeted influenza vaccination may help reduce burden of illness.

1307

THE USE OF SMOKE BASED MOSQUITO PREVENTION METHODS: A RISK FACTOR FOR ACUTE RESPIRATORY INFECTIONS IN CHILDREN?

Nancy R. Stroupe[1], Jenna E. Coalson[1], Ellen M. Santos[1], Maurice Agawo[2], Kacey Ernst[1]

[1]University of Arizona, Tucson, AZ, United States, [2]Kenyan Medical Research Institute, Nairobi, Kenya

Globally, Acute Respiratory Infections (ARI) are a leading cause of morbidity and mortality among children <5 years of age. The majority of the ARI disease burden exists in the low income countries, with particularly high

mortality rates in sub-Saharan Africa. Exposure to indoor air pollution (IAP) is an established risk factor for ARI. Most research on IAP and respiratory health has focused on environmental tobacco smoke and cooking indoors with biofuel. The use of smoke-based mosquito prevention methods (ex. coils) has received little attention, despite the estimate that 40-50 billion mosquito coils are used annually by 2 billion people worldwide. To our knowledge, no studies investigating the association between mosquito prevention methods and respiratory health have been conducted in sub-Saharan Africa. Using data from a cross sectional survey conducted in high (>1500 m) and low (<1500 m) altitude sites in rural western Kenya, we investigate the relationship between smoke-based mosquito control measures (ex. mosquito coils) and ARI in children <12 years of age. Households completed detailed surveys on knowledge, attitudes and practices around malaria as well as illness prevalence among household members. The study sample consisted of 1,217 households with 1,669 children <12 years of age. ARI, defined in this study as the presence of a cough within 2 weeks of the survey, was present in 33% percent of children <12. Nine (9) percent of households reported using smoke-based mosquito control methods, 88% reported use of other methods (ex. bednets), and 2% reported using no methods. Significantly more lowland households used smoke-based methods than highland households (16% vs. 4%). There were no significant differences in ARI among children <12 between high and low altitude sites. Preliminary analyses suggest no significant difference in ARI between children in households using smoke based vs all other mosquito prevention methods (including none). However, prevalence of ARI was quite high compared with national averages, illuminating the need for further evaluations of potential risk factors associated with ARI in this study sample.

1308

SENSITIVITY AND SPECIFICITY OF POINT-OF-CARE CIRCULATING CATHODIC ANTIGEN TEST BEFORE AND AFTER PRAZIQUANTEL TREATMENT IN DIAGNOSING *SCHISTOSOMA MANSONI* INFECTION IN ADULT POPULATION CO-INFECTED WITH HUMAN IMMUNODEFICIENCY VIRUS-1, NORTHWESTERN TANZANIA

Humphrey D. Mazigo[1], Stella Kepha[2], Safari Kinung'hi[3]

[1]Catholic University of Health and Allied Sciences, Mwanza, United Republic of Tanzania, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]National Institute for Medical Research, Mwanza, United Republic of Tanzania

The effect of HIV-1 on $CD4^+$ Th_2 cells is hypothesized to affect parasitological diagnosis of *Schistosoma mansoni* using Kato Katz technique. Thus, the use of more sensitive technique such as Point-of-Care Circulating Cathodic Antigen test is recommended. The present study assessed the sensitivity and specificity of the point-of-care Circulating Cathodic Antigen test in diagnosing *S. mansoni* infection before and after praziquantel treatment in adult population co-infected with HIV-1. A prospective longitudinal study was conducted among individuals aged 15-55 years at Igalagala village, north-western Tanzania. At baseline and four weeks after treatment, a single stool and urine samples were collected from each participants. Kato Katz (KK) technique and Point-of-Care Circulating Cathodic Antigen tests (POC-CCA) were used for diagnosis of *Schistosoma mansoni.* At baseline, based on KK and POC-CCA, the prevalence of *S. mansoni* was 57.8% (95%CI: 52.9 – 62.4) and 87.5% (95%CI: 83.9 – 90.4). The prevalence of HIV-1 infection was 6.9% (95%CI: 4.8 – 9.8). Based on KK technique and POC-CCA test, 3.6% and 5.7% of the study participants were co-infected with *S. mansoni* and HIV-1. Four weeks after treatment, based on KK technique and POC-CCA, the prevalence of *S. mansoni* was 17.6% and 28.7%. At baseline the sensitivity and specificity of POC-CCA were 96.3% (95%CI: 93.1-98.3) and 24.6% (95%CI: 18.4-31.6). In the HIV-1 seropositive group, the sensitivity and specificity of POC-CCA were 93.3% (95%CI: 68.1-99.8) and 28.6% (95%CI: 8.4 – 58.1). Four weeks after treatment, the sensitivity and specificity of POC-CCA were 47.8% (95%CI: 26.8 – 69.4) and 74.7% (95%CI: 67.9 – 80.8). In conclusion, the sensitivity of POC-CCA in diagnosing *S. mansoni* infection is high than KK technique in adult individuals likely to have low infection intensity and co-infected with HIV-1. However, its sensitivity decreases following praziquantel treatment but remained higher then Kato Katz technique. If the goal of the post-treatment is to identify uncured individuals, then POC-CCA test offers the best choice.

1309

REPEATED DOSES OF PRAZIQUANTEL IN SCHISTOSOMIASIS TREATMENT (REPST) - SINGLE VERSUS MULTIPLE PRAZIQUANTEL TREATMENTS IN SCHOOL-AGE CHILDREN IN CÔTE D'IVOIRE: A STUDY PROTOCOL FOR AN OPEN-LABEL, RANDOMIZED CONTROLLED TRIAL

Pytsje T. Hoekstra[1], Miriam Casacuberta Partal[1], Abena S. Amoah[1], Lisette van Lieshout[1], Paul L. Corstjens[1], Roula Tsonaka[1], Rufin K. Assaré[2], Kigbafori D. Silué[2], Aboulaye Meité[3], Meta Roestenberg[1], Stefanie Knopp[4], Jürg Utzinger[4], Jean T. Coulibaly[2], Govert J. van Dam[1]

[1]Leiden University Medical Center, Leiden, Netherlands, [2]Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Abidjan, Côte D'Ivoire, [3]Côte d'Ivoire Ministry of Health, National Program Against Filariasis, Schistosomiasis and Geohelminths, Abidjan, Côte D'Ivoire, [4]Department of Epidemiology and Public Health, Swiss Tropical and Public Health Institute, Basel, Switzerland

Large scale administration of the anthelminthic drug praziquantel (PZQ) to at-risk populations is the cornerstone of schistosomiasis control, although persisting high prevalence of infections in some areas and growing concerns of PZQ resistance have revealed the limitations of this strategy. Most studies assessing PZQ efficacy have used relatively insensitive parasitological diagnostics, such as the KatoKatz (KK) and urine-filtration (UF) methods, thereby overestimating cure rates (CRs). This study aims to determine the efficacy of repeated PZQ treatments against *Schistosoma mansoni* infection in school-age children in Côte d'Ivoire using the traditional KK thick smear technique, as well as more sensitive antigen- and DNA detection methods. To determine the efficacy of multiple PZQ treatments, an open-label, randomized controlled trial will be conducted in the region of Taabo in Côte d'Ivoire, an area endemic for *S. mansoni*. This 8-week trial includes four two-weekly standard doses of PZQ in the "intense treatment" intervention group and one standard dose of PZQ in the "standard treatment" control group. The efficacy of PZQ will be evaluated in stool samples using the KK technique and real-time PCR as well as in urine using the point-of-care circulating cathodic antigen (POC-CCA) test and the up-converting phosphor, lateral flow, circulating anodic antigen (UCP-LF CAA) assay. The primary outcome of the study will be the difference in CR of intense versus standard treatment with PZQ on individuals previously positive for *S. mansoni* measured by KK. Secondary outcomes include the difference in CR and intensity reduction rate (IRR) between the intense and standard treatment groups as measured by the other diagnostic tests, as well as the accuracy of the different diagnostic tests, and the safety of PZQ. This study will provide data on the efficacy of intense PZQ treatment on the clearance of S. mansoni, measured with several diagnostic techniques. These findings will inform future mass drug administration (MDA) policy and shed light on position of novel diagnostic tools to evaluate schistosomiasis control strategies.

Hospital NHS Foundation Trust, London, United Kingdom, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [5]Ministère de la Santé Publique, Antananarivo, Madagascar, [6]London School of Hygiene & Tropical Medicine, London, United Kingdom, [7]Royal United Bath NHS Foundation Trust, Bath, United Kingdom

We present a follow-up study investigating schistosomiasis-related, hepatic morbidity in children in Madagascar (Marolambo District) previously reported to have a high prevalence of *Schistosoma mansoni* infection. Circulating cathodic antigen (CCA) and Kato-Katz stool analysis were used to test 298 children (5-14 years old) for *S. mansoni*. Abdominal ultrasound (US) was performed and interpreted based on the Niamey Protocol. In CCA analysis, 97.7% of children (291/298) were infected with *S. mansoni*. Kato-Katz analysis revealed heavy infections in 18.1% (54/298) of the children. Preliminary US data show that an estimated 5 % of children have early signs of liver fibrosis. Persistent high prevalence of childhood intestinal schistosomiasis in this area of Madagascar appears associated with hepatic complications in a small, but clinically significant minority.

1311

BILHARZIOSIS IN MIGRATION MEDICINE - AN UNDERESTIMATED PROBLEM?

Sven Kalbitz[1], Frederike Neumann[1], Thomas Kuntz[1], Hanna Axelson[1], Anika Theunert[1], Lena Seelig[2], Heike Bisanz[3], Claudia Maßlau[3], Daniela Geister[3], Ingo Wallstabe[2], Volker Wiechmann[3], Thomas Grünewald[1]

[1]Klinikum Sankt Georg Klinik für Infektiologie/Tropenmedizin, Nephrologie und Rheumatologie, Leipzig, Deutschland, Leipzig, Germany, [2]Klinikum Sankt Georg Klinik für Gastroenterologie, Hepatologie, Diabetologie und Endokrinologie, Leipzig, Germany, Leipzig, Germany, [3]Klinikum Sankt Georg Institut für Pathologie und Tumordiagnostik, Leipzig, Deutschland, Leipzig, Germany

Bilharziosis is one of the most common infectious diseases in the world, with a prevalence of about 200 million people. Up to 200k people die annually, mainly as a result of late complications, such as Liver cirrhosis, hepatocellular or bladder carcinoma.The question of whether an intestinal invasive schistosomiasis with liver or pulmonary involvement is present, has significant consequences for the person concerned with regard to long-term health.Patients with confirmed intestinal schistosomiasis (proven by positive stool microscopy) were assigned and examined to explore hepatic and / or pulmonary manifestations. Lower intestinoscopy was done in every patient, addtionally, abdominal and cardiac ultrasound were performed. In case of suspect findings, liver biopsy was also done. The results from these tests were compiled to assess the extent of invasive infection. Of 23 patients treated, 22 (95.7%) were male and one female (4.3%). Schistosoma mansonii was detected in 22 patients and *Schistosoma haematobium* in one patient (excluded from further analysis). In all patients, schistosomalantibodies were detected in the blood, 20 patients (95.2%) had signs endoscopic of intestinal schistosomiasis, histological evidence was proven in 15 patients (71.4%). Sonographic abnormalities of the liver were seen in 15 patients (68.2%), with increased echogenic liver parenchyma (45.5%) or signs of pericholangiolar fibrosis (22.7%). Histologically, hepatic involvement was confirmed in 15 patients (83.3%). Elevated liver enzymes were detected in only one patient, cholestasis parameters in five (21.7%). Furthermore, 17 patients (90%) had marked increased immunoglobulin E was increased, more than half of the patients presented with blood eosinophilia (52.2%). All patients were successfully treated with praziquantel (stool microscopy negative four weeks after treatment).The high level of invasive infections in the cohort presented is striking. Obviously, strategies for the prevention and early detection of late complications have to be implemented in the care of patients with bilharziosis.

1312

OPTIMIZING STRATEGIES TO DIAGNOSE AND CONTROL INTESTINAL SCHISTOSOMIASIS IN A LOW AND MODERATE ENDEMICITY AREA OF BRAZIL

Anna E. Phillips

Imperial College, London, United Kingdom

Current diagnostic methods for intestinal schistosomiasis (detection of eggs in stool by the Kato-Katz (KK) method) are limited and may be particularly unreliable at low infection intensities, as would be expected after several rounds of treatment or in regions where transmission is low. In order to overcome some of the pitfalls of the KK method, new and more sensitive tests for the diagnosis of schistosomiasis have been developed. A point-of-care test for detecting schistosome circulating cathodic antigen (POC-CCA) has been documented to be a sensitive and specific alternative to KK through direct comparisons in several endemicity settings. However specific data comparing multiple KK over several days with antigen detection tests in low prevalence settings is currently lacking. The primary aim of this project is to compare the performance of POC-CCA with that of the three days of duplicate KK in addition to PCR, in an area with moderate *Schisosoma mansoni* infection in Sergipe State and low endemicity area of Minas Gerais State, in Brazil. The present study aims to enhance knowledge of the spatial distribution of schistosomiasis in these two states of Brazil, and generate data for a better planning of interventions and strategies within the National Brazilian Schistosomiasis Control Program (PCE), especially in areas with low endemicity and/or low parasite loads.

1313

PERFORMANCE OF POC-CCA AND KATO-KATZ TO DIAGNOSE *SCHISTOSOMIASIS MANSONI* IN LOW AND MODERATE ENDEMICITY AREAS OF BRAZIL

Agostinho Gonçalves Viana[1], Pedro Henrique Gazzinelli-Guimarães[2], Vanessa Normandio Castro[1], Lilian Lacerda Bueno[1], Stefan Michael Geiger[1], Silvio Santana Dolabella[3], Anna Phillips[4], Ricardo Toshio Fujiwara[1]

[1]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [2]National Institutes of Health, Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [3]Universidade Federal de Sergipe, Aracaju, Brazil, [4]Imperial College London, Department of Infectious Disease Epidemiology, London, United Kingdom

Current diagnostic methods for intestinal schistosomiasis (detection of eggs in stool by Kato-Katz (KK)) are limited and may be particularly unreliable at low levels of infection, as would be expected after several rounds of treatment or in regions where transmission is low. In order to overcome some of the pitfalls of the KK method, there has been interest in developing more sensitive tests for the diagnosis of schistosomiasis. The Point-Of-Care (POC) Circulating Cathodic Antigen (CCA) urine assay (POC-CCA) has been documented to be a sensitive and specific alternative to KK in several moderate and high endemicity settings. Specific data comparing the performance of microscopy and antigen detection tests in low Schistosomiasis prevalence settings, however, is currently lacking. In this context, the aim of this work was to compare the performance of POC-CCA and KK in the urine and stool samples of school-aged children (SAC) (5-16 years-old) from low endemic area of Minas Gerais State, and in a moderate endemic area of Sergipe State Brazil. For the KK assay, three stool samples were collected, and 2 KK slides were prepared per sample. Up to the present moment, of the 1,223 SAC surveyed in the state of Minas Gerais, 31 (2.5%) of the samples were positive for KK (intensity mean, 20 eggs mg/stool). However, when evaluated the results of the POC-CCA test, 222 (18.5%) samples were positive in Minas Gerais state. Moreover, of the 542 SAC surveyed until the moment in Sergipe state, 188 (35%) samples were positive by the POC-CCA test, considering trace as

positive. The frequency of POC-CCA positives in both areas, considering trace as negative were 96 (7,9%) and 114 (26,5%) respectively. KK results from Sergipe state are still being analysed. Taken together our results from Minas Gerais state indicate that POC-CCA is a more sensitive test than Kato-Katz in areas of low endemicity, even considering trace results as negative. Urine, stools and sera from all the individuals will be tested for other based tests (qPCR and UCP-CAA) for the calculation of sensitivity, specificity, and ultimately, to define the relationship between POC-CCA and KK at low endemicity areas.

1314

FIRST MAPPING OF HUMAN SCHISTOSOMIASIS IN BENIN: EVIDENCE OF COUNTRYWIDE *SCHISTOSOMA HAEMATOBIUM* PREDOMINANCE

Moudachirou Ibikounlé[1], Ablavi Onzo-Aboki[1], Jean Jacques Tougoue[2], Boris Savassi[1], Pelagie M. Boko[3], Joel E. Siko[1], Aboudou Dare[2], Wilfrid Batcho[3], Achille Massougbodji[1], Dorothee A. Kinde-Gazard[1]

[1]University of Abomey-Calavi, Cotonou, Benin, [2]RTI International, Washington, DC, United States, [3]National NTD Program, Cotonou, Benin

National mapping of schistosomiasis infections was conducted for the first time in national scale from 2013 to 2015. This mapping aimed to provide basic epidemiological data essential for the implementation of the national strategy against the neglected tropical diseases in the context of achieving the WHO target of controlling these infections by 2020. Parasitological surveys were conducted from 2013 to 2015 in three hundred eighty-five selected sampling units for baseline mapping in all districts (seventy-seven districts): Fifty school children (25 females and 25males) aged 8-14 years were randomly selected per site. A total of 19,000 samples (urine and stool) were examined using haematuria dipsticks, parasite-egg filtration for urine samples and the Kato-Katz technique for stool specimens. Two species of human schistomiasis were observed with intra- and inter-specific variations in the prevalence and the intensity of these parasites. Urinary schistosomiasis was widely distributed and present in 75/77 districts with an average prevalence of 17.56% (95° CI:17.02%-18.10%) at the national level compared to *Schistosoma mansoni* focused and found in 28/77 districts with 2.45% (95° CI:2.23%-2.67%) as national prevalence. The cumulative prevalence was 19.78% (95% CI:19.21%-20.34%) and 45/77 of the districts required a preventive chemotherapy treatment according to World Health Organization recommendations for schistosomiasis control. In several districts where the two species are endemic with prevalence more than 10%, *S. haematobium* were most prevalent parasites. Boys are significantly more infected than girls (18.29% v 16.82%, p=0.007). Most infestations were light except in the districts located in the department of Atacora where children were highly infected for *S. haematobium* (more than 50 eggs/10mL). In all districts surveyed, children are suffering more for diseases related to the lack of sanitation and hygiene than water related disease. This mapping study provided a global view of the epidemiological pattern of schistosomiasis, and was essential for the implementation of a control strategy and the establishment of sentinel sites.

1315

LOWER CURE RATE AND EGG REDUCTION RATES FOR *SCHISTOSOMA JAPONICUM* USING PRAZIQUANTEL AT 40 MG/KG DOSE

Stephanie S. Maldonado[1], Blanca Jarilla[2], Sangshin Park[1], Haiwei Wu[1], Jonathan D. Kurtis[1], Jennifer F. Friedman[1], Mario Jlz[2]

[1]Brown University, Providence, RI, United States, [2]Research Institute of Tropical Medicine, Manilla, Philippines

Historically, Praziquantel dosing for *Schistosoma japonicum* (60 mg/kg) had been higher than doses recommended for *S. mansoni* and *S. haematobium* (both 40 mg kg). The higher dosing for *S. japonicum* was based on early efficacy and cure rates in studies conducted among Filipino adults. Recently, the World Health Organization changed their dosing recommendations to 40 mg/kg in response to a meta-analysis of studies examining cure rates (CR) and egg reduction rates (ERR) at both doses. Of note, only 4 of 55 studies used in the meta-analysis were conducted in *S. japonicum*endemic areas. In recent studies, we noted higher treatment failure rates at the lower dose than we had with 60 mg/kg dosing. The objectives of this study were to assess CR and ERR using 40 mg/kg of Praziquanel for *S. japonicum*, and compare these to a) WHO recommended targets and b) CR and ERR found in the same study area using 60 mg/kg in 2002. In this study, 301*S. japonicum* infected subjects ages 8-30 were enrolled and treated with 40 mg/kg Praziquantel. A Kato-Katz examination of stool (three stools each in duplicate) were conducted 4-5 weeks later. Overall CR at 40 mg/kg was 79.6% and the ERR was 87.6% (95%CI: 80.7, 94.5). Individuals with moderate or high intensity infection (N=33) had lower cure rates at 72.7% as compared to those with light intensity infection at 80.6%. ERR among those with moderate or high intensity infections were 99.1% (95%CI: 98.5-99.8) and 86% (95%CI: 78.2-93.9) among those with low intensity infections. There were no significant differences in ERR or CR by gender or age. In 2002, CR and ERR utilizing 60 mg/kg were 93.2% and 92.2 (95%CI 86.1-98.3) respectively, using similar methodology. The ERR found in recent studies using 40 mg/kg falls below the WHO recommended target of 90% and is lower than that found using 60 mg/kg dosing in the same study area, raising the concern that 40 mg/kg may be insufficient for the treatment of *S. japonicum.*

1316

EVALUATION OF SENSITIVITY AND SPECIFICITY OF CIRCULATING CATHODIC ANTIGEN IN THE CONTEXT OF *SCHISTOSOMA JAPONICUM* AT USING LATENT CLASS ANALYSIS

Sangshin Park[1], Haiwei W. Wu[1], Stephanie Maldonado[1], Blanca Jarilla[2], Jonathan D. Kurtis[1], Jennifer F. Friedman[1], Mario Jiz[2]

[1]Brown University, Providence, RI, United States, [2]Department of Health, Research Institute for Tropical Medicine, Manila, Philippines

The Kato Katz (KK) method of evaluating stool samples to quantify eggs remains the diagnostic approach for diagnosing *Schistosoma japonicum*. This method is costly, labor intensive, and demonstrates low sensitivity, particularly if fewer than three separate stools are evaluated. A point-of-care circulating cathodic antigen (CCA) test of urine has been shown to be more sensitive than KK in the context of *S. mansoni* and *S. haematobium*. Less is known about the test characteristics of CCA for *S. japonicum*. The use of latent class analysis (LCA) approaches has aided the evaluation of CCA, as this analytic tool is better able to evaluate sensitivity and specificity in the absence of a gold standard. In *S. japonicum* endemic villages in Leyte, The Philippines, 741 subjects were screened for the presence of *S. japonicum* by evaluating three separate stools, each in duplicate, by KK. Within one week of KK assessments, a CCA test was performed on a single urine sample. Of these 741, 291 subjects who were found to have *S. japonicum* were enrolled into a longitudinal study and treated with 40 mg/kg of Praziquantel, and both KK and CCA assessments were repeated 4 weeks after treatment. Prior to treatment, we found the prevalence of infection as assessed by KK was 30.6%. The prevalence as assessed by CCA was 77.3%. Using Bayesian LCA, the sensitivity and specificity of CCA were 94.5% [90.0-99.5] and 84.1% [42.1-98.5] and the sensitivity and specificity of three KK were 32.3% [27.9-36.4] and 76.4% [67.8-83.9]. Four weeks after treatment, by LCA, the sensitivity and specificity of CCA were 88.0% [79.1 - 98.9] and 71.0 [31.4 - 97.1], respectively and the sensitivity and specificity of three KK were 25.2 [19.2 - 36.8] and 88.8 [76.5 - 97.5] respectively. Overall, CCA was much more sensitive that KK in the diagnosis of *S. japonicum*. This point of care test may be used in conjunction with mass drug administration to reduce patient refusal related to lack of knowledge of infection status, in community surveys to more rapidly assess prevalence, and in areas approaching elimination where more sensitive tests are able to detect low intensity infections.

1317

COMPARISON OF THE EFFICACY OF TWO ANTIPARASITIC TREATMENT FOR SHEEP INFECTION WITH *FASCIOLA HEPATICA*

Raul Enriquez[1], Percy Soto[2], Karina Bardales[3], Cesar Sedano[3], Luis Gomez[4], Saul Santivañez[3], Armando Gonzalez[4]

[1]Universidad Peruana Cayetano Heredia, Puente Piedra, Peru, [2]Asociación para el Desarrollo de la Investigación Estudiantil en Ciencias de la Salud (ADIECS), Universidad Nacional Mayor de San Marcos, Lima, Peru, [3]Universidad Peruana Cayetano Heredia, Lima, Peru, [4]Universidad Nacional Mayor de San Marcos, Lima, Peru

Fasciolosis, a parasitic infection caused by *Fasciola hepatica*, mainly affects ruminants in endemic areas causing economic losses among affected population. Triclabendazole (TBZ) has been used as the first line treatment for controlling the disease; however, due to the increasing resistance, other antiparasites such as closantel (CST) has been used as an alternative. Efficacy of CST against adult stage has been assessed, but its efficacy against young stages is still be discussing. The current study aims to estimate the long-term efficacy of CST against TBZ. We randomly assigned 79 naturally infected sheep from endemic areas into two groups: 41 for of TBZ 10 mg/kg (Zolinex Dorado®, Biomont Lab) and 38 for CST 10 mg/kg (Prosantel®, Montana Lab), both administrated as a unique dose. The primary outcome was the cure rate at week 14th. , defined as the complete absence of eggs in stools samples and young/adults stages in the liver of necropsied sheep. Coproparasitological assessment was performed using the sedimentation technique. Egg count per gram of feces was calculated using the McMaster method. Detection of young/adults trematodes in liver was obtained by in situ observation during necropsy. Cure rate at week 14th in CST group (89.5%) was significantly higher than TBZ group (31.7%) (IRR = 2.8; CI 95% 1.7 to 4.5; $p < 0.001$). Mean (SD) number of trematodes in TBZ group was 31.6 (23.5) in comparison with CST group which has no one trematode in all sheep. Furthermore, despite that CST group has zero epg at week 4th, there were some eggs at week 8th that increased for the week 14th. Closantel and Triclabendazol showed a clear adulticidal action effect; however, the appearing of eggs after 8 weeks should be an indicator of poor effect among young stage.

1318

DIFFERENTIAL IMPACT OF MASS AND TARGETED DEWORMING CAMPAIGNS FOR SCHISTOSOMIASIS CONTROL IN CHILDREN: A SYSTEMATIC REVIEW AND META-ANALYSIS

Danielle Cribb[1], Naomi E. Clarke[1], Suhail A. Doi[2], **Susana Vaz Nery**[3]

[1]Australian National University, Canberra, Australia, [2]Qatar University, Sydney, Qatar, [3]University of New South Wales, Sydney, Australia

Chronic infections with *Schistosoma* species lead to significant morbidity among the world's poorest populations, including anaemia, malnutrition, and poor physical and cognitive development. Less frequently they can cause fatal complications. Regular delivery of praziquantel to school-aged children (SAC) is the principal strategy for schistosomiasis control. Recent studies suggest that if chemotherapy programs are delivered using a community-based approach they will achieve a higher coverage of SAC. Moreover, if they are expanded to treat entire communities, they may have an additional impact on transmission and eventually lead to elimination. This systematic review and meta-analysis aimed to compare the impact of community-wide and child-targeted administration of praziquantel on schistosomiasis prevalence in school-aged children. Studies reporting prevalence before and after child-targeted or community-wide treatment were identified searching MEDLINE, EMBASE, and Web of Science. Data extracted included *Schistosoma* species, drug administration strategy, drug dose, number of rounds of chemotherapy, treatment coverage, diagnostic method, follow-up interval, and schistosomiasis prevalence before and after treatment. Inverse variance weighted generalised linear models were used to examine the impact of community-wide vs child-targeted chemotherapy on prevalence reduction in school-aged children. We will present results of the generalised linear models, used to test the hypothesis that similar to a recently published meta-analysis comparing community-wide versus child-targeted deworming for control of soil-transmitted helminths, children will show a significantly greater prevalence reduction when praziquantel is administered to entire communities, compared to when it is administered to children only. The results of this meta-analysis may provide additional evidence to optimize current guidelines by expanding chemotherapy for schistosomiasis from child-targeted to community-wide treatment.

1319

DETECTING AND DISRUPTING ENVIRONMENTAL CONTAMINATION OF *SCHISTOSOMA MANSONI*

Teteh S. Champion[1], Stephanie Connelly[1], Cindy Connelly[1], Candia Rowel[2], Fred Besigye[2], Poppy H. Lamberton[1]

[1]University of Glasgow, Glasgow, United Kingdom, [2]Vector Control Division, Ministry of Health Uganda, Kampala, Uganda

For the estimated 240 million people across the tropics and sub-tropics infected with schistosomiasis, preventative chemotherapy with praziquantel is the primary control measure. Despite repeated mass drug administration with this tremocidal drug, schistosomiasis persists in highly endemic communities. Supplementary control measures to improve sanitation and/or access to cercariae-free water, could interrupt the free-living lifecycle stages and reduce this parasitic fluke's transmission. Our overall aim is to assess the potential for local, targeted engineering interventions to reduce environmental contamination by *Schistosoma mansoni.* To this end, our first objective was to develop a molecular assay to detect and quantify *S. mansoni* DNA in soil. Existing quantitative polymerase chain reaction (qPCR) assays were adapted to detect and quantify *S. mansoni* DNA from soil samples. To standardise the qPCR technique and determine the sensitivity of environmental DNA (eDNA) detection, *S. mansoni* egg-spiked soil samples of varying density were used. Thus, the lower limits of eDNA detection were ascertained enabling design of a field-based survey of environmental contamination. The field applicability of the qPCR assays were assessed in a high *S. mansoni* endemic area, proximal to Lake Victoria in Mayuge District, Uganda using environmental soil samples taken at increasing distances from open defecation and pit latrine sites. I will present the methods and preliminary results of this eDNA assay and their implications for local sanitation solutions and *S. mansoni* transmission.

1320

UNRAVELLING INTERACTIONS BETWEEN SCHISTOSOMES, THE MICROBIOME AND ANTI-HELMINTHIC DRUGS

Lauren V. Carruthers[1], Candia Rowel[2], Diana Ajambo[2], Fred Besigye[2], Andrina Nankasi[2], Moses Arinaitwe[2], Aidah Wamboko[2], Aaron Atuhaire[2], Edridah M. Tukahebwa[2], Christina L. Faust[1], Poppy H. Lamberton[1]

[1]University of Glasgow, Glasgow, United Kingdom, [2]Vector Control Division, Uganda Ministry of Health, Kampala, Uganda

Schistosomiasis is a neglected tropical disease that infects millions of people globally mainly in developing countries. In Mayuge District, Uganda, *Schistosoma mansoni* infection remains prevalent and has been increasing in some communities despite over a decade of annual mass drug administration interventions. The influence the microbiome may have on health and disease has become increasingly apparent in recent years, with correlations being observed between gut bacterial composition and intestinal helminth infection status both in natural and laboratory environments. This research aims to quantify associations between *S. mansoni* infection intensity, gut microbiome community structure and efficacy of anti-helminthic drug treatment: hypothesizing that gut microbiome diversity will reflect schistosome infection intensity

and affect treatment efficacy. Initially, stool samples were collected from three individuals and stored raw, in RNAlater, and in ethanol to compare how the preservation method in a remote field setting may influence the 16S rRNA microbiome sequencing profiles obtained. These samples were then frozen at the time of collection (0 h) and at doubling incremental time points from 1 – 32 h to explore the impact of time taken to freeze on microbial diversity and abundance. A cohort of 200 school-aged children were then enrolled in a longitudinal study. Children provided stool samples for microbiome analysis pre-treatment and at 24 h, 3 wk and 6 mth post-treatment with praziquantel and albendazole. At each time interval children were also tested for schistosomiasis and soil-transmitted helminthiasis, and 24 h dietary recall surveys were undertaken to control for dietary variation. Initial pilot study data optimizing storage and analysis for microbiome will be presented. Preliminary findings from the longitudinal study, controlling for individual demography and co-infections, will then be discussed. This study has important implications for understanding individual health outcomes and informing how individual variation could influence onward transmission in a community highly endemic for *S. mansoni*.

1321

ECO-EPIDEMIOLOGICAL SURVEY OF URINARY SCHISTOSOMIASIS IN TOGO'S OGOU DISTRICT

Olivia C. Kern[1], Mathias K. Adjabli[2], Morou Ibarin[3]

[1]Wellesley College, Wellesley, MA, United States, [2]Central Veterinary Laboratory, Lomé, Togo, [3]Togolese Ministry of Health, Lomé, Togo

Schistosoma blood flukes are found on three continents, yet roughly 85% of the estimated 700 million people at risk of infection live in Africa. While preventative chemotherapy (PC) control strategies have proven largely successful, in 2016, two of Togo's 40 health districts experienced a significant rise in urinary schistosomiasis cases despite six years of mass administered PC. To ascertain the cause of this anomaly, several aspects were examined, notably: PC drug delivery, public health awareness, and prevalence of parasite-infected snails in freshwater sources. We classified 3,280 field-collected snails between April and November 2017, and conducted qPCR diagnostics on those belonging to the *Bulinus* genus, a known intermediate host of schistosomiasis. We will present the latest data resulting from public health surveys, drug distribution evaluations, and snail infection load. These indicators will offer programmatic insights to aid the Togolese Ministry of Health's efforts to address infection control through the continuation of PC programs and the targeted use of molluscicides in affected waterways.

1322

PERSISTENCE OF SCHISTOSOMIASIS AND SOIL-TRANSMITTED HELMINTHS IN MALI DESPITE HIGH COVERAGE RATES: EXCLUDING LOW COVERAGE RATES AND COMMUNITY HEALTH WORKERS MOTIVATION AS CAUSE

Adama Y. Berthe[1], Yaya I. Coulibaly[1], Moussa B. Sangaré[1], Housseiny Dolo[1], Ilo Dicko[1], Salif S. Doumbia[1], Michel E. Coulibaly[1], Lamine Soumaoro[1], Siaka Y. Coulibaly[1], Atsou K. Midodji[1], Amy D. Klion[2], Ogobara Doumbo[1], Thomas B. Nutman[2]

[1]International Center for Excellence in Research-Mali (ICER-Mali), Bamako, Mali, [2]Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

In Mali, schistosomiasis and soil-transmitted helminth (STH) control activities have been in place since several decades. Despite these efforts, not only has schistosomiasis and STH persisted in the Bankass Health District (BHD), but there also was reported a very low coverage rate in 2016 of 64.8%. This study was initiated to assess the 2017 MDA coverage in Bankass Health District and the factors underlying the low coverage. A cross-sectional study was conducted in 19 health areas in BHD. We surveyed school age children (5-14 years) to determine the MDA coverage. A random cluster sampling was adopted to select households where questionnaires were administered to all volunteers aged from 5 to 14. The questionnaire was designed to assess the level of motivation of community health workers. We surveyed 2128 school age children and 52 health workers that participated in the 2017 MDA campaign. The epidemiological coverage rate for praziquantel was 93.51% (1990/2128); 95% CI [92.38% - 94.52%] and for albendazole 95.25% (2027/2128); 95% CI [94.26% -96.12%]. Adverse events (AEs) were reported in 399 respondents. Of the 399 AEs, 76.94% (307/399) were classified as minor whereas 23.06% (92/399) were considered moderate. No serious AEs were reported. Among the 98 (4.6%) children who did not receive medications as part of the MDA activities, the main reasons stated included a lack of awareness of the MDA in 31.63% (31/98) and an inability to access the centers where the drug distribution was taking place (26/98). Most of the health workers surveyed stated that they were motivated to participate in MDA campaigns in the future, and they suggested that increased incentives during the MDA campaigns would make them even more successful. The extraordinarily high coverage rate during this campaign in 2017 suggests that the low coverage rates reported in the prior MDA campaign may have been due to under reporting. In conclusion, the current data suggest that the reported low MDA coverage in BHD was likely due to underreporting, though this does not explain the persistence of schistosomiasis and STH in this health district.

1323

FACTORS ASSOCIATED WITH URINARY SCHISTOSOMIASIS AMONG IRRIGATION FARMERS IN MARKE COMMUNITY, JIGAWA STATE, NIGERIA

Usaini Bala[1], Kabir Getso[2], Sulaiman Idris[3], Muhammad Sambo[3], Saheed Gidado[1], Umar Ayuba[3], Patrick Nguku[1], Nuruddeen Aliyu[1], Gabriella Poggensee[4]

[1]African Field Epidemiology Network, Abuja, Nigeria, [2]Kano State Ministry of Health, Kano, Nigeria, [3]Ahmadu Bello University, Zaria, Nigeria, [4]Nigeria Field Epidemiology and Laboratory Training Program, Abuja, Nigeria

Urinary schistosomiasis is water borne parasitic infection. Globally, over 200 million people are infected and 20 million have severe disease. Nigeria had about 29 million cases of schistosomiasis in 2008. We conducted this study to determine the prevalence, intensity and factors associated with urinary schistosomiasis among irrigation farmers in Marke community of Jigawa state. A cross-sectional survey was conducted, 430 irrigation farmers aged 15 years and above from Marke community were recruited using systematic random sampling technique. Urine samples were collected from the participants and examined for ova of *Schistosoma haematobium* using filtration technique. Data on socio-demographic variables and exposure for schistosomiasis were collected using semi-structured questionnaire. We calculated adjusted odds ratios using logistic regression method to assess risk factors. Of the 430 respondents 429(99.8%) were male. Median age (range) was 37(15-80) years. A total of 171 (39.8%) respondents were infected with urinary schistosomiasis. Median egg count (range) was 8(2-298) eggs/10ml of urine and 159 (93%) of the infected respondents had low intensity of infection (excreting less than 50 eggs/10ml of urine). Age less than 25 years (AOR 4.05; 95% CI: 1.4-8.3), being single (AOR 3.2; 95% CI: 1.8-5.5) and frequent washing of clothes (≥2 times per week) in open water bodies (AOR 1.8; 95% CI: 1.2-2.7) were found to be independent risk factors for urinary schistosomiasis among irrigation farmers in Marke community. The prevalence of urinary schistosomiasis among irrigation farmers in Marke community was moderate while the intensity of infection was found to be low. Age less than 25 year and frequent washing of clothes (≥2 times per week) in open water bodies are independent risk factors for the disease. We gave health education on the risk of transmission of the disease to the entire community and recommended mass drug administration to the high risk group.

1324

GEOGRAPHIC SPREAD OF AN AVIAN EYEFLUKE WITH ZOONOTIC POTENTIAL

Kayleigh Chalkowski

Auburn University, Auburn, AL, United States

Philophthalmus are ocular parasites utilizing snail intermediate and avian definitive hosts in a complex life cycle. Since the last review on the genus published in 1995 by Nollen and Kanev, at least 60 articles have improved our understanding of these parasites. Furthermore, while *Philophthalmus* has long been known to be globally widespread, *P. gralli* in particular appears to be a relatively new introduction to the Americas, where human modification of aquatic habitat may encourage proliferation and spread of invasive *P. gralli*. Given that this parasite has zoonotic potential, the continued spread of this parasite presents a threat to public health.

1325

NUTRITION AND *FASCIOLA HEPATICA* INFECTION AMONG CHILDREN IN THE ANTA PROVINCE OF CUSCO, PERU

Camille Webb[1], Maria L. Morales[2], Martha Lopez[2], Miguel M. Cabada[1]

[1]University of Texas Medical Branch, Galveston, TX, United States, [2]Universidad Peruana Cayetano Heredia-University of Texas Medical Branch Collaborative Research Center, Cusco, Peru

Fasciola hepatica infection disproportionately affects children from the highlands of Bolivia and Peru, where prevalence can reach 70%. Acute infection is often asymptomatic, however chronic infection can remain undiagnosed for years and has been associated with anemia and undernutrition. We conducted a cross-sectional study to evaluate the impact of fascioliasis among all children attending pre-school and school in 26 communities in the Anta province in the Cusco region of Peru. We conducted interviews at school and home to collect information on demographics, socioeconomics, medical history and nutrition. Blood samples were tested for complete cell count, FAS2 ELISA antibodies and transaminases Three stool samples were collected per patient and tested with Kato-Katz and Lumbreras rapid sedimentation for parasites. Children's height and weight were recorded and used to calculate body mass index and Z scores for weight and height for age. 2958 children were included in the analysis. 50% were male, and mean age was 9.7 years (±3.59). 111 (3.9%) reported prior treatment for malnutrition, and 389 (13.7%) for parasite infection. 262 (8.9%) had at least one positive test for *Fasciola* infection. The median HAZ was -1.41 (IQR: -2.03 to -0.82) and was similar in males and females. 768 (26.1%) met WHO criteria for stunting with HAZ < -2. Children with any positive *Fasciola* test had a lower median HAZ compared to children with negative *Fasciola* tests (-1.51 vs -1.40, p=0.023). Median BMI was higher in those with a positive *Fasciola* test as compared to those without a positive test (17 vs 17.5, p=0.002), though there were no differences in BMI for age z score (BAZ) (0.24 vs. 0.30). History of treatment for malnutrition was associated with lower HAZ in those who did not test positive for *Fasciola*, but not in those with a positive test for *Fasciola*. Among those with *Fasciola* eggs in stool, BMI and weight for age were similar in the group with a high egg burden (>100 eggs) as compared to those with a low egg burden. A positive serologic test for *Fasciola* was not associated with low HAZ or WAZ.

1326

ECOLOGY OF *SCHISTOSOMA MANSONI* TRANSMISSION: LEVERAGING SEASONAL VARIABILITY FOR CONTROL

Larissa Anderson, Helen Wearing

University of New Mexico, Albuquerque, NM, United States

Schistosomiasis, caused by various trematodes of the genus *Schistosoma* is one of the five most prevalent parasitic infections worldwide. The transmission cycle of *Schistosoma mansoni* involves both humans and snails from the genus *Biomphalaria* as obligatory hosts. *S. mansoni* is endemic across much of sub-Saharan Africa and, as such, has been the subject of control measures including mass drug administration campaigns targeting the parasite in the human host and molluscicides targeting the snail population. Fluctuations in the aquatic environment and in snail population size or community composition may concentrate or dilute the free-living portions of the schistosome life cycle. Variation in these populations can impact the infection pressure experienced by both hosts and therefore presents an opportunity to potentially magnify the effect of control measures through seasonal treatment timing. To quantify seasonal variation in snail abundance, we collected absolute and relative snail density, snail community composition, and *S. mansoni* infection prevalence bimonthly from a perennial stream in the Kisumu, Kenya area from July 2015 - January 2018. Daily rainfall and temperature data was also obtained for January 2013 -January 2018. We used time-series analysis, to identify the conditions most predictive of host snail density and infection prevalence. There were substantial seasonal fluctuations in the infection prevalence. These fluctuations do not appear to be directly related to shifts in temperature and rainfall but instead to prior snail community composition, with a correlation between high *S. mansoni* prevalence and prior dominance of Biomphalaria in the snail assemblage. These data were then used to parameterize seasonal forcing of snail population size and infection prevalence in a dynamic model of schistosomiasis. This model allows us to identify the times of year when either mass drug administration or molluscicides alone, or a combination of these control strategies, results in the maximum reduction in the force of infection experienced by the human population.

1327

FIELD AND MODELING STUDIES OF THE INFLUENCES OF SNAIL AND TREMATODE BIODIVERSITY ON *SCHISTOSOMA MANSONI* TRANSMISSION IN AND AROUND LAKE VICTORIA

Martina R. Laidemitt[1], Larissa C. Anderson[1], Helen J. Wearing[1], Martin W. Mutuku[2], Gerald M. Mkoji[2], Eric S. Loker[1]

[1]University of New Mexico, Albuquerque, NM, United States, [2]Centre for Biotechnology Research and Development, Kenya Medical Research Institute (KEMRI), Nairobi, Kenya

Human infectious agents exist within a complex environmental milieu that influences the likelihood of transmission, and nowhere is this more evident than with parasites with multi-host life cycles. Among them is *Schistosoma mansoni*, which is transmitted primarily by three different species of *Biomphalaria* in western Kenya. We show that the force of infection of *S. mansoni* to people as estimated by the number cercariae-producing snail infections is significantly influenced by domestic cattle and wild vertebrate hosts because of their role in transmitting digenetic trematodes with larval stages that compete with and/or displace *S. mansoni* sporocysts in snails. Modeling efforts indicate the removal of one key trematode parasite, an amphistome species infecting cattle, would increase the number of *B. pfeifferi* shedding *S. mansoni* cercariae by 3-fold. Furthermore, the permanence of aquatic habitats influences the species composition of *Biomphalaria* and of other snails, again with indirect effects on trematode abundance and the likelihood that cercariae-producing infections of *S. mansoni* develop. Our results suggest that the predictable co-dominant exploitation of aquatic habitats by domestic animals and humans have enabled some trematodes to depend on and exploit *S. mansoni* for their transmission. Our results help expand a conceptual framework to better understand the many factors dictating the abundance of this and other endemic neglected tropical diseases.

1328

AN ECO-EVOLUTIONARY PERSPECTIVE ON SCHISTOSOMIASIS

Julia C. Buck[1], Giulio A. De Leo[2], Benyamin Rosental[2], Susanne H. Sokolow[2]

[1]UC Santa Barbara, Santa Barbara, CA, United States, [2]Stanford University, Palo Alto, CA, United States

In areas where human schistosomiasis is endemic, infection prevalence, worm burden, and egg output are known to rise rapidly through childhood, reach a peak at 8-15 years of age, and decline thereafter. A similar peak ("overshoot") followed by return to equilibrium infection levels often occurs after mass drug administration. These patterns are assumed to be due to acquired immunity, which is induced by exposure, directed by the host's immune system, and develops slowly over the lifetime of the host. Here we offer four alternative explanations for these patterns and present evidence supporting or refuting each one: 1) differential exposure of hosts, 2) differential mortality of hosts, 3) progressive pathology, and 4) concomitant immunity and worm senescence. These alternative explanations are not mutually exclusive and do not rule out an immune response by the host. Additionally, the final explanation approaches schistosomiasis from an eco-evolutionary perspective, suggesting that acquired immunity is orchestrated by adult worms for their own benefit. We present a mathematical model showing that concomitant immunity, in combination with senescence of adult worms, can explain the age-intensity pattern observed in endemic areas, and we propose experiments to test this hypothesis. Our results have implications for the treatment of human schistosomiasis. Specifically, if acquired immunity is worm-directed, then treatment of long-standing infections should be avoided, as old worms with low fitness could protect hosts against new infections. Furthermore, our results could suggest promising new directions in the effort to control human schistosomiasis, as sterile adult worms, single-sexinfections, or a vaccine that mimics the immune-modulating activity of adult worms might protect the host from new infections, while minimizing pathological consequences. We emphasize the value of an eco-evolutionary perspective on host-parasite dynamics.

1329

COMPUTER VISION AND MACHINE LEARNING ENABLE ENVIRONMENTAL DIAGNOSTICS FOR TARGETING SCHISTOSOMIASIS CONTROL

Susanne Sokolow[1], Zac Yung-Chun Liu[1], Andy Chamberlin[1], Chris Le Boa[1], Chelsea L. Wood[2], Isabel J. Jones[1], Richard Grewelle[1], Giulio A. De Leo[1]

[1]Stanford University, Pacific Grove, CA, United States, [2]University of Washington, Seattle, WA, United States

A capacity gap in the developing world hinders broad scale environmental monitoring of schistosomiasis risk. A major component of this gap is a shortage of people with expertise in snail and trematode identification in Africa and elsewhere in the developing world where schistosomiasis is endemic. Yet, with the rapid advance of new affordable computing technology, promising schistosome 'environmental diagnostics' based on computer vision and machine learning technologies might emerge to fill this capacity gap and help to successfully target control measures to high-risk environments. Focusing on a case study in northern Senegal, we demonstrate a proof of concept that computer vision can assist in snail and trematode cercarial identification, with accuracy rivaling that of well-trained human technicians. We outline steps for scaling this technology, enabling citizen science, and expanding the availability and access to environmental monitoring data for schistosomiasis control efforts. We conclude that computer vision and machine learning technologies can modernize environmental diagnostics for trematode parasites and their snail hosts, with promising implications for the World Health Assembly's stated goal to eliminate schistosomiasis.

1330

TOXICS (PB, CD) AND TRACE ELEMENTS (ZN, CU, MN) IN WOMEN DURING PREGNANCY AND AT DELIVERY, SOUTH BENIN, 2014-2015

Marine Guy[1], Manfred Accrombessi[2], Nadine Fievet[2], Emmanuel Yovo[2], Achille Massougbodji[3], Barbara Le Bot[4], Philippe Glorennec[4], **Florence Bodeau-Livinec**[5], Valérie Briand[6]

[1]IRD UMR216, Paris, France, [2]IRD UMR216, Cotonou, Benin, [3]IRCB, Cotonou, Benin, [4]EHESP, Rennes, France, [5]EHESP, Paris, France, [6]INSERM U1219, Bordeaux, France

Fetal development can be hindered in case of abnormal maternal concentrations of toxic and trace elements. Few data are available in African countries. Our aim was to assess the body burden of lead (Pb), cadmium (Cd), manganese (Mn), zinc (Zn) and copper (Cu) in pregnant women in Benin. The study was carried out in Sô-Ava district, from November 2015 to April 2016. Sixty women were recruited from the RECIPAL pre-conceptional cohort study. In all women, blood samples were collected during the first trimester of pregnancy. Thirty-two women had additional maternal and cord blood samples collected at delivery. Blood samples were analyzed by inductively coupled plasma mass spectrometry. At delivery, Cd median (range) concentration in maternal blood was 0.34µg/L (0.18-1.63µg/L) in this non-smoking population. Pb median (range) concentration in maternal blood at delivery was 37.4 µg/L (6.3-110.6µg/L), with 31.3% of blood Pb levels above the recommended 50µg/L threshold. These pregnant women lived in lakeside villages, thus not in an urban area. Potential sources of Pb exposure during pregnancy identified were having water supply by drill pump and activities such as smoking fish by the woman and fishing by the household head. Pb, Cd, Mn and Cu blood concentrations were significantly higher at delivery than during the first trimester of pregnancy. Pb, Cd, Zn and Cu concentrations were significantly lower in cord blood than in maternal blood, contrary to Mn concentration, which was significantly higher in cord blood than in maternal blood at delivery. This exploratory study is the first one performed in Benin, which assessed blood concentrations of toxic (Pb and Cd) and trace elements (Zn, Mn and Cu) in pregnancy prospective mother-child cohort. These findings suggest relatively high levels of exposure to Pb and Cd during pregnancy in this population of pregnant women.

1331

LOCAL PERCEPTIONS OF SEASONALITY AND REPORTED WATER CONTACT BEHAVIOR IN THE SAHEL: IMPLICATIONS FOR SCHISTOSOMIASIS TRANSMISSION

Andrea J. Lund[1], Omar Sow[1], Susanne H. Sokolow[2], Andy Chamberlin[2], Isabel J. Jones[2], Nicolas Jouanard[3], Gilles Riveau[3], David Lopez-Carr[4], Giulio A. De Leo[2]

[1]Stanford University, Stanford, CA, United States, [2]Stanford University, Hopkins Marine Station, Pacific Grove, CA, United States, [3]Espoir Pour La Sante, Saint Louis, Senegal, [4]University of California, Santa Barbara, Santa Barbara, CA, United States

Across endemic areas of sub-Saharan Africa, hundreds of millions of people acquire infections of schistosomiasis by simply being in contact with water. This exposure is often tied to mundane tasks such as washing laundry, irrigating crops and bathing, especially in rural areas where improved water sources are scarce and agricultural livelihoods common. Environmentally, the schistosome life cycle thrives in the waters that support human food security because stagnant water is prime habitat for the aquatic intermediate host snails. This environmental risk for acquiring schistosomiasis often fluctuates with seasonal changes in temperature and rainfall. Seasonal changes in the human behaviors that lead to exposure are less well-understood. In this study, focus group discussions were used to examine how perceptions of local environmental characteristics and their seasonality affect how people interact with their freshwater resources in northern Senegal. Focus group participants associated the

risk for schistosomiasis with increased temperatures on both seasonal and daily bases. They also reported altering their water contact behavior based on their perceptions of water quality, which often deteriorates during the rainy season. When perceived water quality is low, people reduce certain water contact activities, such as bathing and washing. These perceived seasonal decreases in water quality, are explained locally by reduced need for irrigation and growth of aquatic vegetation during the rainy season. Despite the relatively sophisticated local understanding of schistosomiasis transmission and the adoption of potentially protective behaviors, participants also expressed resignation at the inevitability of exposure because of the pervasiveness of schistosomiasis in the environment. The timing and targeting of environmental interventions to control schistosomiasis in this hyper-endemic region may benefit from understanding how local perceptions and livelihoods influence water contact behaviors and interact with the known ecological determinants of schistosomiasis transmission.

1332

CHEMICAL AND MICROBIOLOGICAL CONTAMINATION OF DRINKING WATER IN PERUVIAN HOUSEHOLDS WITH INFANTS

Miranda J. Delahoy[1], Mia Mattioli[1], Jackie Knee[2], Forest Altherr[1], Rebecca Hodge[1], María del Rosario Jaramillo Ramírez[3], Alisson Zevallos-Concha[4], Priya E. D'Souza[1], Parinya Panuwet[1], Carlos Culquichicón[4], Lilia Cabrera[5], Dana Boyd Barr[1], P. Barry Ryan[1], Andres G. Lescano[4], Joe Brown[2], Robert H. Gilman[6], Karen Levy[1]

[1]Emory University, Atlanta, GA, United States, [2]Georgia Institute of Technology, Atlanta, GA, United States, [3]EsSalud Piura, Piura, Peru, [4]Universidad Peruana Cayetano Heredia, Lima, Peru, [5]Asociación Benéfica PRISMA, Lima, Peru, [6]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

In June-July 2016 we collected water and stool specimens from 96 households with infants enrolled in a cohort study in Piura, Peru. At visit 1 we collected 15- and 100-ml water samples from the primary source of drinking water. At visit 2 (4-7 days later) we collected a stool sample from the study infant and recorded diarrhea symptoms. The 100 ml samples were tested for *E. coli* on the day of collection using the IDEXX Colilert method. The 15 ml water samples were analyzed using inductively-coupled plasma mass spectrometry to quantify arsenic with a detection limit of 1 µg/l. Stool samples were assayed for bacterial, viral, and parasitic enteropathogens using the Luminex Multiplex Gastrointestinal Pathogen Panel. Arsenic was detected in half of the water samples; 32% were positive for *E. coli*. 24 samples (25%) exceeded the World Health Organization arsenic limit of 10 µg/l. The maximum arsenic concentration detected was 15 µg/l. *E. coli* and arsenic were each found in samples from all types of primary drinking water sources (piped water inside the house, outside the house, or from a neighbor; protected and unprotected wells; public water basins; and water bought in bottles or from motorbikes/trucks). Of the 94 infants available for follow-up, 13 (14%) had diarrhea in the 4-7 days between visit 1 and visit 2 and 64 (68%) had an enteropathogen detected in stool at visit 2. Having *E. coli* in drinking water at visit 1 was not significantly associated with diarrhea or enteropathogen detection at visit 2. Infants from households in which the water sample had >10 µg/l of arsenic had higher odds of diarrhea at visit 2; the difference was not significant (OR: 3.00; 95% CI: 0.89-10.06). Eleven infants who were still breastfed did not receive drinking water in the week before visit 1. These infants had significantly lower odds of having an enteropathogen detected in stool at visit 2 compared to the infants who received drinking water in the week before visit 1 (OR = 0.22; 95% CI: 0.06-0.82), but lower odds of diarrhea were not observed. Drinking water contamination in a variety of water source types may pose a risk of acute and/or long-term adverse health outcomes in infants in Piura, Peru.

1333

EVALUATING THE EFFICACY OF POINT OF USE WATER FILTRATION UNITS IN VILLAGES THROUGHOUT FIJI

Nathan Tintle[1], Adam Heynen[1], Sarah Brokus[2], Randall Wade[2], Aaron Best[2]

[1]Dordt College, Sioux Center, IA, United States, [2]Hope College, Holland, MI, United States

Over 50% of the permanent population in the country of Fiji does not have regular access to clean drinking water. A water quality intervention strategy was developed for Fiji, which includes the installation of hollow fiber membrane filter bucket systems. Residents that received filtration systems were trained at the installation and at follow up visits. The residents were trained in both the proper use of filters and basic hygiene practices, in line with WHO standards. This strategy was recently adopted by the Fiji Ministry of Health, with a goal of country wide implementation by 2023. To date, five economic and health outcomes have been tracked in 511 households to evaluate the efficacy of this strategy. At the time of filter installation, all households were surveyed inquiring about the prior 14-28 day period, and then again between 19 and 224 days later (mean=66 days). When comparing installation to follow-up, diarrhea related medical costs reduced by an average of FJD$10.16/month, drinking water expenses reduced by FJD$1.82/month, and the average adult worked an additional 0.1 days/month. Among the 351 households with children under 18, 2-week diarrhea prevalence reduced from 13.0% at installation to 1.4% at follow-up. General linear and logistic mixed-effect models were used to adjust for seasonal and spatial variation, household size and time between installation and follow-up measurements. Changes in economic and health outcomes from installation to follow-up were highly statistically significant ($p<0.001$ in all cases), in both unadjusted and adjusted models. Future work entails evaluation in other countries and contexts, long-term health monitoring and comparison to alternative water quality interventions. These continued efforts will confirm comparative advantages, long-term health impact and economic sustainability of the intervention.

1334

WHAT'S IN THE WATER? AN OBSERVATIONAL AND MICROBIOLOGICAL ANALYSIS OF RESTAURANTS IN IQUITOS, PERU

Jessica Magdeburger[1], Linh Tran[1], Ricardo Abadie[2], Rosa Burga[2], David Craft[1]

[1]Pennsylvania State Hershey College of Medicine, Hershey, PA, United States, [2]Naval Medical Research Unit-6, Lima, Peru

Foodborne illness is a global problem estimated to affect 1 in 10 people worldwide. This correlates to 600 million people per year, with 420,000 deaths annually. Previous studies conducted in restaurants in Iquitos, Peru on food preparation and hygienic practices of local restaurants demonstrated that enteric organisms contaminate the kitchens of some restaurants. In continuation of this longitudinal study, we hypothesized the sink as a potential source of contamination. Thirteen restaurants were identified, nine of which were surveyed during previous years. Kitchen surfaces with highest probability of contamination were measured by distance from the sink to the sampled surface. The presence of coliforms (*Escherichia coli* and *Klebsiella* spp.) and pathogenic bacteria (*Salmonella* spp., *Shigella* spp., and *Aeromonas* spp.) was assessed by microbiological culture. In addition, observational surveys were performed assessing hygienic standards and sanitation practices within three areas of the restaurant (kitchen, restroom, and dining space). Results were compiled via a numerical grading system with each area receiving an average score. While the majority of surfaces showed presence of coliforms (104/139 surfaces, 74.8%), there was no significant relation between the presence of coliforms and average minimum distance to the sink ($p = 0.916$). *Aeromonas* spp. was the most common bacterial isolate and was significantly more prevalent in restaurants with lower average kitchen

(p = 0.028) and overall restaurant (p = 0.038) sanitation scores. While not statistically significant, the presence of *Aeromonas* spp. also trended toward lower average minimum distances to the sinks (p = 0.061). *A. hydrophila* is a human pathogen found in water that produces virulence factors linked to gastroenteritis, cellulitis, and septicemia. Since humans may acquire *Aeromonas* spp. via ingestion of contaminated raw foods and water, it is possible that water from restaurant sinks could contribute to foodborne illness in this area. Future studies may assess prevalence of *A. hydrophila* associated with diarrheal disease in this region.

1335

THE ROLE OF PREVALENCE OF WATERBORNE INFECTIONS ON THE REGRESSIVE EFFECTS OF INCOME DISPARITY IN ECUADOR

Cesar P. Montalvo, Anuj Mubayi, Carlos Castillo-Chavez

Arizona State University, Tempe, AZ, United States

Approximately 2.1 billion people in our planet (29% of the world population) are still vulnerable to water-related diseases, commonly referred as diseases of poverty, with Latin America accounting disproportionately higher burden: 51% of the region does not have free from contamination water. This paper uses dynamic mathematical models incorporating network of water distributions in Ecuador such as natural sources, (e.g. rivers, lakes, etc.) and tankers, commonly used as direct sources of water in developing countries. The aim is to study how population income disparity are altered as changes in prevalence of water borne diseases. The modeling framework takes into account socio-demographic factors, economic characteristics (such as income inequality) of the population, distribution of water infections, transmission pathways and available information from national public surveys from Ecuador, to address the question. Results present a framework to construct alerts to recognize the increase in inequality due to changes in infections. Also, inequality increases with more infections but the rate of increase slows down with appropriate income interventions. The results from these models provide elements to construct policies to potentially decrease waterborne disease transmission in environments with economic stress and consequently, avoid widening the disparity gap.

1336

MICROBIOLOGICAL EVALUATION OF WATER QUALITY AND ANTIMICROBIAL RESISTANCE PROFILE IN RIVERS OF RURAL AND URBAN BAHIA, BRAZIL

Vanessa T. Moretto[1], Soraia M. Cordeiro[2], Luciano K. Silva[1], Rafael Ponce-Terashima[3], Patricia S. Bartley[3], Ronald E. Blanton[3], Mitermayer G. Reis[4], Lúcio M. Barbosa[5]

[1]Oswaldo Cruz Foundation, Bahia, Salvador, Brazil, [2]Federal University of Bahia, Salvador, Brazil, [3]Case Western Reserve University, Cleveland, OH, United States, [4]Oswaldo Cruz Foundation, Bahia, Canela, Salvador, Brazil, [5]Bahiana School of Medicine and Public Health, Salvador, Brazil

Natural water bodies are important contributors to the dissemination of antibiotic resistance. Multiple factors facilitate the selection of resistant bacteria in this environment and therefore represent a potential risk to human health. We evaluated the antibiotic resistance profile for *Enterobacter cloacae*, *Escherichia coli* and *Klebsiella pneumoniae* isolates from a rural river system and three urban lakes in the state capital Salvador, Bahia Brazil. Coliform counts were made by Coliscan® culture, and water was then screened for resistant *Enterobacteriacea* on MacCokey agar with cefotaxime or imipenem. Selected *Enterobacteriaceae* were identified by MALDI-TOF and antibiotic profiles by Vitek 2. Antimicrobial resistance genes were detected by PCR for the most frequent carbapenemases and β-lactamases. Mean total coliform count for Jenipapo was 203 CFU/mL. For the urban sites Dique do Cabrito, Dique do Tororó, Abaeté Lagoon had 331, 145 and 145 CFU/mL, respectively. All sites had enterobacteria resistant to the antibiotics screened. *E. cloacae* was the most frequent resistant enterobacteria found. By Vitek, resistance to ampicillin sulbactam was most in all locations. Carbapenem resistance in one *K. pneumoniae* isolate (Dique do Cabrito) and one *E. cloacae* (Dique do Tororo). One *E. coli* and one *K. pneumoniae* were resistant to ciprofloxacin (Dique do Cabrito) and two *E. cloacae* resistant to gentamicin (Abataé Lagoon). There was no resistance to amikacin or tigecycline in any location. By PCR, 63% of the selected *Enterobacteriaceae* presented with genes for carbapenemases and 20% produced beta-lactamases. ESBL *blaCTX-M* enterobacteria was found in all locations and *blaTEM* only in Dique do Cabrito. Enterobacteria with carbapenemases *blaOXA-48*, *blaVIM*, *blaSPN* from Dique do Cabrito and Jenipapo river system; *blaOXA-48*, *blaVIM*, *blaSPN*, *blaIMP and blaNDM* were found in Dique do Tororo and Lagoa do Abaete. Surface waters of both rural and urban areas pose a significant risk due to the degree of fecal contamination and abundance of enterobacteria resistant to essential antibiotics to treat human and animal infections.

INSTITUTIONALIZING INFECTION PREVENTION AND CONTROL PRACTICES IN HEALTH FACILITIES IN LIBERIA FOLLOWING THE EBOLA EPIDEMIC

Allyson R. Nelson[1], Anne Fiedler[1], Topian Zikeh[1], Nancy Moses[1], Chandrakant Ruparelia[2], Lolade Oseni[2]

[1]Jhpiego, Monrovia, Liberia, [2]Jhpiego, Baltimore, MD, United States

Ebola virus disease (EVD) swept through Liberia in 2013-2015, infecting four percent of the health workforce and causing the death of nearly 200 health workers. Poor infection prevention and control (IPC) practices in health facilities and communities facilitated the rapid spread of EVD. The Ministry of Health (MOH) introduced IPC standards in 2015 to benchmark adherence to IPC practices and certify a health facility safe to provide routine care. Through OFDA, KOICA, and USAID funding, Jhpiego worked with the MOH to achieve and maintain adherence to IPC standards in over 200 health facilities through training, infrastructure upgrades, supply provision, and monthly supervision and mentoring visits from 2015 - 2017. Jhpiego assessed health facility adherence to IPC standards four times from March 2015 - Dececember 2017. Hospitals, health centers, and clinics were sampled from 8 of 15 counties using stratified random sampling. At each facility, trained clinicians and MOH supervisors used the 52-item checklist to verify IPC standards in: administrative controls, supply & equipment, staff health, screening, isolation, WASH, and utilization of personal protective equipment. Facility score was the average of all category scores; county score was average of all facility scores. In March 2015, average county score was 42% (range: 22% to 67%) By November 2015, average score increased to 80% or above for all eight counties, meeting the 80% national target. Health facilities maintained high adherence to IPC practices in 2016 and 2017, with average scores of 78% (in 4 of 8 sampled counties) and 82% (in 3 of 8 sampled counties), respectively. No health worker contracted EVD in supported facilities. These results show rapid gains in adherence to IPC guidelines and maintained compliance years after the immediate threat of EVD receded. Maintaining high adherence to IPC practices requires continued supervision and mentoring focusing on safe provision of health services, using a checklist to benchmark performance. This approach could be adapted to other countries to improve IPC practices and prevent the spread of infection in health facilities.

1338

EPIDEMIOLOGICAL PROFILE OF PEOPLE WITH CHOLERA ACCORDING TO THE CHARACTERISTICS OF HEALTH ZONES: DEMOCRATIC REPUBLIC OF THE CONGO

Sandra T. Musungayi[1], Gisele M. Mvumbi[2], Vitus L. Okitolonda[3], Didier K. Bompangue[4], Jean Jacques M. Muyembe-Tamfum[5]

[1]National Institute of Research Biomedical, Kinshasa, Democratic Republic of the Congo, [2]Kinshasa School of Public Health/FELTP, Kinshasa, Democratic Republic of the Congo, [3]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, [4]Unité de recherche et

de formation/ Ecologie des maladies infectieuses, aléa et gestion des risques; Faculty of Médecine, University of Kinshasa, Kinshasa, Democratic Republic of the Congo, [5]Institut National de Recherche Biomedicale, Kinshasa, DRC; Faculté de Médecine, Université de Kinshasa, Kinshasa, Democratic Republic of the Congo

Cholera is major public health problem because of it sever mortality on the affected persons ;in epidémic regions 80% of cases notify by OMS in the world plan comes from sub_sahara africa . in DRC, the profil of infected people with cholera is less known; and strategies to prevent it by vaccine campaign is wrongly done. To determine different profiles of people affected by cholera. A retrospective analytical study was conducted in 17 health zones of the city of Kinshasa Province. Active data collection of suspected cholera cases identified between 2000-2016 was made based on national registries available in the 17 selected areas. These data were organized in excel spreadsheets with variables year, week, health zone, age, sex, occupation for the comparison between the groups and proportion; the statistics of the tests (chi square and Fisher test) were carried out using the SPSS software version 21 for each evolutionary period. The proportions of each variable were calculated with their 95% fixed confidence interval. Traders, fishermen, pupils, students, farmers, travelers and drivers are the most affected in endemic areas with a proportion of 78.5% (95% CI: 75.9-80.8). The most affected age group is 5-14 years old with 30% (95% CI : 29,5-31,1) in endemic areas and 25.7% (95% CI : 22.9%-28.8%) in non-endemic areas. The proportion were respectively 28.7%(95% CI : 27.3-307), 20%(95% CI : 27.1-29.3) and 25.9%(11.5-44.7) in the evolutionary phases of lull, epidemic peak and restart endemic areas in the age group of 5-14 years old. The results of this study remain a challenge because the strategy will be applied in terms of age and other aspects. A multidisciplinary approach is essential to prevent cholera.

1339

DEADLY PIPES: A STUDY ON THE DIFFUSION OF CHOLERA TROUGH PIPED WATER SYSTEMS IN THE YOVI RIVER VALLEY, TANZANIA

Maria T. Giordani[1], Giovanni Donadelli[2], Lilian Kalungwana[3], Tommaso Manciulli[4], Enrico Brunetti[5], Kezia Bertoldo[2], Beatrice Accordini[2], Sergio Beraldin[6]

[1]Infectious and Tropical Disease Department, san Bortolo Hospital, Vicenza, Italy, [2]Associazione Bertoni Cooperazione e Sviluppo, Verona, Italy, [3]Msange Health Center, Msange, Kilosa District, Morogoro Region, United Republic of Tanzania, [4]Department of Clinical, Surgical, Diagnostic and Pediatric Sciences, University of Pavia, Pavia, Italy, [5]Unit of Infectious and Tropical Diseases, San Matteo Hospital Foundation, and Department of Clinical, Surgical, Diagnostic and Pediatric Sciences, University of Pavia, Pavia, Italy, [6]Department of Environmental Engineering, Trento University, Trento, Italy

With more than 4000 cases yearly, cholera is hyperendemic in Tanzania and many cholera epidemics are reported every year in the resource-poorest areas of the country. We report a brief cholera epidemic in the Yovi river valley, Kilosa district, Morogoro region, Tanzania. This area is served by a piped water system, built as a European community project in 2014. We analyzed the geographical distribution and the timing of microbiologically confirmed cases admitted to local health centers (Msange and Kisange) to explore a possible role of the piped water system in the diffusion of cholera cases. A total 76 bacteriologically confirmed cases were admitted to the two wards, either with medium (68.4 %) or severe (31.5 %) dehydration. One patient (1.3%) died. The first cases of cholera were detected on November 3rd, 2016, in patients from Msowelo village, which is close to the river source. The last cases were detected on January 6th, 2017 in the Madizini village, about 20 miles from the source. Interestingly, the first group of patients was reported to drink and use the river water but the second wave of cases involved people using tap water in Msolwa, Madizini, and Kisange. The geographical distribution of the cases shows the spread from Msowelo to the other villages of the valley along the net of water distribution. In the summer of 2017 a study performed on the Yovi aqueduct and quality of piped water by the Department of Environmental Engineering, Trento University, Trento, Italy, showed a high contamination rate of the piped water by coliforms due to the close contact with latrines and waists. Our study confirms that systems for the distribution of piped water do not prevent the diffusion of cholera in rural areas if the water supply system is not maintained on a regular basis. In such settings, piped water could actually favor the epidemic.

1340

EVALUATION OF THE EFFECTIVENESS OF BUCKET CHLORINATION IN CHOLERA OUTBREAKS

Gabrielle String, Daniele Lantagne

Tufts University, Medford, MA, United States

Bucket chlorination is a commonly implemented intervention for emergency water treatment employed during cholera outbreaks where agents stationed near a water source dose beneficiaries' water containers with chlorine. Guidelines provide two different recommendations for chlorine dosage: a fixed dosage (either 2 mg/L for low turbidity or 4 mg/L for high turbidity) or a variable dosage that provides a free chlorine residual (FCR) of 0.5 mg/L 30 minutes after dosing. To understand the effectiveness of these guidelines and the factors that impact their implementation, we are investigating bucket chlorination in both a laboratory study and field evaluations.In the laboratory, we are assessing the inactivation of *Vibrio cholerae* in the aqueous phase by treating with three different chlorine types at the recommended dosages. To challenge the recommendations, we will be testing in prepared waters of varying turbidity, total organic carbon concentration, and pH. Results, expected Summer 2018, include: 1) whether recommended dosages inactivate *V. cholerae;* 2) whether recommended dosages can maintain a 0.2 mg/L FCR 24 hours after treatment; and, 3) what dosages can achieve a 2 log reduction in *V. cholerae*. Field evaluation protocols for assessing bucket chlorination in cholera outbreaks have been developed to understand: the implementation modalities of response organizations, the effectiveness of bucket chlorination in meeting program goals, and the perceptions of the intervention by both program staff and beneficiaries. To accomplish this aim, a mixed methods protocol including key informant interviews, focus group discussions, and household surveys will be conducted. Additionally, drinking water samples will be collected for microbiological and FCR testing. Two field evaluations will occur in the Democratic Republic of Congo and Bangladesh in Summer 2018.This presentation will provide laboratory data on bucket chlorination efficacy against *Vibrio cholerae* and preliminary results from field evaluations. These results will provide the basis for the development of recommendations to existing guidelines.

1341

VALIDATION OF MOLECULAR ASSAYS FOR THE DETECTION OF *SALMONELLA TYPHI* AND *S. PARATYPHI* A IN ENVIRONMENTAL SAMPLES

Ashutosh Wadhwa[1], Shanta Dutta[2], Yuke Wang[1], Milagros Aldeco[1], Goutam Chowdhury[2], Renuka Kapoor[1], Asish Mukhopadhyay[2], Christine L. Moe[1]

[1]Emory University, Atlanta, GA, United States, [2]National Institute of Cholera and Enteric Diseases, Kolkata, India

Enteric fever is a severe systemic infection caused by *Salmonella enterica* serovar Typhi (ST) and *Salmonella enterica* serovar Paratyphi A (SPT). In order to study risk of exposure to ST and SPT a large exposure assessment study in Kolkata, India. Quantitative microbial risk assessment (QMRA) requires quantitative estimates of exposure to the pathogens of interest. Here we present, results from methods validation studies to quantitatively detect both ST and SPT by PCR in a range of relevant environmental samples. Our goals were to evaluate sample concentration and DNA extraction methods in order to optimize the limit of detection of ST and SPT in environmental samples by real-time PCR. Briefly, 10^9 cells/mL from

bacterial culture in 10-fold serial dilution were used to spike drinking water, pond water, sewage influent, soil, cucumber and tomatoes. Three methods to concentrate ST and SPT from liquid samples were evaluated: membrane filtration (50-100mL), polyethylene glycol (PEG) precipitation (500 mL) and ultrafiltration (5 - 100 L) followed by PEG precipitation. After concentration, total DNA was extracted using Qiagen DNeasy extraction kit. Samples were tested by PCR in triplicate using a Taqman-based real-time PCR platform and primers described by Nga et al 2010. Extrapolated data using standard curves from membrane filtration experiments, suggested that for most of the pathways range of detection was 10^3 to 10^9 cells/mL. PEG precipitation of sewage samples gave better recovery than membrane filtration; as indicated by an average 6 Ct difference between the two methods. Positive Ct values (22-30) were obtained on 5 and 100L samples concentrated by ultrafiltration. As assays do not include an enrichment step, they can provide quantitative estimates of the target pathogens in relevant food and environmental samples and can be used to inform "dose" estimates in QMRA analyses. Next steps include testing environmental samples in Kolkata, and developing and validating concentration and detection methods for ST and SPT in street food, dairy products, and surface swabs from public toilets.

WATER, SANITATION, AND HYGIENE MOBILE HEALTH (MHEALTH) MESSAGES AS AN INNOVATIVE TOOL TO FACILITATE BEHAVIOR CHANGE: RANDOMIZED CONTROLLED TRIAL OF THE CHOBI7 MHEALTH INTERVENTION

Christine Marie George[1], Fatema Zohura[2], Shirajum Monira[2], Elizabeth Thomas[1], Tasdik Hasan[2], Tahmina Parvin[2], Maynul Hasan[2], Khaled Hasan[1], Mahamud-ur Rashid[2], Md. Sazzadul Bhuyian[2], Peter J. Winch[1], Jamie Perin[1], Alain Labrique[1], Kelsey Zeller[1], Farzana Begum[2], Fosiul Alam Nizame[2], David A. Sack[1], R. Bradley Sack[1], Munirul Alam[2]

[1]Johns Hopkins University, Baltimore, MD, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Diarrhea is the second leading cause of death in young children globally. Furthermore, household members of diarrhea patients are at a much higher risk of developing diarrheal diseases (>100 times for cholera) than the general population during the one week period after the diarrhea patient presents at a health facility. This is likely because of poor WASH practices in the home. The time patients and their caregivers spend at a health facility for the treatment of severe diarrhea episodes presents the opportunity to deliver WASH interventions when perceived severity of diarrheal diseases and benefits of water treatment and handwashing with soap is likely the highest. Effective scalable WASH interventions are urgently needed to reduce diarrheal diseases globally. Our research group recently developed the Cholera-Hospital-Based-Intervention-for-7-Days (CHoBI7, "picture" in Bangla), a WASH intervention which promotes handwashing with soap and water treatment to diarrhea patients and their household members in a health facility setting. Our recent randomized controlled trial (RCT) in Bangladesh of CHoBI7 demonstrated this WASH intervention was effective in significantly reducing symptomatic cholera in diarrhea patient households, and led to sustained improvements in WASH practices over time. Building on this work, we are currently conducting a second RCT evaluating the impact of Mobile Health (mHealth) messages as a low cost scalable approach to reinforce the CHoBI7 WASH intervention delivered in a health facility setting to diarrhea patient households. This study is being conducted in collaboration with the Bangladesh Ministry of Health and Family Welfare. This is the first RCT to our knowledge evaluating the efficacy of sending mHealth messages to households to increase WASH behaviors. Our initial findings have shown that the CHoBI7 mHealth intervention is effective in significantly improving household water quality and increasing observed handwashing with soap at stool and food related events during the one week high risk period for diarrhea patient household members and 1 month after discharge from a health facility.

VESICLE FORMATION AND ADP-RIBOSYLATION FACTORS ASSOCIATED WITH TICK-BORNE FLAVIVIRUS INFECTION OF *IXODES SCAPULARIS* (BLACK-LEGGED TICK) SALIVARY GLAND CULTURES

Jeffrey M. Grabowski[1], Tyler G. Lewy[2], Elizabeth R. Fischer[3], Danielle K. Offerdahl[1], David W. Dorward[3], Marzia Zendali[1], Marthe VanSickle[1], Marshall E. Bloom[1]

[1]Biology of Vector-Borne Viruses Section/Laboratory of Virology/Rocky Mountain Laboratories/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Hamilton, MT, United States, [2]Laboratory of Virology and Infectious Disease/The Rockefeller University, New York, NY, United States, [3]Microscopy Unit/Research and Technologies Branch/Rocky Mountain Laboratories/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Hamilton, MT, United States

The tick, *Ixodes scapularis*, transmits a number of pathogens, including *Borrelia burgdorferi* and tick-borne flaviviruses (TBFVs). TBFV infections cause thousands of human encephalitis cases worldwide each year. In the US, confirmed human infections with Powassan virus (POWV) have a fatality rate of 10-30% and are increasing. The attenuated Langat virus (LGTV) is often used as a convenient experimental TBFV model. The tick salivary glands (SGs) serve as the primary organ barrier to TBFV transmission. Recent optimization of TBFV growth in *ex vivo* tick organ cultures allows a deeper understanding of virus biology in viable organs. Information on host proteins involved in TBFV infection is limited. ADP-ribosylation factors (ARFs) are involved in vesicle formation and transport in mammalian cells. ARFs have a role in mosquito-borne flavivirus infection but their role is unknown in TBFV infection. The goals of this study were to identify (1) vesicle formation with TBFV-like particles in SG cultures from blood-fed and unfed ticks and (2) the association of ARF1 and ARF4 in TBFV infection in human cell, tick cell and SG cultures of the two different physiological states. Using transmission electron microscopy, vesicle formation with LGTV-like particles was only observed in SGs from unfed ticks. Using small molecule and siRNA/dsRNA-mediated transcript knockdown assays, our results indicated that human ARF1 and ARF4, and their predicted tick orthologs are critical for TBFV replication in *in vitro* human and tick cells. However, transcript knockdown impact on POWV replication differed between *ex vivo* SG cultures from blood-fed and unfed ticks. This data suggests a complex relationship between the tick's physiological state and TBFV biology, especially in an organ critical for TBFV transmission. Future research may include similar studies in TBFV-infected ticks to determine effect on TBFV infection and transmission. This research helps to identify host proteins as potential targets for countermeasure development against TBFV infection and transmission. This research was supported by the Intramural Research Program of the NIH, NIAID.

LOW VACCINATION COVERAGE AND *AEDES ALBOPICTUS* AS POTENTIAL VECTOR OF TRANSMISSION OF YELLOW FEVER IN CAMEROON: RESULTS OF AN INVESTIGATION FOLLOWING POSITIVES CASES IN THREE HEALTH AREAS IN CAMEROON, 2017

Dorine B. Ngono[1], Basile Kamgang[2], Corlins Ndode[3], Céline Tchida Mairousgou[1], Christian Moundjoa[1], Elysée Nchoutpouen[4], Francky Ba Pouth Baonga[3], Els Mathieu[5], Alain Georges Etoundi[6]

[1]Cameroon Field Epidemiology Training Program, Yaounde, Cameroon, [2]Centre for Research in Infectious Diseases, Yaounde, Cameroon, [3]Expanded Program of Immunization, Ministry of Public Health Cameroon, Yaounde, Cameroon, [4]Organisation de Coordination pour la lutte contre les Endémies en Afrique Centrale, Yaounde, Cameroon, [5]Workforce and Institution Development Branch, Division of Global Health Protection Center for Global Health, Centers for Disease Control and Prevention,

Atlanta, GA, United States, [6]Department for Disease Control, Epidemics and Pandemics, Ministry of Public Health Cameroon, Yaounde, Cameroon

Because Cameroon is at risk of yellow fever (YF), national preventive vaccination campaigns are regularly conducted targeting people aged 9 months and older. Despite vaccine coverage of 85% during the last campaign in 2015, cases are continuously reported. In 2017, four cases were confirmed in three health areas. We investigated to confirm the epidemic, assess vaccination coverage, evaluate the surveillance system and identify the vector. We conducted active case finding in health facilities (HF) and the community using the standard YF case definition. Using cluster sampling, 321 households were selected and vaccination status of one adult per household was assessed. With structured questionnaires, we collected data on socio-demographics, and reasons for non-vaccination. Logistic regression identified factors associated with vaccination. An entomological survey in 173 randomly selected households identified the potential vectors involved. We also assessed surveillance system in 12 conveniently selected HF around the confirmed cases. No additional suspected case was found, and 3 of the 4 cases were traced with case fatality rate of 33.3%. One case was vaccinated. Among the 271 adults interviewed, vaccine coverage was 53% [143/271, 95% CI: 46.3-58.4]. Lack of information about the vaccination campaign (65%,51/79), absence during vaccination campaigns (22%,17/79) were the main reasons for non-vaccination. International trips [OR=3.9, 95% CI: 1.5-10.5], knowing how to guard against YF [OR=1.81, 95% CI: 1.03-3.36] and where to receive vaccination [OR=2.1, 95% CI: 1.2-3.7] were independent predictors of vaccination. *Aedes albopictus* was found in 99% of the households with a mean pupae index of 1.61. No other known YF's vector was found. Abandoned containers were the most productive breeding sites (65%, 11/17). The mean acceptability of the surveillance system was 82.5%. With low vaccination coverage, the risk of outbreak remains. We recommend mass education on YF prevention, and on the risk related to waste accumulation around homes. Otherwise, further studies to identify if *Aedes albopictus* could transmit YF should be conducted.

1345

CYTOKINE PROFILE OF WEST NILE VIRUS CASES DEVELOPING CHRONIC KIDNEY DISEASE

Michael Hansen[1], Shannon E. Ronca[1], Melissa S. Nolan[1], Rodion Gorchakov[1], Rodrigo Hasbun[2], Kristy O. Murray[1]

[1]Baylor College of Medicine, Houston, TX, United States, [2]University of Texas Health Science Center at Houston, Houston, TX, United States

West Nile Virus (WNV) is endemic in the United States and the sequelae resulting from infection are of considerable public health concern. With national estimates of over 3 million prevalent cases, greater understanding of related complications is an imperative facet of clinical care. In our cohort of WNV infected participants in Houston, TX, there was a marked increase in the development of chronic kidney disease (CKD). Of 91 enrolled participants, 21 (23%) were found to have a clinical diagnosis of CKD according to Kidney Disease Outcomes Quality Initiative (KDOQI) criteria. To begin to understand how WNV relates to the development of CKD, we evaluated expression profiles for 26 different chemokine and cytokine markers in our WNV positive participants with and without CKD. Our study indicated that those with a diagnosis of CKD had a statistically significant increase in 3 distinct cytokines: INFα2, IP-10, and MIP1a. These findings are consistent with renal pathogenesis associated with infection by other RNA viruses. Importantly, these cytokine profiles are distinct from profiles in non-infectious causes of renal injury, and are suggestive of specific cell type involvement in inducing a prolonged localized inflammatory response. These results provide an important snapshot of the relationship between WNV and CKD and could serve as the basis for future studies to better predict these outcomes in a patient population.

1346

THE ROLE OF SUBSTANCE P AND NEUROKININ-1 IN TREATING WEST NILE VIRUS DISEASE

Shannon E. Ronca[1], Alan Nimmo[2], Rebecca Berry[1], Rodion Gorchakov[1], Sarah M. Gunter[1], Kristy O. Murray[1]

[1]Baylor College of Medicine, Houston, TX, United States, [2]James Cook University, Cairns, Qld, Australia

Since its introduction to the US in 1999, West Nile virus (WNV) has led to greater than 43,000 reported cases and 1,700 deaths; estimates indicate infections exceed 3 million. In survivors, up to 40% of patients will develop long-term, severe neurological complications. With no licensed vaccines and only supportive care, it is of public health importance to identify viable therapeutic options to prevent prolonged morbidity. Substance P (SP) and its receptor neurokinin-1(NK1R) have been identified as key players in neuroinflammation and we believe they may play a valuable role in the progression of WNV infection. We conducted a study in our wild-type BL6 mouse model of WNV neuroinvasive disease using a highly selective NK1R antagonist, CH123001. Mice were infected with WNV-NY99 strain at a lethal dose and monitored for signs of disease. At the onset of symptoms, mice were treated with CH123001 or mock treated with PBS. Kaplan-Meier survival curves were used to evaluate survival and time to death. Approximate viral loads and levels of SP RNA were evaluated in each group. Uninfected, age-matched controls were included to establish normal levels of SP. Treatment with CH123001 at the time of disease onset led to increased survival and prolonged time to death. While our study suggests treatment with CH123001 successfully lowered levels of SP RNA in brains, it did not appear to alter levels of WNV RNA. Nonetheless, improved outcomes were observed and may indicate a robust role of the immune response in neuroinvasive disease and death from WNV infection. This is the first example of the role of SP in WNV infection. With many NK1R antagonists already FDA approved for human use to treat nausea, this study provides evidence that this class of medication could be applied to improve outcomes during WNV infection.

1347

TISSUE EXPANSION INDUCED BASAL LAMINA MICRO-PERFORATIONS FACILITATE ARBOVIRUS SPREAD IN *AEDES SPP*. MOSQUITOES

Philip Armstrong, John Shepard, Theodore Andreadis, **Doug Brackney**

The Connecticut Agricultural Experiment Station, New Haven, CT, United States

The recent Zika virus (ZIKV) and chikungunya virus (CHIKV) epidemics highlight the explosive nature of arthropod-borne (arbo) viruses transmitted by *Aedes aegypti* mosquitoes. Understanding how these viruses are able to infect, replicate, and navigate mosquito tissues en route to transmission is paramount to modeling disease risk and developing novel control strategies. Mosquito tissues including the midgut and ovaries are encased in a proteoglycan matrix termed the basal lamina. Previous studies have demonstrated that this structure is impenetrable to virus particles, yet arboviruses are still able to bypass this matrix and infect new tissue types. We recently demonstrated that administration of a second non-infectious bloodmeal significantly shortens the extrinsic incubation period of ZIKV-infected *Ae. aegypti* by enhancing virus escape from the mosquito midgut. The mechanisms facilitating this early escape are unknown but could be due to changes in the integrity of the basal lamina after bloodmeal acquisition. To explore this hypothesis further, we used scanning electron microscopy to examine the integrity of the basal lamina of both the midgut and ovaries of recently bloodfed individuals and non-bloodfed controls. Basal lamina micro-perforations were observed in both tissue types in engorged individuals compared to the controls. Subsequently, we performed a retrograde infection assay in which ZIKV was intra-thoracically inoculated and viral replication was assayed in midguts and ovaries of bloodfed and non-fed individuals.

Immunofluorescence revealed ZIKV *Foci* in the midgut and ovaries of fed mosquitoes, but not in the controls. These findings were confirmed by RT-qPCR. Together these data suggest that the formation of micro-perforations in the basal lamina as a result of mechanical distention during bloodmeal acquisition and oogenesis facilitates arbovirus spread within mosquitoes. This study provides a mechanistic basis for enhanced arbovirus escape from the midgut and infection of the ovaries after sequential blood meals.

CHARACTERIZING THE IMMUNE RESPONSE TO RIFT VALLEY FEVER VIRUS IN MULTIPLE SPECIES AFTER NATURAL EXPOSURE OR VACCINATION WITH CHADOX1-RVF

Daniel Wright[1], Iona Taylor[1], Sumi Biswas[1], Jennifer Marshall[1], Madeleine Clark[1], John Gitonga[2], Henry Karanja[2], Vish Nene[3], Bernard Bett[3], Bryan Charleston[4], Veronica Carr[5], Gema Lorenzo[6], Alejandro Brun[6], George Warimwe[2]

[1]University of Oxford, Oxford, United Kingdom, [2]KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya, [3]International Livestock Research Institute, Nairobi, Kenya, [4]The Pirbright Institute, Pirbright, Kenya, [5]The Pirbright Institute, Pirbright, United Kingdom, [6]CISA-INIA, Madrid, Spain

Rift Valley fever virus (RVFV) primarily infects ruminants, resulting in high levels of mortality and abortion. Humans can acquire infection through infectious mosquito bites or contact with virus-contaminated tissues and fluid. Vaccines are considered the most effective tool to limit infection. However, no licensed human vaccines are available, and current livestock vaccines have significant safety concerns. We recently developed ChAdOx1-RVF, a highly efficacious viral vectored vaccine expressing the RVFV envelope glycoproteins. To help inform vaccine strategies, we have characterised the quality of the immune response to ChAdOx1-RVF vaccination in all target species. In addition, we have characterised the immune response after natural exposure which is known to illicit lifelong protection. Sheep, goats, cattle and camels were vaccinated with ChAdOx1-RVF. Sera were sampled pre-vaccination and at various time points thereafter. Human and livestock sera from natural RVFV infection were obtained in Kenya. Samples were tested using RVFV neutralising antibody assays and ELISAs detecting total IgG, IgG subclasses and IgG avidity against the RVFV envelope glycoproteins. Vaccinating livestock with ChAdOx1-RVF elicits protective antibody responses within the range of natural human RVFV infection. Total IgG titres towards either glycoprotein strongly correlated with neutralising titre in all species. The avidity of these IgG was a poor predictor of neutralising titre. The naturally acquired human antibody response is dominated by IgG1, while livestock vaccination induced both IgG1 and IgG2. Analysis is ongoing and we plan to probe the cellular response in both livestock and human trials scheduled later this year.

1349

GOT MILK? DEFINING THE LINK BETWEEN MILK AND RIFT VALLEY FEVER

Elysse N. Grossi-Soyster[1], Justin Lee[1], Samuel Muiruri[2], Charles H. King[3], A. Desiree LaBeaud[1]

[1]Stanford University School of Medicine, Stanford, CA, United States, [2]Ministry of Public Health and Sanitation, Division of Vector-Borne and Neglected Tropical Diseases, Nairobi, Kenya, [3]Case Western Reserve University, Center for Global Health and Diseases, Cleveland, OH, United States

Rift Valley fever virus (RVFV) is a zoonotic phlebovirus that primarily infects humans and livestock. RVFV is currently endemic in sub-Saharan Africa, as well as parts of the Middle East, with imported cases more recently extending into Europe and China. RVFV infection severity varies dramatically among individuals, ranging from asymptomatic cases to severe sequelae of hemorrhagic fever, multiple organ dysfunction, and meningoencephalitis. RVFV is transmitted by mosquitoes, or by direct contact with contaminated bodily fluids and tissues. Transmission method may contribute to disease severity and progression, as exposure through contact with contaminated fluids may initiate infection with a higher viral load, as opposed to that of a mosquito bite. While previous studies have included milk exposures in their analyses, their primary focus on livestock exposures has been on animal handling, breeding, and slaughter. We analyzed data from multiple field surveys in Kenya with the aim of associating RVFV exposure to raw milk exposures from common animal species. Of those with evidence of previous RVFV infection by serology (n=267), 81.7% engaged in milking livestock compared to 36.8% for 4020 co-local seronegatives ($p<0.001$, OR 2.3, CI_{95} 1.5-3.5), 86.8% seropositives consumed raw milk compared to 33.8% seronegatives ($p<0.001$, OR 10.9, CI_{95} 6.7-18.8). Individuals who milked and also consumed raw milk had greater odds of RVFV exposure than individuals who only milked animals but did not consume raw milk. Regardless of exposure type, increased risks were associated with exposure to milk sourced from cows ($p<0.001$), sheep ($p<0.001$), and goats ($p<0.001$), but not camels ($p=0.98$ for consuming, $p=0.21$ for milking). Our data suggest that exposure to raw milk may contribute to a significant number of cases of RVFV, especially during outbreaks and in endemic areas, and that some animal species may be associated with a higher risk for RVFV exposure. Livestock trade is regulated to limit RVFV spread from endemic areas, yet further interventions should be designed to educate around the risk of RVFV exposure from raw milk.

1350

WHAT IS THE BEST IMMUNIZATION STRATEGY FOR PROTECTING AFRICAN CHILDREN AGAINST INVASIVE *SALMONELLA* DISEASE?

The first typhoid conjugate vaccine (TCV) to achieve WHO-prequalification, Typbar-TCV®, stimulates high titers of long-lived serum IgG-Vi antibodies when administered as a single-dose to infants as young as age six months and offers flexibility for inclusion at different points in the Expanded Program on Immunization schedules. Epidemiological evidence to guide optimal scheduling is required. International Vaccine Institute conducted a multi country study, Typhoid Fever Surveillance in Africa Program (TSAP), in 10 countries, Burkina Faso, Ethiopia, Ghana, Guinea Bissau, Kenya, Madagascar, Senegal, South Africa, Sudan and Tanzania, to establish

the burden of Typhoid fever (*Salmonella enterica* serovar Typhi (TF)) and invasive non-typhoidal *Salmonella* (iNTS). In this secondary analysis, incidences from in infants, stratified by age and region were calculated. A total of 30.1% (37/123) TF infections and 78.9% (71/90) iNTS infections were observed in children aged <5 years. No TF and 8.9% (8/90) iNTS infections were identified in infants <9 months of age. The annual TF incidence calculated for children aged <1 and 1 to <2 years was 5 and 39 per 100,000 person-years of observation (PYO), respectively, with the highest incidence of 304/100,000 PYO observed in children aged 4 to <5 years. The annual iNTS disease incidence for the same age groups were 81, 233, and 46.2 per 100,000 PYO. Geographically, higher incidences of both TF and iNTS disease infections were observed in West African TSAP sites. The cumulative incidence of typhoid in those aged <5 years was 279/100,000 in West Africa, compared to 154/100,000 in East Africa. The iNTS incidences in individuals aged <5 years were 828/100,000 and 48/100,000 in West and East Africa, respectively. A high TF burden in children <5 years of age supports the introduction of TCV in infants at nine months of age in Africa; for iNTS disease younger age-groups should be targeted. In the future, additional vaccines to comprehensively address the burden of invasive *Salmonella* infections observed in children will potentially be required.

INCREASING ANTIBIOTIC RESISTANCE IN *SALMONELLA ENTERICA* AND *SHIGELLA* SPP. ISOLATES FROM CHILDREN UNDER-FIVE IN WESTERN KENYA, 1997-2010: INSIGHTS INTO SOURCES OF SELECTION PRESSURE FROM SURVEILLANCE IN A LOW-INCOME, RURAL SETTING

David Berendes[1], John Benjamin Ochieng[2], Jane Juma[2], Ciara O'Reilly[3], Nancy Strockbine[1], Michele Parsons[4], Kirsten Fagerli[1], Richard Omore[2], Eric Mintz[1]

[1]Division of Foodborne, Waterborne, and Environmental Diseases, Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]KEMRI-Center for Global Health Research, Kisumu, Kenya, [3]Center for Global Health, Centers for Disease Control and Prevention, Addis Ababa, Ethiopia, [4]Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States

While antibiotic resistance (AR) is a threat to public health throughout the world, longitudinal population-level AR surveillance is limited, especially in low-income settings with high burdens of enteric infections. Since 1997, the Centers for Disease Control and Prevention has collaborated with the Kenya Medical Research Institute to conduct antimicrobial susceptibility testing on 331 *Shigella* spp. and 369 non-typhoidal *Salmonella enterica* isolates from children &lt 5 years old presenting with diarrhea to sentinel clinics in rural, western Kenya. In this population from 1997-2010, we observed high *Shigella* spp. resistance to amoxicillin-clavulanic acid (AMC, 42% of isolates), ampicillin (AMP, 68%), chloramphenicol (CHL, 49%), streptomycin (STR, 91%), sulfisoxazole (SULF, 96%), sulfamethoxazole-trimethoprim (SXT, 97%), and tetracycline (TET, 88%). *S. flexneri*, was most commonly isolated (200/331), and had greater odds of AR than other *Shigella* species. For *Salmonella enterica*, resistance to AMC (32%), AMP (66%), CHL (53%), STR (67%), SULF (84%), and SXT (67%) was high. Serogroup B *Salmonella enterica* was most commonly isolated (236/369), followed by serogroup D (57/369). Both had comparatively higher odds of AR than other serogroups detected. Odds of SXT resistance in isolates of both pathogens increased with the child's age, and increased significantly over the 13-year period. *Salmonella enterica* resistance to CHL, STR, and SULF also increased significantly during this time. Despite prevalent *Salmonella enterica* and *Shigella* spp. infections resistant to AMP or SXT, patients with these infections were given AMP (or related drugs) 16% and SXT 17% of the time. Overall, despite high initial levels of resistance in 1997, population-level resistance to core drugs (such as SXT) increased over the 13-year period, especially among the most prevalent species/serogroups of *Shigella* and *Salmonella enterica* isolated from young children in a rural, low-income setting. These results highlight the potential for sustained increases in AR driven by antibiotic selection pressures in high-burden settings.

SPATIAL AND GENOMIC DATA TO IDENTIFY TRANSMISSION ROUTES OF TYPHOID FEVER IN BLANTYRE, MALAWI

Jillian Gauld[1], Peter J. Diggle[2], Alex M. Wailan[3], Franziska Olgemoeller[4], Nicholas R. Thomson[3], Nicholas A. Feasey[5]

[1]Institute for Disease Modeling, Bellevue, WA, United States, [2]Lancaster University, Lancaster, United Kingdom, [3]Wellcome Sanger Institute, Hinxton, United Kingdom, [4]Malawi-Liverpool-Wellcome Trust Clinical Research Programme, Blantyre, United Kingdom, [5]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Queen Elizabeth Hospital (QECH) in Blantyre, Malawi, experienced a sharp increase in cases of typhoid fever starting in 2011, the majority being multi-drug resistant. Despite ongoing transmission today, the dominant mechanisms of persistence remain unknown, posing a challenge for effective control interventions. Spatial patterns of genetic relatedness of clinically isolated *Salmonella* Typhi may offer insight into the mechanisms of transmission occurring, and we aimed to quantify and understand these trends in Blantyre. Beginning in 2015, *S.* Typhi isolated from cases presenting to QECH were whole-genome sequenced, and households were geo-located. Variable regions of the sequences (i.e. highly recombinant and prophage regions) were excluded, leaving 400 informative single nucleotide polymorphisms (SNPs) across isolates. Resulting pairwise SNP distances were converted into informative variables for statistical modeling using multidimensional scaling. Genetic patterns of *S.* Typhi isolates across Blantyre showed a heterogenous distribution of genotypes, with spatial correlation occurring among isolates of cases living up to 2 kilometers apart. Risk factor analyses have previously identified cooking and cleaning with river water as a potential exposure pathway for S. Typhi in Blantyre, so we then evaluated the ability of river catchment to explain the spatial patterns using a linear model with a spatial random effect, implemented in R statistical software. Results from the analysis indicate that the spatial genetic patterns seen across the city are influenced by three primary components: river catchment, close neighbors (living a maximum of 200 meters apart), and household units. Results from this study highlight the value of genomics in better understanding the complex transmission mechanisms of typhoid fever, and support control approaches targeting multiple scales of transmission, such as pairing vaccines with targeted water and sanitation interventions.

1353

COST-EFFECTIVENESS OF TYPHOID CONJUGATE VACCINE STRATEGIES IN 54 GAVI-ELIGIBLE COUNTRIES

Joke Bilcke[1], Marina Antillón[1], Zoë Pieters[1], Elise Kuylen[1], A. David Paltiel[2], Kathleen Neuzil[3], Andrew Pollard[4], **Virginia Pitzer**[2]

[1]University of Antwerp, Antwerp, Belgium, [2]Yale School of Public Health, New Haven, CT, United States, [3]University of Maryland School of Medicine, Baltimore, MD, United States, [4]University of Oxford, Oxford, United Kingdom

The World Health Organization recently recommended the programmatic use of typhoid conjugate vaccine (TCV) in endemic countries, and Gavi has pledged support for vaccine introduction. While TCV strategies are likely cost-effective in medium- to high-incidence settings, country-specific evaluations are warranted. We compared four strategies: no vaccination; routine immunisation at 9 months; or routine immunisation at 9 months with catch-up campaigns to either age 5 or 15 years. For each of 54 Gavi-eligible countries, output from an age-structured transmission dynamic model was combined with country-specific treatment and vaccine-related costs, treatment outcomes, and disability weights to estimate disability-adjusted life-years (DALYs) to identify: (1) the preferred strategy, based on the highest average net benefit for a range of willingness-to-pay

(WTP) values; (2) how certain we are about the preferred strategy; and (3) the minimum economic and epidemiological conditions under which vaccination is preferred. At a vaccine price of US$1.50 per dose and a WTP value of US$1,000 per DALY averted, routine vaccination including a catch-up campaign to 15 years of age is the preferred strategy in 46 countries. However, for half of these countries, the probability that this strategy results in the highest net benefit is <60%. Vaccination is increasingly likely to be preferred at higher rates of typhoid incidence and mortality, and at higher WTP values. While routine TCV immunisation with a catch-up campaign is preferred over no vaccination in most Gavi-eligible countries, investing in obtaining improved estimates of typhoid age-specific incidence and mortality may be valuable for many countries.

ADVERSE EVENTS FOLLOWING IMMUNIZATION WITH TYPHOID CONJUGATE VACCINE: MASS IMMUNIZATION AGAINST CEFTRIAXONE RESISTANCE TYPHOID FEVER IN HYDERABAD, PAKISTAN

Mohammad T. Yousafzai[1], Sultan Karim[1], Naveed Masood[2], Jamshed Khanzada[3], Farah N. Qamar[1]

[1]The Aga Khan University, Karachi, Karachi, Pakistan, [2]Health Dept. Govt of Sindh, Hyderabad, Pakistan, [3]DPCR, Hyderabad, Pakistan

Pakistan is facing the largest outbreak of extensive drug resistant typhoid. The outbreak started from Hyderabad and predominantly affected children less than 10 years of age. The Aga Khan University in collaboration with department of health, Government of Sindh, procured the WHO pre-qualified Typhoid conjugate vaccine (TCV), to initiate a mass immunization campaign in Hyderabad as a response to the outbreak. Door to door immunization of children 6months to 5 years of age was started in January 2018. In order to ascertain the adverse events following immunization (AEFI), a subset of children was actively followed on day 7 and 14 following the vaccination. Information about any illness, disability, hospitalization or death was collected by trained staff through a standard AEFI form translated in local language. In case of hospitalization or visit to a general physician, information on admissions, discharge, and prescriptions were obtained. Caretakers of all the vaccinees were also provided 24hrs emergency contact number to report any illness. A total of 4070 vaccinated children; 655 aged 6-12months, 851 aged 1-2 yrs, 911 aged 2-3, 836 aged 3-4 and 823 aged 4-5 yrs were actively followed and only 21, 13, 24, 16 and 22 children respectively in each of the age groups had some kind of AEFI. All of the AEFIs identified actively were mild in nature; 69/4076(1.7%) fever, 15(0.4%) diarrhea, 5(0.1%) vomiting, 3(0.07%) abdominal pain, 2(0.05%) chest infection, cough and swelling on injection site was 1(0.02%) each. Besides, out of total 32,215 doses administered there were 09(0.03%) of AEFI observed either immediately within 30 minutes of vaccination or passively reported through emergency contact number. 4/32215(0.01%) developed high grade fever, 2(0.006%) developed a rash on the whole body and severe vomiting, seizure, and swelling at the injection site were 1(0.003%) each. Typbar-TCV vaccine was found to be safe for administering in emergency situation during mass immunization campaign in Hyderabad city of Pakistan. Mild fever and diarrhea are the most frequent AEFIs. Seizure is extremely rare (1 in 32000 doses).

1355

ASSESSMENT OF IMMUNE AVIDITY TO DETERMINE THE COURSE OF DISEASE IN ACUTE AND CHRONIC STATE OF NATURAL *SALMONELLA TYPHI* INFECTION

Ayan Dey, Ju Yeong Park, Sunha Song, Ursula Panzner, Se Eun Park, Manki Song, Florian Marks

International Vaccine Institute, Seoul, Republic of Korea

An assessment of the duration of immune response to natural typhoid (TF) infection was performed as a part of Severe Typhoid in Africa (SETA) study. Immune avidity assay was used for testing serum samples of acute cases and asymptomatic controls during one year follow-up. The avidity assay is based on Vi-ELISA assay, involving antigen-antibody binding in the presence of chaotropic agent (Gu HCl). Antigen-antibody complexes present in serum of chronic infection bind strongly to Vi antigen and dissociate weakly in presence of chaotropic agent, whereas in recent infection cases, antibodies dissociate easily. This assay will help identify carriers during follow-up visits and, thus, reduce risk of unrecognized TF transmission. The Vi-avidity assay was established and internally qualified. Using avidity assay we tested serum samples from febrile cases from Ghana sites of West Africa for Vi IgG and IgM ELISA & avidity. Addition to febrile cases we also tested neighborhood healthy controls, healthy household contacts. Initial data suggests all blood culture positive and several negative samples having high anti Vi-IgM titers and anti Vi-IgG titers of >100 ELISA units. High titers were also detected in healthy neighborhood controls and house hold contacts. Interestingly many of this subjects with high Vi- antibody titers also have high antibody avidity suggesting probability of repeat infection or persistent chronic state. Samples with high IgG avidity (80-100 avidity index) may be consider as repeat infection. Samples with high IgM avidity (80-100 avidity index) may be consider as recent infection with repeat exposure. Sample with both high IgG and IgM avidity may be consider as chronic state with persistence of *S typhi*. The avidity cut off estimates were done on basis of other reports on pneumococcal and cholera natural infection studies. Further additional analysis are needed to better understand the cutoffs. Bactericidal antibodies were also tested in blood culture positive patients. High bactericidal antibody titers were detected in this subjects, suggesting antibodies generated by natural infection have functional role in killing *S typhi*.

1356

UNPRECEDENTED PNEUMONIC PLAGUE EPIDEMIC IN MADAGASCAR, 2017: CAN WE MAKE PLAGUE HISTORY?

Minoarisoa Rajerison[1], Rindra Randremanana[1], Birgit Nikolay[2], Voahangy Andrianaivoarimanana[1], Institut Pasteur Task Force Team[1], Eric Bertherat[3], Voahangy Rasofolo[1], Maherisoa Ratsitorahina[4], André Spiegel[1], Simon Cauchemez[2], **Laurence A. Baril**[1]

[1]Institut Pasteur de Madagascar, Antananarivo, Madagascar, [2]Institut Pasteur, Paris, France, [3]World Health Organization, Geneva, Switzerland, [4]Ministry of Public Health, Antananarivo, Madagascar

Yersinia pestis continues to threaten the Malagasy population with around 300 reported cases/year during September - April. In 2017, Madagascar experienced a large epidemic of Pneumonic Plague (PP). We present the epidemiological analyses of plague cases based on the official national database from the Central Laboratory for Plague (CLP, a WHO Collaborating Center) at the Institut Pasteur de Madagascar (IPM), which combined case notification forms with results from biological analyses. Cases were classified as confirmed/probable based on positive culture and/or positive qPCR (*pla, caf* 1 and *inv* genes) and/or positive rapid diagnostic tests (RDT, locally-produced by IPM) performed by the CLP. On September 11, successive deaths of unknown cause triggered an alert in a plague-free area. Plague was diagnosed by RDT in one deceased case in Antananarivo (the capital city). Subsequent investigation led to identification of 5 unnoticed suspected plague deaths that occurred during the 2 weeks before the alert, including the index case. The risk of geographic extension of the PP epidemic triggered a national and international response. Between August 1 and November 26, 2,414 clinically-suspected plague cases were reported, of which 1,878 (78%) were PP cases and 395 (16%) were Bubonic Plague (BP). Confirmed/probable cases represented 22% (418/1,878) of PP and 35% (139/395) of BP cases. Confirmed/probable cases were reported from 41/114 (36%) administrative districts. PP hotspots were mainly identified in Antananarivo and Toamasina, the main seaport. The case fatality rate was 13% for confirmed/probable and 8% for suspected cases. Rapid confirmation of cases and identification of contacts was difficult due to the urban and highly populated setting

of the epidemic and the difficulties encountered during sputum sample analyses. This epidemic led to implementation of additional molecular diagnostic tools and strengthened the country's capacities for multisectoral responses. Lessons learnt will help to improve responses for the upcoming plague seasons and highlight the need to strengthen research on plague to eliminate the disease in humans.

A REVIEW OF CONTROLLED HUMAN MALARIA INFECTION TRIALS AT THE UNIVERSITY OF MARYLAND

DeAnna J. Friedman-Klabanoff, Matthew B. Laurens, Andrea A. Berry, Mark A. Travassos, Matthew Adams, Kathy A. Strauss, Biraj Shrestha, Myron M. Levine, Robert Edelman, Kirsten E. Lyke

University of Maryland School of Medicine, Baltimore, MD, United States

Eradication of malaria will not likely succeed without an effective vaccine. Controlled human malaria infection (CHMI) is a powerful tool to evaluate potential vaccine candidates, allowing for down-selection of vaccine candidates before conducting expensive field trials. Investigators at the University of Maryland School of Medicine (UM SOM) pioneered the technique in the 1970s and continue to advance CHMI research. These advances include alternate routes of sporozoite delivery, ultrasensitive PCR diagnostics, exclusive outpatient study conduct, and heterologous CHMI. We reviewed records of 357 malaria-naïve volunteers who underwent CHMI with either the NF54 or 7G8 strain of *Plasmodium falciparum (Pf)* at our institution from 1973 until 2017. These 357 malaria-naïve volunteers experienced 406 unique CHMI events, including 60 via parenteral administration. No volunteer suffered an unplanned hospitalization or required invasive intervention related to CHMI. Among non-vaccinated volunteers, the median prepatency period (8 days) did not differ between *Pf* strains (NF54 vs 7G8) but time-to-event curves differed (p=0.033, log rank test). Real time quantitative PCR detected *Pf* infection 3.0 days earlier in non-vaccinated participants than thick smears (p &lt 0.0001). With dose optimization, administration via direct venous inoculation resulted in a similar prepatent period to mosquito bite challenge of non-vaccinated volunteers (log-rank test, p=0.17). Historical studies with NF54 showed a shorter median prepatency period of 10.8 days as compared with more recent studies (median 11.0 days, p=0.043 by log-rank test) in those who did not undergo vaccination, despite similar study conditions and mean salivary gland scores (where available). The 46-year experience of CHMI at UM SOM has advanced this model as an effective tool to winnow and optimize candidate vaccines, enabling better resource allocation, and could provide supporting data for vaccine licensure.

PRELIMINARY DATA FROM A BIOMARKER EVALUATION TRIAL AMONG NON-SEVERE FEBRILE PATIENTS IN A MALARIA ENDEMIC SETTING IN MALAWI

Camille Escadafal[1], Steffen Geis[2], Jullita Malava[3], Louis Banda[3], Hazzie Mvula[3], Jacqueline Saul[2], Aurélien Mace[1], Victoria Harris[1], Sabine Dittrich[1]

[1]FIND, Geneva, Switzerland, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Malawi Epidemiology & Intervention Research Unit, Chilumba, Malawi

Although malaria incidence has been decreasing in low- and middle-income countries (LMICs) over the past two decades, acute febrile illnesses are still a major cause of mortality and morbidity. A lack of simple, cheap rapid tests for febrile illnesses other than malaria is resulting in overtreatment with antibiotics for those who test negative for malaria, contributing to the global rise in antimicrobial resistance. Host biomarkers appear as promising tools to differentiate bacterial from non-bacterial infections in febrile patients. However, very few evaluation studies have been performed in the overall non-severe febrile population in LMICs, resulting in poor knowledge on the performance of these biomarkers in a context of high prevalence of diseases such as malaria, HIV and arbovirus infections. To address this knowledge gap, FIND is conducting a multi-center study to evaluate the performance of candidate biomarkers to distinguish bacterial from non-bacterial infections in the adult and children febrile population presenting at outpatient departments. Since April 2017, the first study site, the Malawi Epidemiology & Intervention Research Unit in Northern rural Malawi, has recruited 1000 patients. A wide range of reference tests has been performed to inform the cause of fever. Further, clinical and microbiological data of all patients with an undetermined diagnosis will be reviewed by a clinical panel to classify each patient based on the cause of fever. Complete data for the first 406 patients (57% female; 35% 2-4y; 38% 5-17y; 27% 18-65y) and corresponding preliminary results on the performance of six biomarker tests (C-reactive protein (CRP), Procalcitonin, Human neutrophil lipocalin, Myxovirus resistance protein + CRP, Heparin binding protein, Chitinase 3-like 1) are available. This study will give a preliminary overview of the performance characteristics of multiple promising biomarkers in sub-Saharan Africa when used in non-severe febrile patients. This dataset will inform subsequent product development efforts and implementation efforts to help improve non-malarial fever management and reduce overuse of antibiotics.

1359

ECONOMIC COSTS OF *PLASMODIUM VIVAX* EPISODES: A MULTI-COUNTRY COMPARATIVE ANALYSIS USING PRIMARY TRIAL DATA

Angela Devine[1], Ayodhia P. Pasaribu[2], Tedla Teferi[3], Huong-Thu Pham[4], Febrina Contantia[5], Thuy-Nhien Nguyen[4], Viet Thanh Ngo[4], Hien Tran[4], Asrat Hailu[6], Ric N. Price[7], Yoel Lubell[1]

[1]Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand, [2]Department of Pediatrics, Medical Faculty, Universitas Sumatera Utara, Medan, Indonesia, [3]The Carter Center, Addis Ababa, Ethiopia, [4]Oxford University Clinical Research Unit, Hospital for Tropical Diseases, Ho Chi Minh City, Vietnam, [5]Tanjung Leidong Health Center, Labuhanbatu Utara, Tanjung Leidong, Indonesia, [6]Addis Ababa University, Addis Ababa, Ethiopia, [7]Menzies School of Health Research, Darwin, Australia

A better understanding of the costs of *P. vivax* is needed to optimize the allocation of resources for malaria elimination. We elucidated the costs associated with vivax malaria across a range of endemic settings. Cost data were collected in the context of a multi-centered clinical trial comparing 7 and 14-day primaquine regimens in Afghanistan, Ethiopia, Indonesia and Vietnam. Patients were surveyed on days 0 and 14 to determine the costs of treatment and transportation, and the duration that they and any caregiver were unable to perform usual activities. These productivity losses were valued at one gross domestic product per capita per day. Micro-costing was used to collect the additional costs required to diagnose and treat vivax malaria. The mean (SD) total households costs ranged from US$8.4 (US$4.2) in Afghanistan to US$68.6 (US$ 66.8) in Indonesia. Across all countries, the productivity costs were the largest cost component with a median (range) of 2.5 (1-4) days for patients and 1 (0.5 - 3) day for carers. The cost of administering a G6PD RDT ranged from US$0.9 to US$13.9 and this was consistently lower than the costs of the widely-used Fluorescent Spot Test (FST), which ranged from US$13.7 to US$17.9. The cost of a Haemocue™ test to monitor for anemia ranged from US$0.2 in Ethiopia to US$1.6 in Indonesia. Screening for G6PD deficiency with an RDT was less costly than testing with FST. An episode of vivax malaria results in substantial costs to households. These costs are primarily due to productivity losses, which are often excluded from economic evaluations.

1360

USE OF MOBILE TECHNOLOGY-BASED PARTICIPATORY MAPPING APPROACHES TO GEOLOCATE HEALTH FACILITY ATTENDEES FOR DISEASE SURVEILLANCE IN LOW RESOURCE SETTINGS

Henry Surendra[1], Kimberly Fornace[1], Tommy Abidin[2], Ralph Reyes[3], Maria Macalinao[3], Gillian Stresman[1], Jennifer Luchavez[3], Riris Ahmad[4], Supargiyono Supargiyono[4], Fe Espino[3], Chris Drakeley[1], Jackie Cook[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Faculty of Medicine and Health Sciences, Universiti Malaysia Sabah, Kota Kinabalu, Sabah, Malaysia, [3]Department of Parasitology, Research Institute for Tropical Medicine, Manila, Philippines, [4]Centre for Tropical Medicine, Faculty of Medicine, Universitas Gadjah Mada, Yogyakarta, Indonesia

Identifying fine-scale spatial patterns of disease is essential for effective disease control and elimination programmes. In low resource areas without formal addresses, novel strategies are needed to locate residences of individuals attending health facilities in order to efficiently map disease patterns. We aimed to assess the use of Android tablet-based applications containing high resolution maps to geolocate individual residences, whilst comparing the functionality, usability and cost of three software packages designed to collect spatial information. Using Open Data Kit GeoODK, we designed and piloted an electronic questionnaire for rolling cross sectional surveys of health facility attendees as part of a malaria elimination campaign in two predominantly rural sites in the Rizal, Palawan, the Philippines and Kulon Progo Regency, Yogyakarta, Indonesia. The majority of health workers were able to use the tablets effectively, including locating participant households on electronic maps. For all households sampled (n=603), health facility workers were able to retrospectively find the participant household using the Global Positioning System (GPS) coordinates and data collected by tablet computers. Median distance between actual house locations and points collected on the tablet was 116m (IQR: 42 - 368) in Rizal and 493m (IQR: 258 - 886) in Kulon Progo Regency. Accuracy varied between health facilities and decreased in less populated areas with fewer prominent landmarks. Results demonstrate the utility of this approach to develop real-time high-resolution maps of disease in resource-poor environments. This method provides an attractive approach for quickly obtaining spatial information on individuals presenting at health facilities in resource poor areas where formal addresses are unavailable and internet connectivity is limited. Further research is needed on how to integrate these with other health data management systems and implement in a wider operational context.

1361

MALARIA AND RICE IN AFRICA: STILL A PADDIES PARADOX?

Kallista HC Chan, Jeff Waage, Jo Lines

London School of Hygiene & Tropical Medicine, London, United Kingdom

Due to the growing popularity of rice as a staple crop in Africa and how rice fields increase mosquito abundance, the effect of rice on malaria needs to be revisited. Previously, this relationship has been disregarded due to a phenomenon found in numerous studies called the paddies paradox, where rice does not lead to increased malaria risk despite increased quantities of malaria vectors due to better socioeconomic conditions and higher bed-net and antimalarial drug usage in rice farmers. However, since these studies, the malaria situation across Africa has changed dramatically and one can no longer assume this disproportionate distribution in malaria protective measures. Therefore, through a comprehensive literature review, we aim to reveal the true effect of rice on malaria. A search for studies that assessed the effect of rice on malaria vector quantities and/or malaria transmission was performed, and 41 studies and 3 reviews were found. As anticipated, higher malaria vector abundances, of up to 500-fold, were observed in rice-growing communities. This was seen particularly in the dominant and highly efficient vectors *Anopheles gambiae* sensu lato. Preceding the amplification of malaria interventions across sub-Saharan Africa in the early 2000s, most studies were subjected to the paddies paradox. Various hypotheses attempted to explain the paradox, including wealth creation and increased bed-net usage due to greater nuisance from higher mosquito abundance in rice communities as well as lowered anthropophily of malaria vectors due to decreased longevity and increased zoophily in rice fields. However, as the malaria situation has changed, there is some evidence that the paddies paradox no longer applies and that rice actually results in an increase in malaria prevalence. Whilst an alternative option is to advocate for intermittent irrigation, many outstanding questions remain unanswered. Nonetheless, this intimation of a recent malaria increase in rice-growing areas is a cause for concern and suggests it takes a lot more to properly eliminate malaria in sub-Saharan Africa, considering its upcoming intensification in rice.

1362

IMPROVING PROCUREMENT AND REDEPLOYMENT OF DISTRICT LEVEL MALARIA COMMODITIES USING SHORT MESSAGE SERVICE (SMS) AND WEB MAPPING IN MADAGASCAR

Haja Andriamiharisoa[1], Eliane Razafimandimby[1], Jean Pierre Rakotovao[1], Jean Eugene Injerona[1], Zo Harifetra[1], Lalanirina H. Ravony[1], Rado Randriamboavonjy[2], Jocelyn Razafindrakoto[3], Laurent Kapesa[3]

[1]Maternal and Child Survival Program/Jhpiego, Antananarivo, Madagascar, [2]Madagascar Ministry of Health, Antananarivo, Madagascar, [3]US President's Malaria Initiative, United States Agency for International Development, Antananarivo, Madagascar

Malaria remains a public health problem in Madagascar. In 2016, it was the fourth leading cause of morbidity in health centers and the fourth leading cause of hospital mortality. One issue at health facilities is stock out of malaria commodities. However, the reporting system does not allow for oversight of the monthly stock situation in health facilities. The USAID Maternal and Child Survival Program provided a simple, low-cost tool to map the monthly stock levels of key malaria commodities through structured short message service (SMS) communications by health providers in facilities. Health providers sent a text message about seven essential health commodities, containing a maximum of 30 characters including spaces. The SMSs sent by health providers were registered directly into a database host on a web server and the web-based map was updated immediately with stock-out rates. This mapping was accessible via web and viewable at district, regional and national levels with Internet connections. Mapping facilitates decision-making at all levels to develop and implement commodity recovery plans, either by replenishing at the district level or by redeploying surplus stocks from neighboring public sector health facilities. The usual wait time of 2 months to receive new stocks can be decreased by requesting commodities from neighboring centers that have overstocks of the required items. Results for the first month of implementation (January 2018) from 107 facilities in 48 districts sending SMSs demonstrated that 51% of health facilities reported a stock-out of injectable artesunate, 4% of artemisinin combination therapy and 67% of insecticide treated bednets. These results have been shared with supply chain actors to alert them of the stock-out. This intervention is expected to contribute to improved commodity availability by recommending update of commodities management procedures and manuals to prioritize the closest resources first, and prompt supply chain actors to complete the normal process to replenish stocks.

INTEGRATED DRUG EFFICACY SURVEILLANCE (IDES): THE FEASIBILITY OF USING ROUTINE CASE MANAGEMENT AND FOLLOW-UP ACTIVITIES TO MONITOR DRUG EFFICACY AND RESISTANCE IN THAILAND

Aungkana Saejeng[1], Nardlada Khantikul[1], Prayuth Sudathip[2], Suravadee Kitchakarn[2], Preecha Prempree[2], David Sintasath[3], Darin Kongkasuriyachai[4], Surasak Sawang[4], Richard Reithinger[5], Deyer Gopinath[6]

[1]Office of Disease Prevention and Control Region 1, Department of Disease Control, Ministry of Public Health, Chiangmai, Thailand, [2]Bureau of Vector Borne Disease, Department of Disease Control, Ministry of Public Health, Nonthaburi, Thailand, [3]U.S. President's Malaria Initiative, Regional Development Mission for Asia, United States Agency for International Development, Bangkok, Thailand, [4]Inform Asia: U.S. Agency for International Development's Health Research Program, RTI International, Bangkok, Thailand, [5]International Development Group, Global Health Division, RTI International, Research Park Triangle, NC, United States, [6]World Health Organization, Thailand Country Office, Nonthaburi, Thailand

Therapeutic efficacy studies (TES) are the World Health Organization's (WHO) recommended approach for national malaria programs to monitor the efficacy of antimalarial drugs. With declining malaria transmission, TES case enrollment has become challenging. In 2017, WHO and the Thai Ministry of Public Health recommended piloting integrated Drug Efficacy Surveillance (iDES) to ensure complete treatment of all cases in the context of malaria elimination. iDES integrates patient follow-up for all species with microscopy and dried blood spots (for molecular testing) as part of routine case surveillance to ensure compliance and adequate treatment outcomes. The approach included supervised radical treatment according to the national guidelines (dihydroartemisinin-piperaquine + primaquine for *Plasmodium falciparum* and mixed infection; chloroquine + primaquine for *P. vivax* and monitoring of parasite clearance during follow-up visits. Blood films were confirmed by an expert microscopist via the routine laboratory quality assurance system. Dried blood spots were collected at the time of diagnosis for detection of drug resistance markers and during each follow-up for confirmation of positive microscopic results. From May-December 2017, a total of 270 malaria cases were registered. Approximately 25% of the 88 migrant cases completed three or more follow-up visits. Among the 182 Thai cases, 78% of *25 Pf* cases (78% on day 7, 87% on day 28, 65% on day 42, and 74% on day 60) and 63% of the 156 *Pv* cases (72% on day 14, 63% on day 28, 63% on day 60, and 62% on day 90) completed three or more follow-up visits. None of the patients exhibited delayed parasite clearance. While we are currently assessing what infrastructure and resources are needed to implement iDES in a malaria elimination context, as compared to TES, our results suggest that iDES can be used to monitor radical cure of cases and drug resistance through adequate routine case management.

RISK OF EXPOSURE TO FECAL CONTAMINATION FOR ADULTS AND CHILDREN IN SLUM, NON-SLUM, AND HIGH-INCOME NEIGHBORHOODS ACROSS DHAKA, BANGLADESH USING THE SANIPATH EXPOSURE ASSESSMENT TOOL

Christine L. Moe[1], Jamie Green[1], Suraja Raj[1], Yuke Wang[1], Nuhu Amin[2], Shahjahan Ali[2], Mahbubur Rahman[2], Imrul Hasan[2], Zahidul Hassan[2], Sabrina Haque[3], George Joseph[3]

[1]Emory University, Atlanta, GA, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]World Bank Group, Washington, DC, United States

Dhaka, Bangladesh has experienced rapid population growth and challenges meeting sanitation service demands. Poor sanitation and fecal sludge management can lead to fecal contamination in the urban environment. To understand risk of exposure to fecal contamination, an assessment of 10 environmental pathways was conducted using the SaniPath Tool. Data were collected from 10 neighborhoods (6 low-income, 2 mixed-income, and 2 high-income) throughout Dhaka between April-June 2017. 1000 environmental samples were collected from shared latrines, public play areas, produce in markets, street food, open drains, flood waters, surface waters, bathing water, municipal water, and non-municipal water. Samples were analyzed using IDEXX-Colilert-24® Quanti-Tray/2000 to determine most probable number (MPN) of *E. coli*. Behavior surveys were conducted with households, school children, and community groups to understand interaction with the environment. Using Bayesian methods, the behavioral and microbiological data were used to estimate the percentage of the population exposed and mean dose of fecal exposure (*E. coli*) for each environmental pathway in each neighbourhood. For adults, consumption of raw produce was the dominant exposure pathway (i.e. makes greatest contribution to total exposure) in 6 of the 10 neighborhoods. The percentage of adults exposed to fecal contamination through ingestion of raw produce ranged from 78-99% and the mean dose ranged from $10^{4.8}$ to $10^{7.5}$ MPN of *E. coli* ingested/month. The most common dominant pathway of exposure amongst children (8/10 neighborhoods) was accidental ingestion of drain water from playing in, or passing through, open drains (up to 94% exposed; mean dose of $10^{7.8}$ MPN of *E. coli* ingested/month). Ingestion of fecal contamination via produce and street food was a high risk throughout Dhaka, while exposure to fecal contamination via municipal drinking water was mainly greater risk for those living in the south of the city. These results can guide city-wide WASH programming to prioritize interventions aimed at dominant exposure pathways and increase the potential for public health impact.

SAND BARRIERS AROUND PIT LATRINES REDUCE FECAL BACTERIAL LEACHING I0NTO SHALLOW AQUIFER: A RANDOMIZED CONTROLLED TRIAL IN COASTAL BANGLADESH

Abu Mohd Naser[1], Solaiman Doza[2], Mahbubur Rahman[2], Kazi Matin Uddin Ahmed[3], Mohammed Shahid Gazi[2], Gazi Raisul Alam[2], Mohammed Rabiul Karim[2], Mohammed Nasir Uddin[2], Mohammed Ilias Mahmud[4], Ayse Ercumen[5], Julia Rosenbaum[6], Jonathan Annis[7], Stephen P. Luby[8], Leanne Unicomb[2], Thomas F. Clasen[1]

[1]Department of Environmental Health Sciences, Rollins School of Public Health, Emory University, Atlanta, GA, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh, [3]Department of Geology, University of Dhaka, Dhaka, Bangladesh, [4]Department of Geology and Mining, University of Barishal, Barishal, Bangladesh, [5]Department of Epidemiology, University of California Berkeley School of Public Health, Berkeley, CA, United States, [6]FHI360, Washington, DC, United States, [7]Tetra Tech, Arlington, VA, United States, [8]Woods Institute for the Environment, Stanford University, Stanford, CA, United States

Pit latrines are used worldwide but present a risk to human health if fecal pathogens leach into the groundwater. We evaluated the effect of installing a sand barrier around pits to reduce the leaching of fecal indicator bacteria (FIB) into the shallow aquifer. We constructed 68 new off-set single pit latrines in Galachipa sub-district of Patuakhali district of coastal Bangladesh. We randomly assigned 34 latrines to have a 50-cm thick sand barrier under and around the pit and 34 received no sand barrier. Four monitoring wells of 20 feet depth were constructed around each pit, 1 meter from the pit edge to collect water samples at baseline and subsequent nine follow-up visits over 24 months. Samples were tested using the IDEXX Colilert method to enumerate the most probable number (MPN) of *E. coli* and fecal coliforms. We determined the difference in mean $\log_{10}$MPN of FIB counts/100ml water between intervention and control latrine well samples using multilevel linear models with random intercepts for each latrine and monitoring well and reported cluster robust

standard error. In total, 1209 water samples were tested for *E. coli* and fecal coliforms. The mean $\log_{10}$MPN counts/100ml water for *E. coli* was 1.43 for the control and 1.05 for the intervention latrines, and for fecal coliforms were 1.63 for the control and 1.25 for the intervention latrines. Compared to the control latrines' monitoring wells, the water samples of the intervention latrines' monitoring wells had a 0.38 (95% CI: 0.16, 0.59; p = 0.001) mean $\log_{10}$MPN reduction in *E. coli* and a 0.38 (95% CI: 0.14, 0.62; p = 0.002) mean $\log_{10}$MPN reduction in fecal coliforms suggesting a reduction of 27% *E. coli* and 24% fecal coliforms. Our data suggest that a sand barrier around and under the pit reduced groundwater fecal contamination in context of shallow aquifers.

1366

THE EFFECT OF SOCIAL COHESION ON DIARRHEAL DISEASE OVER TIME IN RURAL ECUADOR

Sonia T. Hegde[1], Bhramar Mukherjee[1], James Trostle[2], Joseph Eisenberg[1]

[1]University of Michigan, Ann Arbor, MI, United States, [2]Trinity College, Hartford, CT, United States

Though social organization and connectedness are critical to the functioning of communities and disease reduction because of behavior change, infectious disease transmission studies typically use social networks as maps of direct contact to model risk. Prior cross-sectional analyses in Ecuador have suggested a greater density of social ties between individuals in remote communities may lead to the spread of sanitation practices, both individual and collective, that help reduce the transmission of diarrheal disease. With social network data from 2007-2013 collected from the same cohort of villages in Ecuador, we evaluate the association between social cohesion and acute gastrointestinal illness (AGI) over time. Using different measures of social cohesion: individual trust in a community, individual belongingness to community social organizations, and social network structure, we examine the effect of social cohesion on AGI in 20 communities among persons >13 years of age. We determine social network structure from two different types of networks: who an individual passes time with and who an individual goes to for important matters. From 2007-2013, there is an 18% increase in AGI (10.6%-12.5%), a 36% reduction in trust, and a 44% reduction in the number of social organizations an individual belongs to. Using a Bayesian hierarchical model with an informative prior, we find an individual's trust in her community becomes more protective against AGI over time (2013: OR 0.64(0.54,0.75)). Individuals who are socially deviant, have a greater number of ties than community average, have increased risk of AGI over time in a passing time network (2007: OR 0.71 (0.66,0.77); 2013: OR 1.20 (1.11,1.30)). On the other hand, individuals who live in communities with a greater average of ties in an important matters network become more protected against AGI over time (2007: OR 0.89 (0.74,1.06); 2013: OR 0.74 (0.63,0.87)). Measures of social cohesion from different network structures, passing time and important matters, exhibit opposing effects on AGI. Understanding social dynamics in communities could improve approaches to intervention implementation.

1367

TEMPERATURE AND ALL-CAUSE DIARRHEA IN NORTHERN ECUADOR: CHANGING SEASONALITY AFTER ROTAVIRUS VACCINE INTRODUCTION

Alicia N. Kraay[1], Edward L. Ionides[1], Karen Levy[2], Morgan C. Levy[3], Joseph N. Eisenberg[1]

[1]University of Michigan-Ann Arbor, Ann Arbor, MI, United States, [2]Emory University, Atlanta, GA, United States, [3]University of California-Berkeley, Berkeley, CA, United States

In general, diarrhea is more prevalent in warmer seasons. However, this effect varies by pathogen—warm temperatures are generally associated with bacterial diarrhea whereas rotavirus diarrhea is more common in cooler seasons. In this analysis, we assess the relationship between temperature and all-cause diarrhea in rural northwestern coastal Ecuadorian communities in two different surveillance periods: 2003-2007 and 2011-2013. We examine whether the introduction of rotavirus vaccination late in 2008, between the two periods, modifies the overall seasonality of diarrhea. We use generalized Poisson regression models with an offset for population size to estimate the effect of temperature on all-cause diarrhea separately for the two surveillance periods. We account for community clustering using an auto-regressive correlation structure and ran these analyses stratified by age group (<5 and >5 years) and for both age groups combined. While the two surveillance periods had similar overall rates of diarrhea, higher vaccine coverage was associated with lower rates of diarrhea (IRR=0.304, 95% CI: 0.118, 0.785). This association was present for all age groups, including among older, unvaccinated children and adults. In the pre-vaccine period, diarrhea outbreaks were more common during the cooler weather months, with incidence peaking in September-November. Transient drops in temperature one week prior were associated with increased diarrhea among young children (<5 years) (IRR=0.770, 95% CI: 0.612, 0.968), but not adults, consistent with viral diarrhea. Seasonality was similar in the post-vaccine compared to the pre-vaccine period, but the overall peak was earlier (July-September) and the transient drops in temperature were attenuated (IRR=0.866, 95% CI: 0.621, 1.21). The effect of temperature was not modified by vaccine coverage, community hygiene score, coverage of improved sanitation, or remoteness. These analyses are suggestive that diarrhea has been associated with cooler temperatures in Ecuador but that this tendency may be shifting due to the introduction of rotavirus vaccination.

1368

EFFECT OF DRINKING WATER CHLORINATION AT THE POINT-OF-COLLECTION ON CHILD DIARRHEA IN DHAKA, BANGLADESH: A DOUBLE-BLIND CLUSTER-RANDOMIZED CONTROLLED TRIAL

Amy J. Pickering[1], Sonia Sultana[2], Yoshika Crider[3], Syed Anjerul Islam[2], Frederick Goddard[4], Jenna Swarthout[1], Shreyan Sen[5], Raga Ayyagari[5], Stephen Luby[5]

[1]Tufts University, Medford, MA, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]University of California Berkeley, Berkeley, CA, United States, [4]Emory University, Atlanta, GA, United States, [5]Stanford University, Stanford, CA, United States

In cities of low-income countries, few utilities are able to maintain fully pressurized piped systems that deliver water 24 hours a day, resulting in contaminated water at the point-of-collection. We evaluated the effect of a decentralized, point-of-collection water chlorination intervention on child health through a double-blind cluster-randomized controlled trial among 100 shared water points in Dhaka, Bangladesh. The treatment group received drinking water automatically chlorinated by a solid tablet chlorine doser, while the control group received water treated by a doser identical in appearance that supplied vitamin C. Drinking water at treatment taps had detectable chlorine residual 81% of the time (compared to 0% at control taps). The mean total chlorine residual at taps in the treatment group was 0.4 ppm, which is above international minimum guidelines but below the average dose of typical point-of-use chlorine treatment products. When asked to guess their treatment status, 30% of respondents in the treatment group and 20% in the control group thought the device was dosing chlorine. Children in the treatment group had 23% less caregiver reported diarrhea than children in the control group (Treatment: 10%, Control: 7.5%; PR: 0.77, 95% CI 0.65-0.91; N=4227). Reported illness-related expenditures and antibiotic consumption in the past two months per child were significantly lower in the treatment group than the control group. There were no significant differences between groups in weight-for-age z-scores or negative control outcomes (e.g. bruising). Whereas many previous water intervention trials have focused on household-level water treatment, our findings demonstrated effectiveness of an automatic point-of-collection water

treatment intervention. While previous water treatment blinded trials have failed to detect health impacts, we estimated a significant reduction in child diarrhea in a low-income urban setting. Our results also suggest targeting a low chlorine residual dose (0.3-0.5ppm) in an effort to increase acceptability of chlorinated water can still improve water quality and reduce the risk of diarrhea.

1369

PERCEPTIONS, EXPERIENCES AND ACCEPTABILITY OF A WATER INTERVENTION USING RIVERBANK FILTRATION TECHNOLOGY IN RURAL INDIA

Sarah L. McGuinness[1], Joanne O'Toole[1], Asha Giriyan[2], Chetan A. Gaonkar[2], Veerabaswant Reddy[2], Kavita Patil[2], Fraddry D'Souza[2], Ramkrishna Vhaval[2], Darshini R. Ayton[1], Karin Leder[1]

[1]Monash University, Melbourne, Australia, [2]The Energy and Resources Institute (TERI), Western Regional Centre, Goa, India

Universal and equitable access to safe and affordable drinking water is one of the United Nations' Sustainable Development Goals. While global gains towards this goal have been made, many communities are unable to afford technical water treatment solutions. Riverbank filtration technology (RBF) is an inexpensive water treatment technique that can be delivered at a community level and sustained using local resources. In the setting of a stepped-wedge cluster randomised controlled trial of a water intervention in rural Karnataka, India, we performed a mixed methods study to evaluate the perceptions, experiences and acceptability of RBF-treated water delivered to community village tanks. Quantitative data was collected through household surveys and analysed using Stata version 14. Qualitative data were collected through semi-structured household-level interviews and focus groups with data collectors. All discussions were audio-recorded, transcribed and translated verbatim prior to thematic analysis using NVivo version 11. Uptake of RBF water supply was not universal; at the conclusion of the study, less than 20% of households described it as their primary source of drinking water. Qualitative analysis revealed reluctance among many villagers to adopt a new primary drinking water source due to the belief that changes in water source would result in diarrhoea and other symptoms. Other barriers to uptake included salinity and hardness of the water, which affected taste, cooking time and its ability to form a lather with soap when washing clothes. The storage of RBF water in plastic tanks was perceived to affect the quality and taste of the water, and many householders expressed that their preference would be to have water piped directly to their homes. While RBF has potential as a sustainable drinking water solution for some rural communities in India, we identified significant barriers to its uptake and use, including its mode of delivery. The design and delivery of future RBF interventions should ensure that community consultation and education are built into the intervention delivery.

ADAPTIVE SITES ALLOCATION FOR TYPHOID ENVIRONMENTAL SURVEILLANCE IN TWO INDIAN CITIES

Yuke Wang, Ashutosh Wadhwa, Wolfgang Mairinger, Christine Moe

Emory University, Atlanta, GA, United States

Environmental surveillance (ES) detects circulation of pathogens in the environment and has been used to complement clinical surveillance to monitor disease (e.g. poliovirus) transmission in communities. Although WHO published guidelines for ES for poliovirus in 2003, a systematic method to determine the locations of ES sites does not exist. Our goal is to choose ES sites for typhoid to achieve high sensitivity in two Indian cities. We developed an adaptive ES sites allocation method that dynamically updates sites based on their performance. In the pilot phase, 30 sewage samples from different areas of Kolkata were analyzed for *E. coli*, human-specific phage, *Salmonella* Typhi and *Salmonella* Paratyphi A to determine an initial range of detection frequency and concentration for each target microorganisms. Presences of *S*. Typhi and *S*. Paratyphi A in specific geospatial areas and the sensitivities of different potential ES sites were simulated. A certain number of ES sites were initialized (selected from potential ES sites) based on prior information/randomization and periodically updated based on their performance. The sensitivity of a site (how often it can detect fecal contamination, human fecal contamination, and *S*. Typhi or *S*. Paratyphi A) and "information loss" by removing a site will be periodically evaluated to determine which site(s) should be relocated. Parameters and settings (the number of sites initialized, the number of sites relocated per update, the time between two updates etc.) for the site initialization and update process can be optimized to rapidly achieve an ES system with high sensitivity. 72 scenarios have been tested. With appropriate parameters and settings, a high average sensitivity of sites (80%) were reached within 10 updates (12 weeks per update) from randomized initial sites (average sensitivity around 50%). This study also examined how the adaptive site allocation method performs for spatially-correlated sites, seasonality of *S*. Typhi and *S*. Paratyphi A circulation, and temporal changes in high-risk areas. In those scenarios, the adaptive sites allocation method consistently outperformed the fixed sites.

1371

INVESTIGATING IMMUNE SIGNATURES IN MALARIA-EXPOSED CHILDREN

Yaw Bediako[1], Rhys Adams[1], Adam Reid[2], John J. Valletta[3], Francis M. Ndungu[4], Jedidah Mwacharo[4], Joyce M. Ngoi[4], Domtila Kimani[4], Oscar Kai[4], Juliana Wambua[4], George Nyangweso[4], Etienne P. de Villiers[4], Mandy Sanders[2], Magda E. [1]The Francis Crick Institute, London, United Kingdom, [2]Wellcome Trust Sanger Institute, Hinxton, United Kingdom, [3]University of Exeter, Exeter, United Kingdom, [4]KEMRI-Wellcome Trust Research Program, Kilifi, Kenya, [5]Weatherall Institute of molecular medicine, University of Oxford, Oxford, United Kingdom, [6]Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom

While naturally acquired immunity to Malaria provides promise of developing an effective vaccine, decades of study have yielded no definitive correlates of protection and the most advanced vaccine candidate provides only partial and short-lived protection. Given the complicated host-pathogen interactions involved it is unlikely that approaches focused on few parameters will unravel the underlying immune mechanisms responsible for immunity. We used a systems approach comprising whole blood transcriptomic, cellular and plasma analyses on a cohort of children who had been under active surveillance for malaria for several years. We developed and verified systems immunology tools capable of identifying molecular and cellular signatures of children of similar age who have experienced a "high" or "low" number of clinical malaria episodes. Transcriptomic, cellular, cytokine and active malaria surveillance were integrated to define signatures associated with malaria experience. High-episode children are distinguishable from low-episode children by enhanced expression of genes involved in immune activation and regulation, with modular analysis revealing enrichment in interferon-inducible genes. For a subset of high-episode children we also note a distinct signature related to hemoglobin biosynthesis, which appears to correlate with clinical anaemia, and may reflect enhanced erythropoiesis in response to malaria-induced anaemia. The transcriptomic signature of enhanced immune activation in high-episode children is supported by elevated levels of pro-inflammatory cytokines (including IL-6 and TNF-α), while high IL-10 and a subset of $\gamma\delta$ T cells distinguished high- from low- episode children. Through cellular deconvolution of the transcriptomic data, high-episode children appear to be associated with functionally altered B cells, $CD8^+$ T cells and neutrophils compared to low-episode children. Whole blood analysis reveals a distinct immune signature

associated with repeated episodes of clinical malaria. The implications of this signature for anti-malarial immunity are the focus of an on-going project.

1372

B CELL MEDIATED AUTOIMMUNE ANEMIA IN MALARIA PATIENTS

Juan Rivera-Correa[1], Maria Mackroth[2], Thomas Jacobs[2], Julian Schulze zur Wiesch[3], Thierry Rolling[2], Ana Rodriguez[1]

[1]New York University School of Medicine, New York, NY, United States, [2]Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, [3]University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Malaria is still one of the leading infectious diseases in the world and a global health burden. Severe anemia is one of the most common malaria-associated complications, which accounts to both increased morbidity and mortality. Our lab has recently identified autoantibodies that target the membrane lipid phosphatidylserine (PS) on uninfected erythrocytes as a major promoter of malarial anemia in a rodent model. High levels of anti-PS antibodies also correlate with *P. falciparum* malarial anemia in patients. Additionally, we have recently characterized an atypical population of B-cells expressing the transcription factor T-bet and surface marker CD11c as being major producers of anti-PS IgG antibodies during malarial anemia in a mouse model and in *ex-vivo* cultures of naïve human PBMCs exposed to *P. falciparum* infected erythrocyte lysates. The aim of this work was to identify the presence of T-bet$^+$ B-cells and its possible correlation with anti-PS IgG antibodies and anemia in malaria patients. To test this hypothesis, we assessed PBMCs from German *P. falciparum* malaria patients for different B cell populations such as Plasma cells, Naïve, Immature, Activated memory, Classical memory, Atypical memory, CD11c$^+$ and T-bet$^+$ B-cells. Furthermore, we assessed the plasma of these patients for anti-PS and anti-red blood cell (RBC) lysate IgG antibodies, hemoglobin as a measurement of anemia, along with other clinical parameters such RBC and thrombocyte counts. Our results showed an inverse correlation between percentage of T-bet$^+$ B-cells and hemoglobin hence associating these B-cells with anemia development in this cohort of malaria patients. Moreover, we also observed that Atypical Memory B-cells (CD21$^-$, CD27$^-$, CD20$^+$ CD10$^-$), along with Fcrl5$^+$ B-cells, that are characteristic of malaria patients and also express T-bet, correlate with anemia development. Lastly, we observed CD11c$^+$ B-cells correlating positively with plasma anti-RBC antibody levels and a positive trend with anti-PS antibody levels. These results suggest that T-bet B cells may contribute to anemia in malaria patients through the generation of autoimmune antibodies.

EX VIVO ANALYSIS OF *PLASMODIUM FALCIPARUM*-SPECIFIC B CELL RESPONSES TO NATURAL MALARIA INFECTION IN CHILDREN AND ADULTS

Christine S. Hopp[1], Sarah Andrews[2], Michael Chambers[2], David J. Leggat[2], Silvia Portugal[3], Ogobara K. Doumbo[4], Boubacar Traore[4], Adrian B. McDermott[2], Susan K. Pierce[1], Peter D. Crompton[1]

[1]Laboratory of Immunogenetics, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States, [2]Immunology Core Section, VRC/National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [3]Centre for Infectious Diseases, Parasitology, Heidelberg University Hospital, Heidelberg, Germany, [4]Malaria Research and Training Centre, Department of Epidemiology of Parasitic Diseases, International Center of Excellence in Research, University of Sciences, Technique and Technology of Bamako, Bamako, Mali

In naturally acquired immunity to malaria, antibodies that reliably protect are only acquired after years of repeated *Plasmodium falciparum* (*Pf*) infections. We have shown in Mali that this inefficiency in humoral immunity to malaria is associated with a large expansion of CD21^{lo}CD27$^-$ 'atypical' MBCs. The function of atypical MBCs remains elusive, as they exhibit altered B cell receptor (BCR) signaling and when activated fail to secrete cytokines and antibodies. We set out to study whether atypical or classical B cells are recruited into the immune response to a febrile malaria infection: using *Pf* antigen probes, we characterized *Pf*AMA1/*Pf*MSP1-specific B cells in Malian children and adults (ages 2 to 36 years), at well-defined time points before, during and after a febrile malaria episode. Our preliminary analysis shows that *Pf*-specific atypical MBCs display signs of activation after a febrile malaria infection. Using antigen probes to track influenza hemagglutinin-specific B cells in the same individuals, we have gained insight into the relative role of *Pf* in driving atypical MBC expansion and have also compared the magnitude and kinetics of *Pf*- and influenza-specific atypical and classical MBC responses. We further show that classical *Pf*-specific IgG$^+$ MBCs are activated and expanded, but interestingly, that the majority of activated *Pf*-specific MBCs are unswitched, expressing surface IgM. Additionally, we have single cell sorted *Pf*- and influenza-specific MBCs to compare their BCR features (VH gene diversity and somatic hypermutation rates). This analysis provides important new insights into the mechanisms underlying the inefficient acquisition of naturally acquired immunity to malaria in children.

1374

PREDOMINANT LOSS OF LOW AVIDITY IGG ANTIMALARIAL ANTIBODIES ASSOCIATED WITH REDUCTION IN INFECTION AFTER INDOOR RESIDUAL SPRAYING IN NAGONGERA, UGANDA

Isaac Ssewanyana[1], John Rek[1], Isabel Rodriguez[2], Lindsey Wu[3], Emmanuel Arinaitwe[1], Joaniter Nankabirwa[1], Harriet Mayanja-Kizza[1], Philip J. Rosenthal[2], Grant Dorsey[2], Moses Kamya[1], Chris Drakeley[3], Bryan Greenhouse[2], Kevin Tetteh[3]

[1]Infectious Diseases Research Collaboration (IDRC), Kampala, Uganda, [2]University of California San Francisco (UCSF), San Francisco, CA, United States, [3]London School of Hygiene & Tropical Medicine (LSHTM), London, United Kingdom

Immunity to *Plasmodium falciparum* (*Pf*) malaria is acquired slowly after repeated exposure and poorly maintained, with antibodies playing a critical role. We evaluated total and high avidity IgG antibodies to *Pf* blood stage antigens in 160 participants from Nagongera, Uganda, where childhood malaria incidence declined from 4 episodes per person per year to near zero following indoor residual spraying of insecticide (IRS). Samples were obtained at 4 time points, from a longitudinal cohort with all episodes of *Pf* infection and malaria recorded: 12 and 6 months before IRS and 6 and 12 months post IRS. IgG antibodies against 19 antigens were measured using a multiplex bead array (MagPix platform). Levels of high avidity (strongly binding) IgG antibodies were measured by adding guanidine hydrochloride (GuHCl) to dissociate weakly binding antibodies. The avidity index (AI) was calculated as median fluorescence intensity (MFI) of GuHCl treated samples (avid) divided by MFI of untreated samples (total). We observed preferential net loss of of total vs. avid antibody for all antigens (e.g. Rh4.2; median 1.04 vs 0.32 log MFI, SBP1; 0.91 vs 0.21, HSP40; 0.74 vs 0.15, Hpy2; 0.74 vs 0.08, EBA140; 1.02 vs 0.47) between 6 months pre (highest incidence) and 12 months post IRS (lowest incidence). Including all 4 time points in a generalized estimation equation model, net loss of both total and avid antibodies was significantly associated with days since last infection in all antigens, independent of age. Preferential persistence of avid antibodies post infection manifested into net increased median AI for 17/19 antigens (e.g. SBP1; 0.25, HSP40; 0.17, Hpy2; 0.16, EBA140; 0.12). Our results suggest that frequent infection with *Pf* results in the acquisition of IgG antibodies with predominantly low avidity, but that low avidity antibodies wane more rapidly than high avidity antibodies following a reduction in exposure. We postulate that high avidity antibody pool is from affinity matured long lived plasma cells. This pool may be responsible for maintenance of circulating antibody levels in absence of infection and may play a role in maintenance of acquired immunity.

1375

FUNCTIONAL ANTIBODIES AGAINST *PLASMODIUM FALCIPARUM* SPOROZOITES ARE ASSOCIATED WITH A LONGER TIME TO NATURALLY ACQUIRED PCR-DETECTED INFECTIONS AMONG SCHOOLCHILDREN IN BURKINA FASO

Aissata Barry[1], Marije Behet[2], Bronner Goncalves[3], Koen Dechering[2], Moussa W. Guelbeogo[1], Alphonse Ouedraogo[1], Issiaka Soulama[1], Issa Nébié Ouedraogo[1], Amidou Diarra[1], Emilie Badoum[1], Mireille Ouedraogo[1], Désiré Kargougou[1], Zongo Zoumanaba[1], Judith Bolscher[4], Chris Drakeley[3], Alfred B. Individuals living in malaria-endemic regions can develop naturally acquired immunity against malaria severe disease and death, but it is unclear if sterilizing immunity does develop even after years of exposure. This was addressed in a longitudinal study of schoolchildren in Burkina Faso. Healthy schoolchildren (parasite-free by microscopy) received a curative dose of antimalarial to clear possible sub-patent infections before the start of the transmission season. Subsequently, *P. falciparum* infections were detected by PCR during weekly visits. Upon parasite detection, children were followed daily basis until day 7 then weekly basis up to 35 days. Participants were closely monitored for the development of malaria symptoms. Anti-malarial was given upon the detection of symptoms or 35 days after parasite detection, whichever came first. Venous blood sample were collected at enrolment for immunological assessments. Antibodies to circumsporozoite protein (CSP) were detected by ELISA. Sporozoite gliding inhibition of purified IgG was assessed using NF54 sporozoites; hepatocyte invasion using primary hepatocytes. 51 infections were monitored; the median time to first detection of infection by PCR was 27 days. Although antibodies responses to pre-erythrocytic antigens were low, IgG of the majority of schoolchildren reduced *in vitro* sporozoite gliding motility with a median gliding inhibition of 59.6%. Gliding inhibition and antisporozoites antibodies levels were strongly correlated ($P<0.0001$). Also, there was a positive correlation between gliding inhibition and reductions in hepatocyte invasion ($P=0.02$). Survival analysis indicated a longer time to infection detection in individuals displaying strong gliding inhibition. Naturally exposed children with functional anti-sporozoite antibody responses have an increased time to developed *P. falciparum* infection compared to children with lower responses. This response does not prevent them from becoming infected during the season but is important for the development and evaluation of interventions that aim to prevent malaria infections by active or passive immunisation.

IGG3 SUBCLASS ANTIBODIES MEDIATE THE MOST EFFECTIVE FUNCTIONAL RESPONSES AGAINST *PLASMODIUM FALCIPARUM* MEROZOITE INVASION LIGANDS

Vashti Irani[1], Peck Szee Tan[2], Andrew J. Guy[1], Dean W. Andrew[1], Damien Drew[1], Gaoqian Feng[1], Linda Reilling[1], Kathirvel Alagesan[3], Daniel Kolarich[3], Mirielle H. Lahoud[2], James G. Beeson[1], Paul A. Ramsland[4], Jack S. Richards[1]

Naturally-acquired antibodies are important for protection from symptomatic malaria. Some antibodies target merozoites and inhibit erythrocyte invasion. Field studies suggest that these antibody responses are typically skewed to IgG1 or IgG3 subclasses, and that IgG3 responses often have a stronger association with protection. However, it is unclear how their different properties impact protective immunity, and therefore which IgG subclass is required for the most effective vaccine response. We hypothesised that the different effector responses of these IgG subclasses would impact functional immunity. To assess this, we made IgG subclass-switch antibodies; these are mAbs engineered with the same variable region, i.e. same epitope target, but different human IgG subclass backbones, and then compared them using *in vitro* functional assays. We focused on merozoite antigens EBA-175, Rh5 and AMA-1, as they are important invasion ligands and leading vaccine candidates. For each antigen, existing monoclonal antibodies (mAbs) that target known neutralising epitopes were selected, and used to express IgG subclass-switch mAbs. Characterisation confirmed their expected size, subclass, similar N-glycosylation patterns and ability to bind their respective recombinant and native proteins. Unexpectedly, IgG3 variants showed significantly greater inhibition of merozoite invasion compared to other IgG subclasses. IgG3 variants were most effective at C1q fixation and subsequent deposition of the membrane attack complex. These results indicate the key role of IgG3 in mediating functional immunity and support findings from field studies that show strong associations between IgG3 responses and protection. It is likely that the superior Fab flexibility of IgG3 enables more effective antigen binding leading to enhanced neutralisation and formation of IgG complexes for complement fixation. These findings provide a strong rationale to explore the development and efficacy of vaccines that induce strong IgG3 responses.

Cerebral malaria (CM) is one of the most lethal complications of *Plasmodium falciparum* infection, responsible for a large fraction of the nearly 500,000 malaria-related deaths annually. In the experimental mouse model of CM (ECM), mice are inoculated with red blood cells infected with *Plasmodium berghei* ANKA (PbA) parasites and develop a CM-like disease within 6-10 days post-infection (dpi). We found that treatment of C57BL/6 mice with interleukin (IL)-15 complexes (IL-15C; IL-15 bound to an IL-15Rα-Fc fusion protein) prevented the development of PbA-induced ECM. IL-15C-expanded natural killer (NK) cells were necessary and sufficient for protection against ECM. IL-15C treatment also decreased CD8+ T cell activation in the brain and prevented blood brain barrier breakdown without influencing parasite load. Moreover, we found that IL-15C treatment of mice induces IL-10 expression in NK cells, and that IL-10 is required for IL-15C-mediated protection from ECM. Additionally, primary human NK cells produce IL-10 following *in vitro* culture with IL-15 or with ALT-803, a modified human IL-15C. Finally, we show that ALT-803 mediates similar induction of IL-10 in mouse NK cells and protection against ECM. Using conditional genetic deletion strategies, we are investigating the cellular target(s) of NK cell-derived IL-10, including CD8+ T cells, endothelial cells, and myeloid cells. We are also investigating the signaling pathway required for IL-15C-mediated induction of IL-10 in NK cells. In summary, these data indicate that NK cells – which are typically involved in promoting inflammatory responses – can also restrain damaging immune responses, suggesting that IL-15C holds promise as an adjunctive therapy for immune-mediated diseases, potentially including CM.

EVALUATION OF THE PHARMACOKINETIC-PHARMACODYNAMIC RELATIONSHIP OF PRAZIQUANTEL IN THE *SCHISTOSOMA MANSONI* MOUSE MODEL

Nada Abla[1], Jennifer Keiser[2], Natalie Reimers[3], Mireille Vargas[2], Helmut Haas[3], **Thomas Spangenberg**[4]

[1]MMV, Geneva, Switzerland, [2]STPH / University of Basel, Basel, Switzerland, [3]Helminguard, Borstel, Germany, [4]Merck (EMD) Serono, Coinsins, Switzerland

After more than 40 years of use, Praziquantel (PZQ) still remains the drug of choice for the treatment of intestinal and urogenital schistosomiasis. Its anti-parasitic activity resides primarily in the (*R*)-enantiomer. Hitherto neither the molecular target nor the pharmacokinetic-pharmacodynamic relationship have been fully elucidated. Here we investigated the efficacy and pharmacokinetics of PZQ in the *Schistosoma mansoni* mouse model to determine the key factors that drive its efficacy. Dose-response studies with racemic PZQ with or without addition of an irreversible pan-cytochrome P450 (CYP) inhibitor, 1-aminobenzotriazole (ABT), were performed. In addition, efficacy of PZQ in the presence of the CYP inducer, dexamethasone (DEX), was determined. Plasma samples were obtained by tail vein bleeding at 4 time points. The (*R*)-PZQ levels were determined using a LC-MS/MS method. Non-compartmental pharmacokinetic analysis was performed using PKsolver. In addition, experiments using an enhanced *in vitro* assay were conducted. We found that the use of ABT increased (*R*)-PZQ plasma exposures in the systemic circulation by ~10 to 20 fold but the latter were not predictive of efficacy. The use of DEX decreased plasma exposures of (*R*)-PZQ in the systemic circulation by ~10 fold without reducing efficacy. We extrapolated the (*R*)-PZQ concentrations in mouse portal vein / mesenteric veins from the systemic exposures and found that a free exposure of (*R*)-PZQ of ~ 20 µM*h in the portal vein was needed to obtain a worm burden reduction >60%. It is suggested that the high (*R*)-PZQ concentrations available before the hepatic first pass metabolism drive the efficacy against *S. mansoni* adult worms residing in the mesenteric veins. It is then possible that the current dosing regimen of 40 mg/kg in preventive chemotherapy programs may provide suboptimal concentrations in low-weight patients such as children, due to smaller total amounts of drug administered, and may consequently result in lower cure rates.

1379

SAFETY AND EFFICACY OF NEW ORAL DISPERSIBLE TABLET (ODT) FORMULATIONS OF RACEMATE- AND L-PRAZIQUANTEL IN 2 TO 6 YEARS OLD CHILDREN INFECTED WITH SCHISTOSOMIASIS

Elly Kourany-Lefoll[1], Eliézer K. N'Goran[2], NAD. Aka[2], Mamadou Ouattara[2], Aliona Tappert[3], Oezkan Yalkinoglu[3], Brooke Hayward[4], Eric Huber[5], Deon Bezuidenhout[6], Wilhelmina Bagchus[7]

[1]Ares Trading S.A., Switzerland, an affiliate of Merck KGaA, Darmstadt, Germany, [2]Université Félix Houphouët-Boigny, Abidjan, Côte D'Ivoire, [3]Merck KGaA, Darmstadt, Germany, [4]EMD Serono, Inc., Rockland, MA, United States, [5]Swiss Tropical and Public Health Institute / University of Basel, Basel, Switzerland, [6]Merck (Pty) Ltd, South Africa, an affiliate of Merck KGaA, Darmstadt, Germany, [7]Merck Institute of Pharmacometrics, Lausanne, Switzerland, an affiliate of Merck KGaA, Darmstadt, Germany

The Pediatric Praziquantel Consortium is developing a praziquantel (PZQ) orally dispersible tablet (ODT) 150 mg that is suitable and palatable for children ≤6 years infected with schistosomiasis. Two candidate ODTs are currently being tested: one containing the L-PZQ enantiopure active pharmaceutical ingredient and an ODT containing the racemate PZQ molecule. Results of an open label, dose-finding phase II trial in children 2 to 6 years infected with *Schistosoma mansoni* in Côte d'Ivoire (ClinicalTrials.gov Identifier: NCT02806232) will be presented. A total of 420 children, 60 in each of 7 cohorts, were randomized to receive 3x20 mg/kg or a single dose of 40 mg/kg of Biltricide®, 40 mg/kg or 60 mg/kg of racemate-PZQ ODT, or 30 mg/kg, 45 mg/kg or 60 mg/kg of L-PZQ ODT. Cure rate (CR) 14 to 21 days post-treatment was the primary efficacy endpoint; egg reduction rate (ERR) and rate of related treatment-emergent adverse events (TEAEs) were secondary endpoints. CRs and ERRs were assessed using triplicate Kato-Katz on 2 faecal samples collected within 5 consecutive days. CRs for participants with follow-up Kato-Katz results and no clinically important protocol deviations (n=372) were >80% for all cohorts. L-PZQ 60 mg/kg and 45 mg/kg showed the highest efficacy among ODTs: CR= 89.3% (95% confidence interval [CI]: 78.1%, 96.0%) and CR= 88.0% (95% CI: 75.7%, 95.5%), respectively. ERRs were ≥90% for all cohorts. Somewhat lower CRs were observed in moderate/heavy *versus* light infected patients for all cohorts. No differences in CR were observed for males versus females or for 4- to 6-year-old children versus younger participants. CRs diagnosed using the Point-of-Care Circulating Cathodic Antigen test were consistent with the Kato Katz results but lower for all cohorts. Only 64 subjects (15.2% of 420 treated) had 68 related TEAEs, of which most were mild and transient, and resolved within 24 hours. Both ODT formulations were well tolerated at all doses tested.

Human schistosomiasis is a debilitating, life-threatening disease affecting more than 250 million people in as many as 78 countries. Schistosomiasis is a neglected tropical disease and is second only to malaria as "the most devastating parasitic disease". There is only one drug of choice effective against all three major species of *Schistosoma*, Praziquantel (PZQ). However, as with many monotherapies, resistance is emerging in the field and can be selected for in the laboratory. Previously used therapies include Oxamniquine (OXA), however shortcomings such as toxicity and affordability resulted in discontinuation. Our collaborations with medicinal chemists and structural biologists have enabled us to develop and test novel drug derivatives of OXA to treat this disease. Using an iterative process for drug development, we have successfully identified one derivative that is effective against all three species of the parasite at varying levels and shows promising preliminary *in vivo* efficacy, CIDD-0066790. As CIDD-0066790 is a racemic mixture, we have isolated the R and S enantiomers of this derivative and identified the R form as most effective. Furthermore, we have identified three more efficacious derivatives, one of which CIDD-0072398 kills 100% of *S. mansoni* worms. We will present data on the *in vitro* and *in vivo* efficacy of these 3 novel drugs. Our goal is to generate a secondary therapeutic that can be used in conjunction with Praziquantel to overcome the ever-growing threat of resistance. In this regard we are testing our best derivatives in conjunction with PZQ to determine efficacy of combination therapy. The ability and need to design, screen, and develop future, affordable therapeutics to treat human schistosomiasis is critical for successful control program outcomes.

1381

SCHISTOSOMA MANSONI EGGS, ANTIGENS AND DNA CLEARANCE CURVES AFTER PRAZIQUANTEL TREATMENT AND REINFECTION RATES OVER SIX MONTHS: DIFFERENTIATING BETWEEN RAPID REINFECTION AND DRUG RESISTANCE

Andrina Nankasi[1], Moses Arinaitwe[1], Christina L. Faust[2], Fred Besigye[1], Diana Ajambo[1], Lauren V. Carruthers[2], Moses Adriko[1], Govert J. van Dam[3], Lisette van Lieshout[3], Paul L. Corstjens[3], Paul L. Corstjens[3], Edridah M. Tukahebwa[1], **Poppy H L Lamberton**[2]

Schistosoma mansoni causes the debilitating disease schistosomiasis. The World Health Organization recommends using Kato-Katz to detect eggs in stool and infection prevalences guide mass treatment decisions. However, Kato-Katz has low sensitivity, particularly with low intensities and/or post treatment. Rapid circulating cathodic antigen tests (POC-CCA) are more sensitive and WHO interim guidelines have been published for their use in disease mapping. While there are several methods for schistosomiasis diagnosis, including DNA analyses in blood and stool, it remains unclear which are best for monitoring drug efficacy in different endemic settings. Guidelines recommend using Kato-Katz 2 to 4 weeks post treatment. However, previous data have shown large discrepancies between cure rates measured by Kato-Katz and POC-CCA. Low egg counts, but high POC-CCA results post treatment could be due to juvenile worms tolerant to praziquantel and rapid reinfection, or due to worm surviving treatment (resistance) but with reduced egg production (embryostasis). Embryostasis would be undetected by Kato-Katz, and POC-CCAs cannot differentiate it from reinfection. There is a need to optimize drug-efficacy protocols and timeframes to capture true cure rates (adult worms dying) and differentiate reinfection from resistant worm embryostasis to inform control interventions. We present data from 55 children over six months following praziquantel treatment: characterizing parasite egg, antigen and DNA levels twice a week in stool, urine, and blood to elucidate parasite clearance and reinfection in a high endemic setting. Using sibship techniques, we identified full- and half-siblings through time, inferring if antigens are caused by worms surviving treatment or maturing juveniles. These data provide novel information on worm clearance, effective breeding populations, density-dependent egg production, fecundity compensation and embryostasis following treatment within individual children. Findings will inform optimal protocols and timelines for monitoring clearance and reinfection in high endemic settings.

1382

OVERCOMING CHALLENGES IN THE DIAGNOSIS OF *SCHISTOSOMA MANSONI* INFECTIONS USING POINT OF CARE METHODS, RECOMBINANT PROTEIN AND MONOCLONAL ANTIBODY TECHNOLOGIES

Rafaella F. Queiroz[1], Paulo Marcos Z. Coelho[1], Donald A. Harn[2]

[1]Oswaldo Cruz Foundation, Belo Horizonte, Brazil, [2]University of Georgia, Athens, GA, United States

Control constraints of Schistosomiasis include the lack of diagnostic methods with high sensitivity. We develop a prospective study in southeast Brazil to standardize new sensitive and rapid diagnostic methods for *Schistosoma mansoni* infection. Currently, we are investigating 6 endemic areas (>1000 individuals with chronic infection) and 84 travelers infected in a freshwater pool (with acute infection). Sera, urine, feces and saliva samples were used for the standardization/validation of innovative methods, including acute, chronic and post-treatment patients. Comparisons are performed with eggs in feces by 24 Kato-Katz slides and 2 analyses of Saline Gradient and clinical symptoms. Within our new point-of-care methods, we use selected recombinant proteins (MEAr, CCAr) and their respective monoclonal antibodies. We were able to detect the disease early as 10 days post-infection and more than 95% of positive cases from chronic low endemicity areas with our Dot Blot, IMS and Fluo-IMS rapid and cheap methods. Plus, POC FLT immunochromatography method uses concentrated urine to increase POC-CCA® sensitivity from 6% to 56% with a accuracy of 0.9, being equivalent to 21 Kato-Katz slides. Monoclonal antibody and recombinant protein technologies allowed a superior detection method when comparing to the conventional methods. In conclusion, data showed 100% of sensitivity of chronic patients and 98% of acute patients with new improvements and innovative POC methods.

1383

URINE POC-CCA STRIP ASSAY: A QUANTITATIVE METHOD FOR DIAGNOSING INTESTINAL SCHISTOSOMIASIS?

Miriam Casacuberta Partal[1], Thomas F. Scherr[2], Pytsje T. Hoekstra[1], Lisette van Lieshout[1], Govert J. van Dam[1]

[1]Leiden University Medical Center, Leiden, Netherlands, [2]Vanderbilt University, Nashville, TN, United States

In intestinal schistosomiasis light intensity infections are difficult to detect in the field, especially in endemic regions when using non-sensitive methods like the Kato-Katz technique. The point-of-care strip assay for the detection of the schistosome Circulating Cathodic Antigen (POC-CCA) in urine has shown to be a user-friendly and more sensitive alternative for the diagnosis of *Schistosoma mansoni* infections, but the reading is observer dependent and is often interpreted in a qualitative way. Therefore, in particular when the infection burden is low and the test lines become less strong, misinterpretation of the trace test lines might lead to a different result interpretation. The current study evaluates different approaches for quantification of the POC-CCA readings in the field and a standardized set-up for the strip readings with a focus on the low intensity signals. The innovative approach uses 3 different techniques to read the cassettes: (1) using a portable Qiagen ESEQuant Lateral Flow Reader; (2) performing visual readings compared against a series of artificial cassettes (inkjet-printed strips of different intensities to allow scoring on a G1-G10 scale); (3) generating a digital image of the test and control lines with quantitative interpretation using appropriate software. All techniques can be calibrated with a set of reference standards to allow appropriate quantification resulting in CCA concentration per ml urine. These are then compared with the visual scoring system of negative, trace, 1+, 2+ and 3+ signals. Endemic urine samples (n=100) were tested with POC-CCA and the results read by image processing using various computer software programmes. Results showed excellent correlations with the visual reading. In addition, 100 urine samples from different *S. mansoni* endemic areas were tested with POC-CCA using the above techniques. Overall, associations were highly significant, also in the lower intensity signals, indicating the usefulness and applicability of the different techniques in quantitation as well as for the resolve of the trace readings of the POC-CCA in different (endemic) settings.

1384

GLYCAN MICROARRAY-ASSISTED ANALYSIS OF DIAGNOSTIC ANTI-GLYCAN ANTIBODIES IN SCHISTOSOMIASIS

Cornelis H. Hokke[1], Abena S. Amoah[1], Niels C. Reichardt[2], Alan Wilson[3], Meta Roestenberg[1], Maria Yazdanbakhsh[1], Govert van Dam[1], Angela van Diepen[1]

[1]Leiden University Medical Center, Leiden, Netherlands, [2]CICbiomaGUNE, San Sebastian, Spain, [3]Centre for Immunology & Infection, University of York, York, United Kingdom

During *Schistosoma* infections, antibodies (Abs) are raised against numerous antigens expressed by parasite larvae, adult worms and eggs. A large proportion of these Abs is directed against antigenic glycans that are part of the parasite's glycoprotein and glycolipid repertoire. If and how anti-glycan antibodies might play a role in immunity to schistosomiasis

remains poorly understood. However, it is clear that serum antibodies to defined schistosome glycans may constitute valuable parameters in detecting schistosome exposure or infection, and monitoring treatment and schistosomiasis elimination programs. Through a detailed glycomics analysis of *Schistosoma mansoni* cercariae, schistosomula, adult male and female worms and eggs, we have isolated and identified hundreds of glycans from the parasite. These native parasite glycans in combination with a number of synthetic glycans related to schistosomes and other helminths were used to construct a glycan microarray covering a large portion of the potential glycan antigen repertoire of schistosomes. The microarray was used to analyse longitudinally sera from experimentally infected animals, as well as cross-sectional human cohorts from *S. mansoni* and *S. haematobium* endemic areas, with respect to IgM, IgG and IgE to each glycan motif, and in relation to infection duration, intensity and treatment. Overall, the most intense IgM and IgG responses are against a range of highly fucosylated glycans associated with cercarial and egg glycoproteins and glycolipids, but IgE responses were restricted to glycoprotein N-glycan core modifications only. We observed age-dependent differences in anti-glycan responses, especially when considering changes induced by treatment with PZQ. In general anti-glycan IgG is more sustained than IgM after treatment. Currently we are investigating the development of glycan-specific Ab responses in a controlled human *S. mansoni* infection model that has been developed at the LUMC. Detailed data on the diagnostic potential of specific anti-glycan Abs will be presented.

1385

ANNUAL VERSUS BIANNUAL MASS AZITHROMYCIN DISTRIBUTION AND SEROLOGIC MARKERS OF TRACHOMA AMONG CHILDREN IN NIGER: A COMMUNITY RANDOMIZED TRIAL

Catherine Oldenburg[1], Jessica Kim[1], Gretchen Cooley[2], Abdou Amza[3], Boubacar Kadri[3], Beido Nassirou[3], Sheila West[4], Robin Bailey[5], Jeremy Keenan[1], Bruce Gaynor[1], Thomas Lietman[1], Diana Martin[2]

[1]University of California San Francisco, San Francisco, CA, United States, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]PNSO, Niamey, Niger, [4]Johns Hopkins University, Baltimore, MD, United States, [5]London School of Hygiene & Tropical Medicine, London, United Kingdom

Annual mass drug administration (MDA) with azithromycin to affected districts to treat the causative agent, *Chlamydia trachomatis (Ct)*, is a core component of the World Health Organization's trachoma elimination strategy. In some areas, repeated rounds of annual MDA have not reached the elimination target of <5% prevalence of the clinical sign trachomatous inflammation-follicular (TF). We conducted a cluster randomized trial comparing annual azithromycin MDA to the entire community to biannual MDA to children ≤12 years of age ("targeted treatment") in a mesoendemic region of Niger (N=24 communities). After 36 months (3 treatment rounds versus 6 targeted treatment rounds), we collected dried blood spots from a random sample of 50 children aged 1 to 5 years per community. A multiplex bead assay on a Luminex 200 platform was used to measure antibody (Ab) responses against the *Ct*-derived antigens Pgp3 and CT694. We compared log-transformed quantitative Ab levels to Pgp3 and CT694 in children in communities randomized to annual versus biannual azithromycin distribution using generalized linear models with standard errors clustered by community. Of 1,005 children with serologic data, median age was 3 years and 51.4% were female. At 36 months, TF prevalence was 7.7% and ocular *Ct* prevalence was 5.2%. The prevalence of Ab positivity to Pgp3 was 27.3% and to CT694 was 23.6%. Seropositivity to Pgp3 and/or CT694 was significantly associated with TF at the individual (prevalence ratio [PR] 1.90, P<0.001) and community level (correlation coefficient 0.67, P=0.0003) and with ocular *Ct* infection at the community level (correlation coefficient 0.62, P=0.001). The probability of seropositivity increased with increasing age (PR 1.25 per one-year increase in age, P<0.001). Children in communities receiving targeted treatment had non-significantly reduced relative risk of Pgp3 (RR=0.71) and CT694 seropositivity (RR=0.81) compared to annual treatment. There was no difference in the shape of the age-seroprevalence curve between the two arms. While Ab responses were correlated with signs of trachoma, biannual MDA had no observable effect on TF prevalence.

1386

PROGRESS TOWARDS ACHIEVING TRACHOMA ELIMINATION: LONGITUDINAL TRENDS OVER SIX YEARS UNDER THE SAFE STRATEGY IN AL RAHAD LOCALITY, SUDAN

Angelia M. Sanders[1], Zeinab A. Admed[2], Balgesa Elshafie[3], Andrew W. Nute[1], Mazin Elsanosi[2], Nabil Mikhail[2], E. Kelly Callahan[1], Scott D. Nash[1]

[1]The Carter Center, Decatur, GA, United States, [2]The Carter Center, Khartoum, Sudan, [3]Federal Ministry of Health, Khartoum, Sudan

In 2009, the Sudan Federal Ministry of Health conducted a trachoma baseline survey in Al Rahad locality (district), Gedarif state, to determine if trachoma programmatic interventions were needed. The baseline prevalence of trachomatous inflammation-follicular (TF), a key programmatic indicator, was 7.1% (95% Confidence Interval (CI): 5.4-8.4%) in children ages 1 - 9 years and the prevalence of trachomatous trichiasis (TT) in those ≥15 years was 4.8% (CI: 3.3-6.8). Health education and TT surgical camps were conducted in 2012. In 2013, as part of operational research on survey methodology, a survey was conducted in 3 administrative units (sub-districts) of Al Rahad. Aggregating the data to a locality level produced a TF prevalence of 29.4% among children ages 1 - 9 years and a TT prevalence of 1.8% in those ≥15 years, demonstrating Al Rahad as the most endemic locality in Sudan. 3 rounds of mass drug administration (MDA) with azithromycin were conducted from 2015 to 2017 and a coverage survey was implemented after the last round of MDA from which the overall self-reported treatment coverage was estimated to be 76.0% (CI: 68.8-82.0%). During this period, TT surgical camps, health education and the trachoma school curriculum were also implemented in the locality. In December 2017, a multi-stage cluster random impact survey was conducted in Al Rahad, sampling 25 clusters of 25 households. The TF prevalence was 6.3% (CI: 4.0-10.0%) in children 1 - 9 years and therefore 1 additional round of MDA was required. The prevalence of TT among those ≥15 years was 0.59% (CI: 0.24-1.47) demonstrating that further surgical campaigns were required. Among children 1 - 9 years, 72.3% (CI: 60.2-81.8%) were found to be free from ocular and nasal discharge and 59.8% (CI: 44.8-73.1) of households surveyed were found to own a latrine. Conjunctival swabs collected from children ages 1 - 9 years are still being processed to estimate the prevalence of *Chlamydia trachomatis* infection. It is anticipated that the upcoming single round of MDA and surgical camps to be conducted in 2018 will enable Al Rahad to achieve the trachoma elimination target and move into surveillance mode in 2019.

1387

UNDERSTANDING AND QUANTIFYING THE COMPLEX RELATIONSHIP BETWEEN DIFFERENT DIAGNOSTIC INDICATORS FOR TRACHOMA SURVEILLANCE

Amy Pinsent[1], Robin Bailey[1], Anthony Solomon[2], David Mabey[1], Robert Butcher[1], Michael White[3], Deirdre Hollingsworth[4]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]World Health Organization, Geneva, Switzerland, [3]Institute Pasteur, Paris, France, [4]Oxford University, Oxford, United Kingdom

By 2020 the World Health Organization aims to eliminate trachoma as a public health problem in all endemic countries. The first of two steps towards achieving elimination is to reduce TF prevalence in all endemic districts to <5%. Serology has been suggested as an additional diagnostic to help confirm elimination. However, to understand observations from serological data it must be understood how estimates of transmission

intensity inferred from serological data relate to those from standard surveillance by TF or those from. In this study we used serological and epidemiological data from 6000 participants (aged 1-90 years) across 6 different regions (Nepal, Solomon Islands, Kiribati, Gambia, Ethiopia and Malawi) to understand the relationship between different diagnostic test results. We fitted sero-catalytic and antibody-acquisition models to serological data from each study-site. We quantified the relationship between: PCR and estimated sero-conversion rates and TF and sero-conversion rates (SCR) for each study-site, using a regression framework. We estimated the sample sizes required to determine the true prevalence using all 3 diagnostics. Through our estimated relationship between the 3 diagnostic indicators we suggest that for TF <5% we would expect 0.5% (Confidence interval (CI) 95%: 0-2%) of individuals in the community to test PCR positive and 7% (CI 95%: 4-9.3) of individuals to test sero-positive, with an SCR of 0.014 (Credible Interval (CrI): 0.007-0.021) year^{-1} corresponding to TF <5% in 1-9 year olds. We demonstrated that at least, if not a smaller sample size would be required to estimate the SCR (400 samples)in comparison to that needed for TF <5% (700 samples), but at least 3000 samples would be required to determine the true PCR prevalence. We provide the first estimate of an operational threshold for elimination with PCR. We quantified the relationship between all 3 diagnostics currently being considered for elimination surveillance to understand how findings from different diagnostics relate to one another, a vital step in understanding how different surveillance diagnostics can be used to complement one another.

1388

FIELD TESTING AND OPTIMIZATION OF A RAPID TEST FOR ANTIBODIES TO THE CHLAMYDIA TRACHOMATIS ANTIGEN PGP3

Sarah Gwyn[1], Harran Mkocha[2], Jessica Randall[1], Mabula Kasubi[3], Diana Martin[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Kongwa Trachoma Project, Kongwa District, United Republic of Tanzania, [3]Muhmbili University, Dar es Salaam, United Republic of Tanzania

Trachoma, caused by repeated ocular infection with *Chlamydia trachomatis* (Ct), is targeted for elimination by 2020. We have been investigating antibody responses against the Ct antigen Pgp3 as a surveillance tool using the multiplex bead assay (MBA) and a recently developed lateral flow assay (LFA). We evaluated the LFA in two villages in Kongwa district, Tanzania. Blood was collected into microtubes for field testing and onto filter paper as dried blood spots (DBS) for lab testing. All LFAs tested in the field were manufactured at CDC encased in cassettes ("standard" method); field testing was done using blood (N=506) and plasma (N=505) from the same individuals. DBS were tested at CDC by standard LFA (N=458) as well as a recently modified "dipstick" LFA (N=506). DBS were also tested by MBA (N=506). LFAs were read as positive, negative or invalid by an expert rater (rater 1) and at least one of three other raters. Interrater agreement as measured by Cohen's Kappa (κ). In field-based testing, the percent positive for blood was 42.5% (95% CI 38.2%-46.8%) and for plasma was 48.4 % (95% CI 44.0%-52.9%) by standard LFA. In lab-based testing of DBS, the percent positive for standard LFA was 44.1% (95% CI 39.4-48.8), for dipstick LFA was 44.3% (95% CI 39.9-48.8), and for MBA was 45.5% (95% CI 41.1-49.9). The percent agreement between the MBA and each type of LFA ranged from 92.3%-94.7%. In the field, agreement between raters 1 and 2 was κ=0.916 (95% CI 0.873-0.959) for plasma and κ=0.921 (95% CI 0.886-0.956) for blood and between raters 1 and 3 was κ=0.884 (95% CI 0.831-0.937) for plasma and κ=0.803 (0.740-0.865) for blood. In the lab, the agreement between rater 1 and 4 was κ=0.885 (0.836-0.934) for standard LFA and κ=0.952 (0.925-0.979) for dipstick LFA. The lower kappa (<0.9) seen with two raters suggest an automated reader may benefit the assay. Interrater agreement was best with dipstick LFA on DBS, suggesting this iteration is easiest to read. The Pgp3 LFA is a robust assay, with all iterations providing comparable community-level seropositivity data, and good performance in a dipstick format optimized for ease of manufacture and use.

PLANNING FOR TRANSITIONING SERVICES WHEN ELIMINATION THRESHOLDS ARE MET: LESSONS LEARNED FROM TRACHOMA TRANSITION PLANNING

Michaela Kelly[1], Paul Courtright[2], Stephen Mwatha[3], Helen Bokea[4]

[1]Sightsavers, Haywards Heath, United Kingdom, [2]Sightsavers Technical Lead, based at KCCO, United Kingdom, [3]Neglected Tropical Disease Unit, Ministry of Health, Nairobi, Kenya, [4]Sightsavers, Nairobi, Kenya

The work to eliminate trachoma as a public health problem has involved a large scale up of dedicated outreach services, actively searching for patients and taking specific trachomatous trichiasis (TT) management to the patients, along with various rounds of mass drug administration (MDA) with azithromycin and dedicated interventions to support behavioural change related to facial cleanliness and environmental improvement (F+E). By the time elimination thresholds for active trachoma (TF) and TT are met specific services should be integrated back into ongoing eye care, general health and WASH systems. Transition planning also serves as the link between dedicated interventions and preparation of the national verification of elimination and dossier preparation. Guidelines for planning for the effective transition of dedicated services (for TT, MDA, and F&E) back into existing government systems have been developed and deployed in a number of countries. Two large scale trachoma elimination programmes in 9 countries, have been gathering experiences on the successes (and factors contributing) and challenges of transition planning. Experience indicates that for successful post-elimination transition planning there is a need for engagement of the relevant stakeholders from the start of the programme, on-going communication at the national and district level, improved human resource management, a strong referral system, effective supply chain management procedures, and knowledge and awareness about the disease, intervention, and elimination at all levels. Challenges to transition planning have included resistance by stakeholders to the 'cessation' of dedicated services, lack of budget allocation by the ministries, lack of adequate information regarding elimination by district health authorities, and poor integration of F+E work into ongoing WASH programmes. Based upon the experiences in trachoma as well as the other NTD elimination programmes transition planning should enable countries to ensure that through the programmes themselves, the health system is strengthened and elimination is maintained.

1390

THE POPULATION-BASED PREVALENCE OF TRACHOMATOUS SCARRING IN A TRACHOMA HYPERENDEMIC SETTING: RESULTS FROM 152 IMPACT SURVEYS IN AMHARA, ETHIOPIA

Scott D. Nash[1], Caleb D. Ebert[1], Aisha E. P. Stewart[1], Eshetu Sata[2], Tigist Astale[2], Mulat Zerihun[2], Demelash Gessesse[2], Gedefaw Ayenew[2], Zebene Ayele[2], Melsew Chanyalew[3], Berhanu Melaku[2], Zerihun Tadesse[2], E. Kelly Callahan[1]

[1]The Carter Center, Atlanta, GA, United States, [2]The Carter Center, Addis Ababa, Ethiopia, [3]Amhara Regional Health Bureau, Bahir Dar, Ethiopia

Trachomatous scarring (TS) is thought to result from repeated infection with *Chlamydia trachomatis* throughout childhood, it commonly develops in late childhood in endemic settings, and it progresses throughout the lifetime. Pronounced scarring is an underlying cause of trichiasis, which can lead to blindness. Since the condition is irreversible, scarring in adults has been considered a marker of past exposure to Chlamydial infection within a population. Because early surveys demonstrated that Amhara, Ethiopia was endemic for trachoma, interventions including mass drug administration (MDA) with azithromycin were scaled up to the estimated 22 million people in all districts within the 10 administrative zones. District-level multi-stage cluster surveys were conducted in all districts between 2010-2015 after an average of 5 rounds of MDA to monitor the impact

of trachoma interventions. Before each survey round, trachoma graders participated in a 7 to 10-day training and a field reliability exam which included cases of TS. From all 152 districts in Amhara, 208,265 individuals ages ≥1 years were examined for the signs of trachoma including TS. Region-wide, the population-based prevalence of TS was 8.2%, (95% Confidence Interval [CI]: 7.8, 8.7%). Among children ages 1-9 years (n=73,406) the prevalence of TS was 1.1% (95%CI: 1.0, 1.2%), while among individuals ≥15 years (n=110,137) the prevalence was 12.6% (95%CI: 11.9, 13.3%). The zonal prevalence of TS among those ≥15 years ranged from 7.0% in South Wollo zone to 23.2% in South Gondar zone, and the district-level prevalence ranged from 0.9% to 36.9%. The prevalence of TS increased with age, reaching 22.4% among those 56-60 years and 24.1% among those ages 61-65 years, while the highest prevalence observed was among women ages 61-65 years, 26.1%. These results suggest that Amhara has had a long history of trachoma exposure, and that a large population remains at risk for developing trichiasis. It is promising, however, that children ages 1-9 years, many born after the MDA program began, have low levels of TS.

1391

DOES INFECTION AND ANTIBODY DATA ADD EVIDENCE TO THE UNDERSTANDING OF TRACHOMA PREVALENCE IN LOW ENDEMIC AREAS?

Mabula Kasubi[1], George Kabona[2], James Kalabashanga[1], Harran Mkocha[3], Mike French[4], Upendo Mwingira[5], Sheila West[6], Jeremiah M. Ngondi[7]

[1]Muhimbili University of Health Sciences, Dar Es Salaam, United Republic of Tanzania, [2]Iringa Regional Refferal Hospital, Iringa, United Republic of Tanzania, [3]Kongwa Trachoma Project, Kongwa, United Republic of Tanzania, [4]RTI International, Washington, DC, United States, [5]National Institute for Medical Research, Dar Es Salaam, United Republic of Tanzania, [6]Dana Center for Preventive Ophthalmology, Johns Hopkins University, Baltimore, MD, United States, [7]RTI International, Dar Es Salaam, United Republic of Tanzania

Trachoma is a public health problem in Mpwapwa district, Tanzania. A recent pre-validation survey done three years after stopping mass drug administration (MDA) with azithromycin suggested there was resurgence of active disease. In settings where prevalence of trachomatous inflammation-follicular (TF) is <5% and chlamydial infection is <2% evidence suggests that resurgence of active disease is unlikely to occur. Recent studies suggest that tests for chlamydial antigen can inform interruption of transmission of *Chlamydial trachomatis*. Mathematical models suggest that TF prevalence of <5% approximates to 7% chlamydial antibody sero-positivity. We aimed to investigate novel strategies for evaluating the resurgence of trachoma by testing markers for *C. trachomatis* infection and pgp3 antibodies. The study participants were children aged 1-9 years who were sampled during a routine trachoma survey. Children were examined for trachoma signs using the World Health Organization simplified grading system. Ocular swab samples were tested for chlamydial infection using Cepheid GeneXpert PCR platform. Antibodies against immunodominant antigen (*pgp3*) were detected using lateral flow-based assay (LFA). A total of 1,000 children were included in the study. The mean (standard deviation) age was 4.5(2.4) and the majority (52.7%) were male. The prevalence of TF was 10.2% (95% confidence interval [CI] 9.6-12.2). Based of TF prevalence, restarting MDA is required. The results of *C. trachomatis* infection and pgp3 are being processed and data will be presented at the conference. Analysis will include correlation of TF, infection and *pgp3*. The findings will provide evidence to support the identification of the resurgence of trachoma and monitor MDA. Further longitudinal monitoring of TF, *C. trachomatis* infection, and pgp3 will be needed to assess effect of MDA and track progress to elimination.

1392

GLOBAL BURDEN OF MALARIA AND DENGUE CO-INFECTION: A SYSTEMATIC REVIEW AND META-ANALYSIS

José Moreira, Claudio Bautista-Branagan, Otília Lupi, Patrícia Brasil, André Siqueira

Instituto Nacional de Infectologia Evandro Chagas (INI/FIOCRUZ), Rio de Janeiro, Brazil

The epidemiology and the geography of malaria-dengue co-infection are poorly understood. We conducted a systematic review and meta-analysis to determine the geographic limits of malaria and dengue co-infection and to estimate the prevalence of the co-infection. Electronic databases regardless of language were searched from inception until May 2017 for studies that reported the concurrent detection of *Plasmodium* and dengue. Each study site location was geo-coded, and Google fusion were used to generate individual maps. For the meta-analysis, we excluded case report/case series and pooled the study-specific estimates of prevalence rate using a random-effects model to obtain an overall summary estimate of the crude prevalence across studies. Data were analyzed using the statistical software Comprehensive Meta-Analysis. We identified 1718 unique papers and included 73. Malaria-dengue co-infection has been found in South and South-East Asia, Africa, and Americas regions, with 53 (72%), 10 (13.6%), and 10 (13.6%) articles, respectively. India is the country with most articles 33 (45%). Thirty-four studies included adult patients (≥18 years), while 27 studies included patients of all ages. Forty papers were eligible for meta-analysis corresponding to 19645 individuals. The proportion of malaria/dengue co-infection varies from 0.31-82%. The crude co-infection prevalence in the pooled analysis was 0.5% (95% CI 0.4-0.85) (I^2=95.3%, *p*-heterogeneity<0.0001). The most frequently reported *Plasmodium spp*. were *P. vivax* (*n*=331), followed by *P. falciparum* (*n*=141), mixed infection (*n*=12), *P. knowlesi* (*n*=4), and *P. ovale* (*n*=1). Fatal outcome was rare (*n*=4). Of the 73 studies, nine (12.3%) compared clinical and laboratory features between co-infected and either mono-infection. Evidence of the negative impact of malaria/dengue comorbidity was lacking. In conclusion, although malaria and dengue vectors are widely distributed in nature, the prevalence of co-infection is rare, heterogeneous distributed, mainly confined to South and South-East Asia; and with a predominance of *P. vivax*.

1393

ECONOMIC IMPACT OF DENGUE ON PATIENTS HOSPITALIZED IN SOUTHERN SRI LANKA - AN ANALYSIS OF DIRECT AND INDIRECT COSTS

Nayani P Weerasinghe[1], **M Ruvini P Kurukulasooriya**[1], L Gayani Tillekeratne[2], WMD Gaya B Wijayaratne[1], Champica K Bodinayake[1], I Vasantha Devasiri[1], Niroshan J Dahanayake[1], C. Lakmal Fonseka[1], Harshani Ubesekara[3], K V Thamali Anuradha[1], Aruna Dharshan de Silva[4], Bradly P Nicholson[5], Truls Østbye[2], Christopher W Woods[2], Ajith De S Nagahawatte[1]

[1]Faculty of Medicine, University of Ruhuna, Galle, Sri Lanka, [2]Duke University School of Medicine, Durham, NC, United States, [3]Provincial Director of Health Office, Galle, Sri Lanka, [4]General Sir John Kothalawale Defence University, Ratmalana, Sri Lanka, [5]Durham Veterans Affairs Medical Center, Durham, NC, United States

Dengue is an important cause of hospitalization in the tropics. The economic impact of dengue on patients has not been clearly defined in Sri Lanka. We determined costs associated with illness for patients hospitalized with dengue in southern Sri Lanka. A prospective cohort study was conducted at a tertiary and a secondary-care public hospital in Southern Province. Consecutive patients hospitalized with risk for severe dengue (platelet <100x10^9/L) were enrolled from Jun-Oct 2017. Data regarding direct patient expenditures (travel, medical visits, medications, and investigations) and indirect costs (loss of productivity) were gathered using interviews and a telephone call 2-4 weeks after discharge. Among 323 patients with dengue, 200 (61.9%) were male and median age was

33 years (IQR 25-46). Median duration of hospitalization was 4 days. Overall, 249 (77.1%) patients reported 1 to 4 prior outpatient visits for same illness: 70.3%- general practitioner, 4.0%- Outpatient Department, and 4.6%- consultant physician. Among 300 adults, 217 (72.3%) missed work (median 3 days, IQR 2-5) and among 23 children, 9 (39.1%) missed school (median 4 days, IQR 2-4) before admission. Of 77.1% who received a post-discharge call, 14 (16.5%) reported another outpatient visit and 8 (3.2%) reported another admission. Most adults (184, 80.0%) reported missing work following discharge (median 14 days, IQR 7-21) and 8 (42.1%) children reported missing school following discharge (median 14 days, IQR 5-17.5). Patients reported a total median expenditure of 2050 Sri Lankan Rupees (IQR 1000-3500) for the illness: 1350LKR (IQR 450- 2050) for medical care before admission, 0 (IQR 0-0) LKR during admission, and 800 (500- 1500) after discharge. Most expenditures were for medical visits. Given a national daily average income of 1147 LKR/ person and median values for days of work lost, 24,087 LKR in wages were lost by an adult for the illness. Dengue resulted in a significant economic burden to hospitalized patients. These data highlight the need for preventative public health actions for dengue and may help inform decisions such as vaccination or vector control activities.

1394

GAPS IN SERVICE UTILIZATION AND SERVICE PROVISION: AN ANALYSIS OF DHS AND SPA MALARIA DATA FROM MALAWI, SENEGAL, AND TANZANIA

Cameron Taylor, Anne Linn, Wenjuan Wang, Hamdy Moussa
ICF, Rockville, MD, United States

Ensuring universal access to malaria diagnosis and treatment is a key component to Pillar 1 of the WHO Global Technical Strategy for Malaria 2016-2030. To achieve this goal, it is essential to know the types of facilities where the population seeks care as well as the malaria service readiness of these facilities in endemic countries. To investigate the gaps between the seeking and provision of malaria services, we examined malaria service utilization data in children under five with fever from the household-based Demographic and Health Survey (DHS) and provision of care data from the facility-based Service Provision Assessment (SPA) from Malawi, Senegal, and Tanzania. Facility types were harmonized (considering managing authority and facility level) between DHS and SPA surveys to examine the types of facilities where people seek care and the malaria service readiness of the facilities. Facilities categorized as "malaria service ready" included those with 1) malaria diagnostic capacity through either rapid diagnostic tests or laboratory microscopy testing, 2) malaria treatment guidelines available, 3) first-line medicines available on the day of the survey, and 4) personnel recently trained in malaria diagnosis and/ or treatment. In Malawi and Tanzania, the largest proportion of children under five with fever were taken to a government health centers (39% and 25%, respectively). However, among government health center offering child curative services and/or malaria diagnosis/ treatment, 32% of those in Malawi and 20% of those in Tanzania were classified as malaria service ready. Similarly, in Senegal, 36% of children under five with fever were taken to a government health post, mobile clinic, or health hut, however, only 51% of these facilities were classified as malaria service ready. Across all three countries, the facilities with the highest level of malaria service readiness included government hospitals, although less than 10% of children in each country received care at those facilities. More focus should be given to improving the malaria service readiness in secondary health care facilities where the population is seeking care.

1395

SUBNATIONAL PROFILING USING CHI-SQUARE AUTOMATIC INTERACTION DETECTOR (CHAID) ANALYSIS TO INFORM TARGETING OF MALARIA INTERVENTIONS: A CASE STUDY FROM NIGERIA

Samantha Herrera[1], Andrew Andrada[1], Uwem Inyang[2], Yazoume Ye[1]
[1]MEASURE Evaluation, ICF, Rockville, MD, United States, [2]United States President's Malaria Initiative, United States Agency for International Development, Abuja, Nigeria

The epidemiology of malaria in sub-Saharan Africa has changed substantially over the past two decades, owing to large investments in malaria prevention and case management. Many countries have seen significant declines in malaria transmission, with several shifting to more moderate and heterogeneous transmission environments. Malaria prevention and treatment interventions have expanded, though progress has been uneven, with large variation in coverage in many countries. Given these complex and evolving settings, countries require finer-scale data to target interventions. We present results from a subnational profiling study conducted in Nigeria using 2015 Nigeria Malaria Indicator Survey data. We ran Chi-square automatic interaction detector (CHAID) models to identify the most significant predictors of intervention coverage and specific subgroups that had lower coverage of interventions. We ran models for household ownership of at least one insecticide-treated net (ITN); ITN use in children under five, pregnant women, and the general population; intermittent preventive treatment in pregnancy (IPTp) uptake; and use of artemisinin-based combination therapy (ACT) for treatment of children with fever. The CHAID models identified "region of the country" as the most significant predictor of ITN ownership (range: 55%-89%, $p<0.001$) and use across the different populations (range: general population: 21%-54%, children under five: 25%-62%, pregnant women: 28%-69%; $p<0.001$ for all models), and place of residence as the best predictor of IPTp uptake (range: 17%-27%, $p<0.001$) and use of ACT treatment (range: 13%-21%, $p<0.001$). The CHAID gain index results for each model identified key subgroups for targeted interventions. For example, the household ITN ownership model identified small households (1-4 members) in the South West, North Central, and South Central regions of the country as subgroups to target (total 40% gain percent). The use of CHAID analysis is new to the global health field and can provide valuable information for national malaria control programs on how to target interventions more efficiently to maximize impact.

1396

MAKING THE CASE FOR INVESTMENT IN SOCIAL AND BEHAVIOR CHANGE INTERVENTIONS FOR MALARIA: RESULTS FROM A SECONDARY ANALYSIS IN NIGERIA

Samantha Herrera[1], Kirsten Zalisk[1], Debra Prosnitz[1], Uwem Inyang[2], Mark Maire[3], Yazoume Ye[1]
[1]MEASURE Evaluation, ICF, Rockville, MD, United States, [2]United States President's Malaria Initiative, United States Agency for International Development, Abuja, Nigeria, [3]Division of Parasitic Diseases and Malaria, Center for Global Health, United States Centers for Disease Control and Prevention, President's Malaria Initiative, Atlanta, GA, United States

Social and behavior change (SBC) interventions have been an integral component of malaria intervention packages in Nigeria, but evidence of their effectiveness in improving uptake of malaria interventions is limited. In this study, we used 2015 Malaria Indicator Survey data to examine the relationship between maternal recall of malaria messages in the past six months and care-seeking for children under five with fever, insecticide-treated net (ITN) use in children under five, and ITN use and uptake of intermittent preventive treatment (IPTp) in pregnant women. Multiple logistic regression was conducted to assess the relationship between maternal recall of at least one specific topic-related message (e.g., "seek

treatment for fever," "sleeping inside a mosquito net is important") and the care-seeking and ITN use outcomes. A case-control study approach explored the relationship between recall of at least one malaria SBC message and IPTp uptake, with cases defined as "women who received ≥2 doses of IPTp" and controls defined as "women who had a live birth in the past two years but did not receive ≥2 doses of IPTp." Results indicate positive associations between maternal SBC recall and all measured outcomes. The odds of ITN use among children whose mother recalled an ITN message were 2.1 times greater than among children whose mother did not recall a message (OR: 2.12, 95% CI: 1.65–2.72); and the odds of ITN use among pregnant women who recalled an ITN message were 2.4 times greater than pregnant women who did not recall a message (OR: 2.42, 95% CI: 1.46–4.00). A borderline significant association was observed for care-seeking. The odds of care-seeking for children with fever were 1.7 times greater for children whose mother recalled a care-seeking message than for children whose mother did not recall a message (OR: 1.69, 95% CI: 0.94–3.04). The odds of recall of a malaria message among women who received IPTp were 1.7 times greater than among women who did not receive IPTp (OR: 1.70, 95% CI: 1.43–2.03). The results suggest an important role for SBC in Nigeria. Given low maternal recall of SBC messages (36% in 2015), efforts should be made to improve the reach of SBC.

1397

LARVAL SOURCE REDUCTION WITH A PURPOSE: DESIGNING AND EVALUATING A SCHOOL AND COMMUNITY INTERVENTION IN COASTAL KENYA

Jenna E. Forsyth[1], Francis Mutuku[2], Lydiah Kibe[3], Luti Mwashee[4], Desiree LaBeaud[1]

[1]Stanford University, Stanford, CA, United States, [2]Technical University of Mombasa, Mombasa, Kenya, [3]Kenya Medical Research Institute, Kilifi, Kenya, [4]Vector Disease Control Unit, Msambweni, Kenya

Since *Aedes aegypti* mosquitoes preferentially breed in domestic containers, control efforts focus on larval source reduction. Our objectives were to design and test the effectiveness of a school and community source reduction intervention to improve knowledge and behaviors and reduce the abundance of immature mosquitoes and household breeding sites in coastal Kenya. During a 10-month formative phase, we interviewed 80 adults and children to understand current knowledge and practices and surveyed 200 households to assess mosquito breeding. We enrolled 50 children (ages 10-16) and their parents from 5 control and 5 intervention schools. Baseline and 3-month follow-up assessments measured knowledge, behaviors, and household mosquito breeding before and after the intervention. Our formative phase indicated that source reduction awareness and behaviors were minimal, female heads of household primarily manage water containers, and more than 80% of mosquito breeding occurred in containers with no purpose. Using this information, we designed the resulting intervention to involve female heads of households during 1-hour home sessions, children during 5-hour interactive after-school lessons using games and poetry, and everyone during school recycling events to collect and reuse "no purpose" containers. By the 3-month follow-up, the intervention arm had significantly more knowledge and self-reported behavior than the control arm ($p<0.05$): 69% vs. 30% of intervention vs. control adults and 83% vs. 17% of children knew stages of the mosquito life cycle; 68% vs. 29% of adults and 41% vs. 20% of children knew how to reduce mosquito breeding; and 56% vs. 19% of adults practiced source reduction. During recycling events, participants collected 17,200 containers (1 ton of plastics) and planted 4,000 native trees. At follow-up, intervention households had fewer no purpose containers and immature mosquitoes than control households. We will assess the sustainability of outcomes after one year. Our study demonstrates that source reduction interventions can be effective if designed with an understanding of the social and entomological context.

1398

PARTNERING WITH MIDWIVES AND HEALTH CENTER PERSONNEL TO DETECT AND TREAT CONGENITAL CHAGAS DISEASE IN RURAL GUATEMALA

Pamela Pennington[1], Pamela Flores[1], Elizabeth Pellecer[1], Mabel Taracena[1], José G. Juárez[1], Joe Bryan[2], Celia Cordón-Rosales[1]

[1]Universidad del Valle de Guatemala, Guatemala, Guatemala, [2]Centers for Disease Control and Prevention Central America Regional Office, Guatemala, Guatemala

Chagas disease is a significant challenge for public health in Latin America. The incidence of new congenital infections is estimated to be 5-6.6%. In 2015, a prevalence survey of Chagas disease in Comapa, a region in Guatemala with previously high levels of triatomine infestation, revealed that 1.4% ±1% (95% CI) of children 7-14 years old and 10%±3% (95% CI) of women of childbearing age (15-44 years) are seropositive to *Trypanosoma cruzi*. We implemented a community-based program for prenatal and neonatal *T. cruzi* screening for early congenital Chagas treatment. Between 2014 and 2015, a participatory strategy was developed with midwives from high risk communities, health center personnel and other stakeholders. In 2015, 135 pregnant women attending prenatal care at the health center in Comapa were tested with a Chagas rapid antibody test, compared with 454 in 2017. Positives are confirmed by ELISA. Neonates (most within one month of birth) are now brought to the health center and screened for parasitemia through microscopic observation of heel prick blood in capillary tubes. A real-time PCR (qPCR) that targets a variable region of the minicircle is performed on blood samples preserved in nucleic acid preservation cards. In 2017, 17 neonates born to seropositive mothers were negative by microscopy. By qPCR, 3 of 9 (33%) samples are positive for *T. cruzi* DNA, with unique melting curves. Infants born to seropositive mothers will be followed at 9 months for antibody to provide treatment. Current guidelines indicate treatment only after proven parasitemia or antibody detection at nine months. Enhancing a partnership, based on the synergy of an existing social structure and local resources and processes, facilitates access to congenital Chagas detection in rural areas with low access to health services. Early detection of congenital infection and expeditious treatment of infected newborns are essential for Chagas elimination. Future efforts should promote access to treatment for seropositive women to reduce risk of congenital transmission and use of pediatric formulations to facilitate treatment of congenital disease.

1399

A NOVEL, FLUORESCENCE-BASED ASSAY TO ASSESS THE REPLICATIVE ABILITY OF *TRYPANOSOMA CRUZI* PARASITES BY DETECTION OF THYMIDINE INCORPORATION INTO PARASITE DNA

Melissa L. Sykes[1], David Hilko[1], Livia Kung[2], Sally-Ann Poulsen[1], Vicky Avery[1]

[1]Griffith Institute for Drug Discovery, Brisbane, Australia, [2]Institute of Integrative Biology, ETH Zurich, Brisbane, Switzerland

Chagas disease, caused by the protozoan parasite *Trypanosoma cruzi*, is considered one of the world's 20 most neglected tropical diseases by the World Health Organisation (WHO). *T. cruzi* is endemic to 21 countries within the Americas, infects approximately 28 000 people and causes some 12 000 deaths, per year. The drugs currently used to treat *T. cruzi* infection have questionable efficacy and associated toxicity. Inevitably, the result is ineffective or incomplete treatment, therefore new compounds are needed for the drug discovery pipeline. Attrition of compounds is an ongoing issue for Chagas discovery and improvement of *in vitro* assays to further understand the efficacy and mode of action of new compounds would support new discoveries. We have developed a high-throughput, high-content assay to assess compound activity against intracellular *T. cruzi* amastigotes utilising the fluorescent markers Hoechst and HCS

CellMask Green. To understand the replicative capability of *T. cruzi*, we have employed a fluorescent flou-488 marker to identify incorporation of a collection of 6 thymidine analogues into *T. cruzi* DNA, visualised using click chemistry. Analogues were co-incubated with intracellular *T. cruzi* parasites over time to identify 5-ethynyl-2′-deoxyuridine (EdU) as the most effectively incorporated into parasite DNA. Identification of DNA synthesis by EdU has previously been used to label replicating mammalian cells. EdU was employed to develop a novel image-based assay to assess the activity of compounds against parasite replication. The effects of the drugs used to treat Chagas disease on *T. cruzi* replication were investigated, in addition to posaconazole, which causes a sub-efficacious effect against the parasite *in vitro* and has failed clinical trials to treat Chagas disease. Active compounds against *T. cruzi* from the Medicines for Malaria Venture (MMV) Pathogen Box were also assessed for their effect upon parasite replication. This methodology provides new insights into the MOA and static/cidal nature of the action of these compounds and drugs and is a promising tool to aid the prioritisation of compounds in drug discovery.

MOLECULAR CHARACTERIZATION OF *LEISHMANIA* DNA FROM ARCHIVED GIEMSA-STAINED SLIDES OF PATIENTS FROM SALTA, ARGENTINA

Maria Cristina Almazan, Alejandro Javier Krolewiecki, Carlos Lorenzo Hoyos, Silvana Pamela Cajal, Griselda Noemi Copa, Pedro Emanuel Fleitas, Paola Andrea Barroso, Jorge Diego Marco, Julio Ruben Nasser, Jose Fernando Gil

Instituto de Investigaciones de Enfermedades Tropicales, Salta, Argentina

Cutaneous leishmaniasis is endemic in the northwestern province of Salta in Argentina. *Leishmania* DNA from Giemsa-stained slides of up to 12 years in storage of patients from a University based reference center in Oran, Salta was characterized through PCR-Restriction Fragment Length Polymorphism (RFLP). One hundred smears from individuals with suspicious lesions and epidemiologic exposure plus microbiologic confirmation through positive microscopy were analyzed. The samples had been originally taken 2, 3, 5, 6 and 12 years prior to performing PCR-RFLP (20 samples from each year) and were maintained at room temperature in a tropical environment. All the cases were classified in a semiquantitative scale for amastigote density, and Leishmanin skin test (LST) results were included. DNA extraction was done applying lysis buffer with proteinase K, and then DNA was amplified with ribosomal internal transcribed spacer 1(ITS1) primers. PCR products were digested with HaeIII enzyme. All PCR positive smears (74/100) belonged to *Viannia* subgenus. A statistically significant directly proportional relationship between semiquantitative microscopy and PCR results was detected ($p < 0.001$). All patients had LST positive results (induration ≥ 5 mm), and the smears of those with positive but smaller induration (LST < 19 mm) had a higher proportion of positive PCR results. This study determined that smear age did not affect PCR positivity, which allows retrospective analyzes and suggests smears might be useful for molecular complementary diagnosis. Since *Leishmania* (*Viannia*) *braziliensis* is the main circulating species in the study area, determining *Viannia* subgenus in all analyzed samples confirms previous findings. PCR positivity showed statistically significant differences according to semiquantitative microscopy, highlighting the importance of parasite burden in the diagnostic sensitivity of the method. Considering that smears of patients with smaller LST induration were more positive in PCR, a negative smear from patients with positive LST response, but < 19 mm, could actually represent a false negative smear result.

1401

PREVALENCE AND ASSOCIATION OF *LEISHMANIA* RNA VIRUS-1 (LRV-1) IN SEVERE AND NON-SEVERE PHENOTYPES OF AMERICAN TEGUMENTARY LEISHMANIASIS FROM PERU

Ruwandi Kariyawasam[1], Rachel Lau[2], Braulio M. Valencia[3], Alejandro Llanos-Cuentas[4], Andrea K. Boggild[1]

[1]University of Toronto, Toronto, ON, Canada, [2]Public Health Ontario, Toronto, ON, Canada, [3]Instituto de Medicina Tropical, Lima, Peru, [4]Instituto de Medicina Tropical "Alexander von Humboldt", Lima, Peru

American tegumentary leishmaniasis (ATL) comprises a discrete set of clinical presentations of leishmaniasis endemic to Latin America. *Leishmania* RNA virus-1 (LRV-1) is a double stranded RNA virus identified in 20-25% of the *Leishmania Viannia* complex, and is believed to be a predictive biomarker of severe ATL. Our objective was to determine the baseline prevalence of LRV-1 and associations with clinical phenotypes in ATL patients from Peru. Banked clinical isolates of patients residing in or traveling to Peru between 2006 and 2016 were species identified by PCR, RFLP analysis, and Sanger sequencing, and screened for LRV-1 by real-time PCR. Patient isolates were stratified according to clinical phenotype: localized cutaneous leishmaniasis (LCL) was defined as "non-severe" ATL, whereas "severe ATL" was defined as mucosal or mucocutaneous leishmaniasis (ML/MCL); erythematous, purulent, or painful ulcers and/or lymphatic involvement (inflammatory ulcers); or multifocal/disseminated ulcers (greater than 4 in greater than 2 anatomic sites). Of 132 patients enrolled, 64 (48%) and 68 (52%) of ATL cases had the severe and non-severe phenotypes, respectively. Twenty-seven (42%) of 64 severe ATL cases and 29 (43%) of 68 non-severe ATL cases were positive for LRV-1, respectively ($p=1.00$). The severe phenotype was over-represented among older patients (median age 41.5 years vs. 29 years in non-severe ATL, $p=0.0002$), while the median age did not differ by LRV-1 status ($p=0.27$). A trend in disease severity was observed by sex, whereby 62 (59%) males had a severe phenotype compared to 10 (37%) females ($p=0.05$). No difference in LRV-1 status was observed by sex ($p=0.50$). Twenty-three (41%) of 56 quantified LRV-1 positive patients revealed greater LRV-1 copy numbers in those with ML/MCL compared to those with all forms of CL ($p=0.04$). Our findings suggest age as a contributing factor to disease severity. Although an association between LRV-1 status was clinical phenotype was not demonstrated, LRV-1 copy number was higher in patients with ML/MCL. Therefore, the role of LRV-1 viral burden in severe disease requires further exploration.

TRANSCRIPTOME ANALYSIS OF SPLENIC ASPIRATES IN HUMAN VISCERAL LEISHMANIASIS REVEALS IMPAIRED TISSUE ORGANIZATION/REPAIR AND INHIBITED PARASITE KILLING

Margaret Mbuchi[1], **Elvia Y. Osorio**[2], Omar A. Saldarriaga[2], A. Muia[1], C. Magiri[1], H. Kanyi[1], A. Chelugo[1], A. Muthoni[1], R. Rono[1], S. Gachigi[1], S. Njenga[1], M. Wasunna[1], Bruno L. Travi[2], Peter C. Melby[2]

[1]Kenya Medical Research Institute, Nairobi, Kenya, [2]University of Texas Medical Branch, Galveston, TX, United States

Changes in the spleen environment that contribute to the pathogenesis of human visceral leishmaniais (VL) are under explored. We performed transcriptional profiling (RNAseq) on the remnants of diagnostic splenic aspirates from 8 Kenyan patients with visceral leishmaniasis. Differentially expressed genes were identified by comparison to splenic RNA from normal controls obtained through commercial sources. A total of 2,749 differentially expressed genes were identified with a cutoff of as 2-fold change and false discovery rate (FDR) ≤0.05. Functional analysis was done with the Ingenuity Pathways Analysis (IPA) software. We found that half of the top 10 down-regulated canonical pathways were related to cell assembly and organization with decreased expression of actin, integrins

and cadherins. Decreased expression of extracellular matrix proteins (ECM), vitronectin, fibronectin, collagen and endothelins indicated defects in ECM and decreased tensile strength of the tissue. IL8 signaling was a highly down-regulated pathway, which together with the ECM changes, would lead to impaired neutrophil recruitment, transmigration, and activation. Pathways involved in Leishmania killing, including production of nitric oxide and NFkB signaling were also represented in 2 of the top 10 canonical pathways that were inhibited. Transcript expression was compatible (Z<-2.0) with impaired tissue repair and healing (decreased angiogenesis, lymphangiogenesis, endothelial cell development and connective tissue differentiation). In contrast, functions predicted to be activated (Z>2.0) indicated tissue damage (mediated by upstream gene regulators IFNγ, TNFα and CxCL10), bleeding (by coagulation system defects), dysgenesis, and edema. Collectively these data indicate that impaired splenic tissue organization and repair is likely to be part of the pathogenesis of human VL.

CHAGAS DISEASE-INDUCED FUNCTIONAL PERTURBATIONS OF THE GASTROINTESTINAL MICROBIOME

Laura-Isobel McCall[1], Ekram Hossain[1], Anupriya Tripathi[2], Fernando Vargas[2], Rob Knight[2], Pieter C. Dorrestein[2], Jair L. Siqueira-Neto[2]

[1]University of Oklahoma, Norman, OK, United States, [2]University of California San Diego, La Jolla, CA, United States

Chagas disease is a tropical disease endemic to Latin America, caused by infection with *Trypanosoma cruzi* parasites. Six to seven million people are *T. cruzi*-positive, thirty to forty percent of which will develop cardiac symptoms, including arrhythmias, aneurysms and fatal heart failure. A minority of patients will develop gastrointestinal manifestations (megaoesophagus and megacolon), alone or in combination with cardiac symptoms. Gastrointestinal tissues are also a major site of chronic parasite persistence, in mouse models of disease, and may serve as reservoir for cardiac re-seeding following unsuccessful treatment. However, the pathogenesis of gastrointestinal Chagas disease is still poorly understood. To address this, we performed joint microbiome and metabolome characterization of fecal samples over the course of experimental acute and chronic Chagas disease, using 16S rRNA sequencing and liquid chromatography-tandem mass spectrometry. These results showed functional changes in the fecal microbiome, beginning in the acute stage prior to peak parasite burden. Importantly, these changes persisted in the chronic stage of disease. Alterations include perturbations in conjugated linoleic acid (CLA) derivatives and in specific members of families *Ruminococcaceae* and *Lachnospiraceae*, as well as changes in secondary bile acid levels and members of order Clostridiales, all of which could have local as well as systemic effects on *T. cruzi* persistence and inflammation. In addition, we assessed microbial and metabolic changes systematically throughout the gastrointestinal tract. This enabled us to build a three-dimensional model of functional microbiome disturbances, in correlation with localized parasite burden. The greatest microbial disruptions were observed in the colon, where parasite burden was the highest, and in the esophagus, in association with changes in small molecule profile. Overall, these results are expanding our understanding of Chagasic megacolon and megaoesophagus pathogenesis, with great potential for the development of novel intervention strategies against this neglected tropical disease.

MODELLING THE EFFECTS OF ATTRACTIVE TOXIC SUGAR BAITS (ATSBS) ON MALARIA PREVALENCE IN HUMANS; A TOOL FOR EPIDEMIOLOGICAL STUDY DESIGN

Keith J. Fraser, Azra C. Ghani

Imperial College London, London, United Kingdom

Attractive toxic sugar baits (ATSBs) are a promising new tool for malaria control as they can potentially target outdoor-feeding mosquito populations, in contrast to the current vector control tools which predominantly focus on indoor-feeding mosquitoes. A Phase II efficacy trial with entomological endpoints is currently underway in Mali. To inform the design of subsequent Phase III epidemiological trials, we developed mathematical models to explore the potential impact on human endpoints of ATSBs in different transmission settings. A critical parameter determining efficacy is the sugar-feeding rate, which can vary between locations (due to availability of other food sources) and seasonally (due to variation in abundance of vegetation with rainfall). In a moderate-to-high-transmission setting such as Mali, with a 3-4 month peak transmission season and an annual average human prevalence in 2-10 year olds (PrP_{2-10}) of 50%, a sugar-feeding rate of 0.4/day (similar to that estimated from past field trials) is predicted to reduce the year-round average mosquito density in the second year of ATSB implementation by ~90% compared to the pre-intervention average. Because the increase in death rate caused by ATSBs induces a greater reduction in the population of older mosquitoes, we predict a higher reduction in EIR (>99.9%) and hence a ~92% reduction in PrP_{2-10}. Smaller but still significant effects on PrP_{2-10} are predicted with a lower sugar feeding rate (~90% for a rate of 0.2/day, ~68% for a rate of 0.1/day, ~36% for a rate of 0.05/day). Higher sugar feeding rates during the dry season and lower rates during the rainy season are predicted to modify the impact whilst movement of mosquitoes from untreated into treated areas is also expected to reduce the overall efficacy. Further outputs for a range of locations and additional human endpoints such as clinical incidence will be presented, allowing a full exploration of the potential impact of this new vector control tool across malaria-endemic settings.

1405

SIMULATION STUDIES TO QUANTIFY THE IMPACT OF COMPETING RISK EVENTS IN A HYPOTHETICAL SCENARIO OF FALLING ANTIMALARIAL DRUG EFFICACY IN SINGLE-ARMED AND COMPARATIVE DRUG TRIALS

Prabin Dahal[1], Philippe J. Guerin[1], Ric N. Price[1], Julie A. Simpson[2], Kasia Stepniewska[1]

[1]WorldWide Antimalarial Resistance Network, Centre for Tropical Medicine and Global Health, Nuffield Department of Clinical Medicine, University of Oxford, Oxford, United Kingdom, [2]Centre for Epidemiology and Biostatistics, Melbourne School of Population and Global Health, The University of Melbourne, Melbourne, Australia

A new infection (NI) can potentially preclude the occurrence of a subsequent recrudescence, thus constituting a competing risk event (CRE). In the presence of CRE, the complement of the Kaplan Meier (K-M) estimate is known to result in an overestimate of failure. The overall aim of this simulation work was to quantify the bias in derived failure due to the use of the K-M method (which censors NI) compared to the Cumulative Incidence Function (CIF) approach (which considers NI as a CRE), and to assess the impact of CRE on comparative efficacy. A clinical trial (n=500 patients) was simulated with 5, 10 and 15% documented recrudescences. For each scenario, different proportions of NI were simulated to represent areas of progressively increasing transmission (<10%, 10-20%, 20-40% and >40%). Time to recrudescence and NI were simulated using biologically plausible hazard functions. For comparative studies, nine different scenarios which could be observed in a field trial when comparing two drugs (drug A and drug B) were simulated. For each of these scenarios, log-rank test for comparing the equality of K-M curves and Gray's test for comparing the equality of the CIFs were used. In single-armed trial, the overestimation of failure by the K-M method increased with increasing proportion of NI. In high transmission areas, the maximum overestimation in efficacy was 0.75% at 5% recrudescence and this rose to 3.1% and 4.3% when the drug efficacy fell to 90% and 85% respectively. In comparative trial, where drug B was associated with 2-fold increase in both recrudescence and NI (compared to drug A), the log-rank test appeared to be the more powerful test with a rejection probability of 99% compared to 90% with Gray's test. However, when drug B exerted differential effect on recrudescence and NI (i.e. reduced

recrudescence but increased NI), the Gray's test was the more powerful of the two tests. In high transmission areas, where the risk of new infection is high, the competing risk analysis approach should be used for deriving failure estimates. For comparative trials, the choice of the test to establish difference should be guided by the research question of interest.

1406

MULTIPLE FIRST LINE THERAPIES VERSUS REDUCING OVERPRESCRIPTION OF ANTIMALARIALS TO SLOW ANTIMALARIAL RESISTANCE

Lucy Okell, Oliver Watson

Imperial College London, London, United Kingdom

The emergence of artemisinin and partner drug resistance prompts examination of which strategies can best delay or prevent the spread of resistance. It is unlikely that countries can implement all strategies simultaneously given resource constraints. Some countries are adopting a policy of multiple first-line therapies (MFT), where different patients are allocated to different ACTs, to increase the diversity of selective pressures acting on the parasite. However, there are barriers to implementing MFT, in particular the logistics of distribution as well as patient acceptance. Another measure, which many countries are also implementing, is to reduce overprescription of antimalarials, which can occur in the absence of diagnostic tests. We use model-based analysis to investigate whether reducing overprescription of antimalarials could be as effective as MFT in delaying drug resistance. We developed an individual based model of malaria transmission incorporating treatment with combination therapies, malaria parasites with different genotypes (wild type, resistant to each possible combination of antimalarials), heterogeneity in exposure to infectious bites, immunity to clinical manifestations of malaria, and fitness costs of resistance. We varied key parameters such as treatment coverage, the proportion of infections which develop symptoms, and the degree of resistance to each strain. We quantified the effectiveness of each strategy as the cumulative number of treatment failures over time. Initial results show that reducing overprescription of antimalarials is predicted to have more relative effect in delaying resistance in high transmission areas, where selection occurs during reinfection. The effect of reducing overprescription is small in low to moderate transmission areas. There is a non-linear relationship between treatment coverage with any one drug among clinical cases, and time to reach 10% resistance, such that if it were possible to use 5 or more different drugs for MFT, resistance development may be substantially delayed. Ongoing analysis will compare the benefits of the two strategies under different scenarios.

PHARMACOKINETIC/PHARMACODYNAMIC MODELING TO OPTIMIZE DIHYDROARTEMISININ-PIPERAQUINE EXPOSURE AND PREVENT SELECTION FOR MARKERS OF DECREASED ANTIMALARIAL DRUG SENSITIVITY DURING INTERMITTENT PREVENTIVE TREATMENT DURING PREGNANCY

Erika Wallender[1], Nan Zhang[1], Melissa Conrad[1], Abel Kakuru[2], Prasanna Jagannathan[3], Mary Muhindo[2], Patrick Tumwebaze[2], Richard Kajubi[2], Daniel Mota[1], Jenny Legac[1], Diane Havlir[1], Moses Kamya[2], Grant Dorsey[1], Francesca Aweeka[1], Philip J. Rosenthal[1], Rada Savic[1]

[1]University of California San Francisco, San Francisco, CA, United States, [2]Infectious Diseases Research Collaboration, Kampala, Uganda, [3]Stanford University, Palo Alto, CA, United States

Dihydroartemisinin-piperaquine (DP) is under study for intermittent preventive treatment during pregnancy (IPTp), but its use may accelerate selection for drug resistance. We aimed first, to define the relationship between piperaquine (PQ) exposure and genetic markers associated with decreased drug susceptibility, and second, to predict optimized DP dosing regimens to minimize risk of resistance. Clinical data, PQ concentrations, and *P. falciparum* genotypes associated with decreased PQ sensitivity in Africa (*pfmdr1* 86Y, *pfcrt* 76T) were obtained from pregnant Ugandan women who received IPTp with sulfadoxine-pyrimethamine (SP) every 8 weeks (n=106), DP every 4 weeks (n=100), or DP every 8 weeks (n=94). Joint pharmacokinetic/pharmacodynamic models were developed to describe the relationship between PQ concentration and the probability of detecting genotypes of interest using nonlinear mixed effects modeling; monthly, weekly, and daily DP regimens were simulated. Increasing PQ concentration was associated with a log-linear decrease in detection of parasitemia. Higher median PQ concentrations were needed to provide 99% protection against mutant infections as compared to wild type (N86: 7.2 ng/mL; 86Y: 10.8 ng/mL; K76: 4.9 ng/mL; 76T: 11.0 ng/mL). The median percentage of time at risk (PQ levels below those offering 99% protection) with monthly DP was 4.2% (interquartile range (IQR): 0-21%) for *pfmdr1* N86, 34% (IQR: 9.3-52%) for *pfmdr1* 86Y ($p<.01$), 0% (IQR: 0-2.6%) for *pfcrt* K76, and 31% (IQR: 10-54%) for *pfcrt* 76T ($p<.01$). Daily low dose DP was predicted to reduce the median percentage of time at risk for any parasitemia to <1% and to result in the fewest mutant infections (episodes of *pfmdr1* 86Y parasitemia per 1,000 pregnancies: SP: 332, monthly DP: 190, weekly DP: 52, daily DP: 0). Our models predict that 1) higher PQ concentrations are needed to prevent infections with mutant compared to wild type parasites, 2) the overall burden of infections with mutant parasites is lower for DP than SP, and 3) daily low dose DP best reduced the estimated number of mutant infections. Consideration of dose optimization of DP for IPTp in Africa is warranted.

1408

PHARMACOKINETIC-PHARMACODYNAMIC MODELLING OF ARTESUNATE IN PATIENTS WITH DRUG RESISTANT AND SENSITIVE MALARIA (TRAC)

Richard Hoglund[1], Tracking Resistance to Artemisinin Collaboration[2]

[1]Department of Clinical Pharmacology, Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand, Thailand, [2]Worldwide collaboration, International, Thailand

The emergence of artemisinin resistance in Southeast Asia is a substantial threat to currently used antimalarial therapies and it is important to optimize current treatments to maximize therapeutic efficacy. This project aimed to investigate the pharmacokinetic and pharmacodynamic properties of artesunate, and to quantify the impact of resistance on therapeutic outcome. Pharmacokinetic and pharmacodynamic data presented here were generated from the Tracking Resistance to Artemisinin Collaboration (TRAC). Hitherto, this is the largest study ever conducted, investigating the pharmacokinetic and pharmacodynamic properties of artesunate. A total of 1,180 patients in Asia and Africa with uncomplicated *falciparum* malaria, receiving daily monotherapy of artesunate for three days, contributed data to this analysis. Densely collected plasma concentrations of artesunate and dihydroartemisinin, microscopy parasite counts and molecular markers for drug resistance were collected and analysed using nonlinear mixed-effect modelling. Artesunate and dihydroartemisinin pharmacokinetics were well-described by a parent-metabolite model, assuming full *in-vivo* conversion of artesunate into dihydroartemisinin. Parasite density measurements were modelled using a fixed 10-fold multiplication growth rate per parasite life-cycle. The elimination of parasites was dependent on the concentration of dihydroartemisinin and was described by an E_{MAX} model. Mutation of the K13-propeller, associated with reduced drug susceptibility, had a significant impact on the maximum effect, resulting in a slower killing of parasites in patients with drug resistant infections. The developed model was used to simulate different treatment alternatives for patients with artemisinin resistant infections, demonstrating that an increased treatment duration of current combination therapy is necessary in these patients. Alternatively, triple combination of antimalarial drugs are under evaluation to treat resistant infections.

1409

SCHOOL-BASED ANTIMALARIA INTERVENTIONS EFFICIENTLY REDUCE COMMUNITY-LEVEL *PLASMODIUM FALCIPARUM* PREVALENCE IN A HIGH-TRANSMISSION SETTING: A MATHEMATICAL MODELING STUDY

Andrea Geri Buchwald[1], Jenna E. Coalson[2], Lauren M. Cohee[1], Mark L. Wilson[3], Laura L. Hungerford[4], Terrie E. Taylor[5], Miriam K. Laufer[1]

[1]University of Maryland Baltimore, Baltimore, MD, United States, [2]The University of Arizona, Tucson, AZ, United States, [3]University of Michigan, School of Public Health, Ann Arbor, MI, United States, [4]Virginia-Maryland College of Veterinary Medicine, Blacksburg, VA, United States, [5]Michigan State University College of Osteopathic Medicine, East Lansing, MI, United States

Global antimalaria scale-up has significantly decreased malaria morbidity and mortality in many regions of the world. However, countries with the highest *Plasmodium falciparum* transmission have seen the slowest declines in malaria disease incidence and infection prevalence. In Malawi, uptake of antimalaria interventions is high among groups with the highest burden of disease (pregnant women and under-five children). Most *P. falciparum* infections, however, occur in school-aged children (5-15 years old) and prevention efforts have not been effective at reducing infection prevalence among this group. School-aged children are also less likely to receive anti-*P. falciparum* treatment, as many school-aged children's infections are asymptomatic. By targeting this highly-infected group, school-based interventions may be a cost-effective approach to reduce population-level transmission. We used a differential equation-based, deterministic, compartmental simulation model to evaluate how school-based interventions might affect community-level *P. falciparum* prevalence compared to current strategies (targeting pregnant women and under-five children) or community-based application of mass drug administrations (MDA) and mass screen-and-treat (MST) programs. The model, which accounted for asymptomatic infections, was fit to data from cross-sectional surveillance and longitudinal cohort studies in southern Malawi. We aimed to achieve a 50% decrease in community malaria prevalence while minimizing the number, frequency, and coverage of treatment campaigns as well as minimizing the number of individuals treated. The decrease in community infection prevalence was greatest when interventions were distributed randomly throughout the community. However, school-based interventions led to greater decreases in prevalence than MDA or MST targeting under-five children and pregnant women. While school-based interventions may not produce the greatest decrease in community infection prevalence, their comparative efficiency and potential cost-effectiveness may make them a better strategy for future malaria control programs.

1410

PROBABILISTIC MODEL OF *PLASMODIUM VIVAX* RELAPSE FOR IMPROVED ESTIMATION OF TREATMENT EFFICACY USING TIME-TO-RECURRENCE DYNAMICS

James Watson[1], Aimee R. Taylor[2], Caroline O. Buckee[2], Mallika Imwong[3], Cindy S. Chu[1], Nicholas J. White[1]

[1]Oxford University, Oxford, United Kingdom, [2]Harvard University, Boston, MA, United States, [3]Mahidol University, Bangkok, Thailand

Plasmodium vivax causes most of the malaria outside Sub-Saharan Africa. Vivax malaria in South East Asia exhibits the frequent relapse phenotype, with infections recurring at short intervals (3-4 weeks). As relapses from liver stage hypnozoites cannot be distinguished genetically from reinfections the radical curative efficacy of primaquine can only be characterized properly with placebo controlled trials (i.e. randomization to no radical cure) which is not possible in many countries where the standard of care includes radical cure. Data from a three way randomized controlled trial (n=600) comparing chloroquine (a slowly eliminated blood stage drug), chloroquine and primaquine together, and artesunate monotherapy (which is rapidly eliminated) were used to fit a Bayesian hierarchical model to the times to recurrent episodes (>1300 episodes recorded) conditioned on the treatments given. The relapse hazard rate is non-constant after acute vivax malaria. Tropical frequent relapse *P. vivax* on the Thai-Myanmar border area was well described by a triple mixture model with a relapse component (exponential waiting time), a `rapid' relapse component (normally distributed), and a `slow' relapse component (exponential waiting time). Time to recurrent episode provides discriminatory information between relapse and reinfection, thus providing a probabilistic framework for adjusting radical cure efficacy.

1411

NEUTROPHILS INFLUENCE ANTIGEN PRESENTATION DURING IMMUNE RESPONSE TO LIVE ATTENUATED LEISHMANIAL VACCINE

Parna Bhattacharya[1], Pradeep Dagur[2], Nevien Ismail[1], Kazuyo Takeda[1], Ranadhir Dey[1], Hira Nakhasi[1]

[1]Food and Drug Administration, Silver Spring, MD, United States, [2]National Institutes of Health, Rockville, MD, United States

No vaccine exists against Visceral Leishmaniasis. We have earlier reported the protective role of live attenuated centrin gene deleted *L. donovani* (*LdCen*$^{-/-}$) parasite vaccine in animal models. *LdCen*$^{-/-}$ induces strong innate immunity leading towards protective Th1 response. Neutrophils are indispensable for first line of defense against pathogens. Additionally, role of neutrophils as antigen presenting cells (APCs) has been demonstrated in enhancing virus based vaccine induced responses and tuberculosis vaccination. Emerging evidence suggests that neutrophils should be considered as important modulators of leishmaniasis. Although studies have shown the importance of neutrophils during *Leishmania* infection, none have shown its role in development of specific response to a Leishmania vaccine. Hence, we studied the role of neutrophils as APCs in the induction of specific response to *LdCen*$^{-/-}$ intradermal vaccination. Increased neutrophil migration with heightened microbicidal attributes was observed after infection with *LdCen*$^{-/-}$ compared to *LdWT in vitro*. *LdCen*$^{-/-}$ infection induced TLR activation and *NF-KB* pathway induction in macrophages was found to be essential for higher neutrophil recruitment in response to infection . Likewise, *in vivo* study showed that intradermal injection with *LdCen*$^{-/-}$ induces higher neutrophil recruitment at the site of injection (ear) and lymph nodes compared to *LdWT* parasites. Phenotypic characterization of recruited dermal neutrophils revealed the presence of heterogeneous neutrophil population. Low density neutrophils sort selected from *LdCen*$^{-/-}$ infected mice exhibited attenuated expression of pro-parasitic molecules compared to *LdWT*. Adoptive transfer of *LdCen*$^{-/-}$ parasite bearing neutrophils were able to induce heightened Th1 differentiation in visceral organs compared to *LdWT* thereby highlighting the robust APC feature of neutrophils in *LdCen*$^{-/-}$ induced immunity. Also, the engulfment of *LdCen*$^{-/-}$ parasitized neutrophil by dendritic cells (DCs) enhanced Ag presentation capability of DCs compared to *LdWT*. Thus neutrophils play novel role in shaping early vaccine immunity.

1412

PHARMACOKINETIC-PHARMACODYNAMIC ASSESSMENT OF THE SAFETY OF FEXINIDAZOLE FOR THE TREATMENT OF HUMAN AFRICAN TRYPANOSOMIASIS

James Watson[1], Nathalie Strub-Wourgraft[2], Antoine Tarral[2], Joel Tarning[1], Nicholas J. White[1]

[1]Oxford University, Oxford, United Kingdom, [2]Drugs for Neglected Diseases initiative, Geneva, Switzerland

Fexinidazole is a new oral treatment for *Trypanosoma brucei* (*T.b. gambiense*) human African trypanosomiasis (g-HAT). Fexinidazole *in vitro* is also active against other human kinetoplastid parasites, *T. cruzi* and *Leishmania donovani,* the causative agents of Chagas disease and visceral leishmaniasis, respectively. During a dose-ranging study conducted

in asymptomatic Bolivian Chagas patients, delayed neutropenia and significant increases in hepatic transaminases were observed and the clinical study was suspended. We analysed retrospectively all available pharmacokinetic (PK) and pharmacodynamic (PD) data on fexinidazole in healthy volunteers, Chagas patients and HAT patients to characterise the PK-PD relationships for oral fexinidazole in different regimens. A population PK model was fitted to data from three Phase I studies, two g-HAT field trials and one Chagas field trial. Bayesian exposure-response models were fitted to haematological indices and liver related PD outcomes in asymptomatic Chagas patients. These models were compared with observed data from the g-HAT trials and used to predict likely adverse events from the recommended g-HAT regimen. Asymptomatic delayed neutropenia and thrombocytopenia, and elevations in liver transaminases were found to be exposure related and thus dose-dependent in asymptomatic Chagas patients. Mild, asymptomatic haematological outcomes consistent with the exposure-response curves were observed in the g-HAT trials, confirming a haematological effect of fexinidazole. However, liver toxicity and biochemistry abnormalities were not observed in healthy volunteer studies nor in any g-HAT trials. Fexinidazole treatment results in a dose dependent delayed and reversible bone marrow suppression. The currently recommended g-HAT regimen (adult dose 1800mg for 4 days, then 1200mg for 6 days) provides exposures within a satisfactory safety margin for both neutropenia and hepatotoxicity. Liver toxicity appears to be specific to the Chagas population.

1413

INTERROGATING CHAGAS ANTIBODY RESPONSES WITH HIGH-THROUGHPUT PRECISION TOOLS: TOWARDS A COMPREHENSIVE CATALOG OF *TRYPANOSOMA CRUZI* ANTIGENS AND EPITOPES ACROSS AMERICA.

Alejandro D. Ricci[1], Janine Ramsey[2], Jaime Altcheh[3], Norival Kesper Jr[4], Melissa Nolan[5], Patricio Diosque[6], Juan C. Villar[7], Carlos A. Buscaglia[1], Fernán Agüero[1]

[1]Instituto de Investigaciones Biotecnológicas, UNSAM, San Martin, Provincia de Buenos Aires, Argentina, [2]Instituto Nacional de Salud Pública, Tapachula, Chiapas, Mexico, [3]Hospital de Niños Ricardo Gutiérrez, Ciudad Autónoma de Buenos Aires, Argentina, [4]Instituto de Medicina Tropical, Universidade de São Paulo, São Paulo, Brazil, [5]Baylor College of Medicine, Houston, TX, United States, [6]Instituto de Patología Experimental, Facultad de Ciencias de la Salud, Salta, Argentina, [7]Universidad Autónoma de Bucamaranga, Santander, Colombia

Using state of the art high-density peptide microarrays, we developed a highly multiplexed screening array design containing ~2.8 million unique peptides derived from the complete proteomes of Trypanosoma cruzi strains CL-Brener (hybrid DTU TcVI; 19,668 proteins) and Sylvio X10 (DTU TcI, 10,832 proteins). The full length of all 30,500 proteins encoded in these genomes were scanned using 16mer peptides with an overlap of 12 residues between each peptide. Using this platform, we screened sera pools from Chagas-positive and healthy volunteers from several regions across America: Argentina, Brazil, Colombia, Mexico and the United States. Screening of negative sera pools from healthy subjects allowed us to define a background baseline of antibody-binding signal against peptides, as well as to identify cross-reactive epitopes. Screening of Chagas-positive sera pools allowed us to identify specific antibody-binding against *Trypanosoma cruzi* peptides. Using a conservative signal threshold to define antigenic peaks in proteins, our analysis led to the discovery of more than 4,500 antigens (mostly novel), and to the identification of 22,747 antibody-binding peaks (epitopes) across all samples. Also, the comparative analysis of antibody-binding in different samples allowed us to define a core set of pan-Chagas antigens and epitopes with reactivity in all human samples, as well as sets of unique/differential antigens (only reactive in one population) or antigens with shared reactivity in a few samples (populations). In the presentation we will highlight interesting cases of shared/differential antibody responses in different samples, and will discuss next steps to use this high-throughput platform to decompose the sera pools and gain insights into the seroprevalence of these epitopes in each population. To the best of our knowledge this is the first proteome-wide catalog of antigenic determinants for a human infectious disease.

EVALUATION OF A LOOP-MEDIATED ISOTHERMAL AMPLIFICATION (LAMP) KIT AS A MOLECULAR DIAGNOSTIC TEST FOR CONGENITAL CHAGAS DISEASE

Albert Picado[1], Susana A. Besuschio[2], Ismael Ibañez[3], Israel Cruz[1], Alejandro Benatar[2], Montserrat Gállego[4], Carme Muñoz[5], Joseph M. Ndung'u[1], Alejandro G. Schijman[2], Maria D. Flores-Chávez[3]

[1]FIND, Geneva, Switzerland, [2]Laboratorio de Biología Molecular de la Enfermedad de Chagas, INGEBI-CONICET, Buenos Aires, Argentina, [3]Instituto de Salud Carlos III, Madrid, Spain, [4]Facultat de Farmacia, Universitat de Barcelona, Barcelona, Spain, [5]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Molecular tests are used to diagnose congenital Chagas disease in some countries, mainly in Europe. Their use in endemic countries is still anecdotal. Technical and economic factors have been put forward to explain the poor penetration of molecular tests to diagnose Chagas disease in low and middle-income countries (LMIC). The use of loop-mediated isothermal amplification (LAMP) methods may overcome some of these limitations. A newly developed LAMP kit designed for detection of *Trypanosoma cruzi* DNA in human blood showed a good analytical performance and was easy to use. We evaluated the performance of a *T. cruzi* LAMP kit in stored clinical samples of congenital Chagas disease cases in Argentina and Spain. Clinical samples from 49 congenital Chagas disease cases (10 from Argentina and 39 from Spain) and 74 controls (26 from Argentina and 48 from Spain) were tested by the *T. cruzi* LAMP kit and qPCR. The *T. cruzi* LAMP results were read by naked eye and fluorimeter. The sensitivity and specificity of the *T. cruzi* LAMP was estimated using the standard case definition as reference e.g. baby with a positive microscopy, or culture between 0 and 1 months, or a positive serology for congenital Chagas disease at 9-10 months. We evaluated the agreement between *T. cruzi* LAMP read by naked eye and fluorimeter and between *T. cruzi* LAMP and qPCR using Cohen's kappa statistics (K). The sensitivity of *T. cruzi* LAMP was 98.0% (95% CI: 89.3 – 99.6%) both by naked eye and fluorimeter. Specificity was 93.2% (95% CI: 85.1 – 97.1%) by naked eye and 94.6% (95% CI: 86.9 – 97.9%) by fluorimeter. The sensitivity and specificity of *T. cruzi* LAMP improved when only the samples taken 0 to 1 months after birth were considered. There was very good agreement between *T. cruzi* LAMP read by naked eye and fluorimeter (K=0.98) and between *T. cruzi* LAMP and qPCR (K=0.87). The *T. cruzi* LAMP kit could be used as a diagnostic tool for congenital Chagas disease cases in endemic and non-endemic countries.

1415

DEVELOPMENT OF A NOVEL BENZTHIAZOLE SCAFFOLD FOR CHAGAS DISEASE

Frederick S. Buckner[1], J. Robert Gillespie[1], Richard R. Tidwell[2], Donald A. Patrick[2], Pendem Nagendar[1], Andriy Buchynskyy[1], Zackary M. Herbst[1], Ranae M. Ranade[1], Michael H. Gelb[1]

[1]University of Washington, Seattle, WA, United States, [2]University of North Carolina, Chapel Hill, NC, United States

An estimated 7 million people, mostly in Latin America, are infected with *Trypanosoma cruzi,* the etiologic agent of Chagas disease. This chronic infection leads to cardiomyopathy or mega-syndromes of the intestines in ~30% of infected individuals. The existing anti-parasitic drugs (two nitroaromatic compounds) are associated with high rates of side-effects that greatly limit their use. A better tolerated and safe drug with potent anti-*Trypanosoma cruzi* activity is desperately needed to treat scores of infected people before they develop irreversible end-organ disease. Towards this end we are developing a novel compound series built around a benzthiazole core. The initial hit compound was

discovered in a high-throughput screen against the closely related parasite, *Trypanosoma brucei.* Subsequent testing against *T. cruzi* demonstrated an EC_{50} of 0.83 μM. Through iterative rounds of medicinal chemistry a lead compound (45DAP076) has been developed with an EC_{50} against *T. cruzi* of 0.12 μM. It has no cytotoxicity on mammalian cells at the highest concentration tested of 50 μM. When dosed to mice at 50 mg/kg by oral gavage, 45DAP076 achieved a peak plasma concentration of 23.2 μM with a robust area under the curve (AUC) of 13,217 min*μM. The compound was tested in an acute murine model of *Trypanosoma cruzi* infection with a 5 day treatment course beginning 7 days after the initial infection. 45DAP076 resulted in complete suppression of parasites but recrudescence occurred later (a result that was comparable to the clinical drug, benznidazole). The compound is currently undergoing testing in the more predictive chronic murine infection model. Analogs of 45DAP076 with further improved pharmacokinetic properties are also being tested. The near-term goal is to identify an optimized lead compound to advance for pre-clinical safety and toxicology testing.

DISCOVERY AND FINE EPITOPE MAPPING OF NOVEL SEROLOGY-BASED MARKERS FOR DIAGNOSIS OF CONGENITAL CHAGAS DISEASE USING HIGH-DENSITY PEPTIDE CHIPS

Leonel E. Bracco[1], Juan S. Mucci[1], Carlos A. Buscaglia[1], Oscar Campetella[1], Morten Nielsen[1], Valeria Tekiel[1], Guillermo Moscatelli[2], Samantha Moroni[2], Griselda Ballering[2], Jaime Altcheh[2], **Fernán Agüero**[1]

[1]Universidad Nacional de San Martín, San Martin, Argentina, [2]Hospital de Niños Ricardo Gutiérrez, Ciudad Autónoma de Buenos Aires, Argentina

Chagas Disease affects 6-8 million people in the Americas and at least 2 million women of fertile age are estimated to be chronically infected with *Trypanosoma cruzi*. Congenital infections represent a global problem, occurring both in endemic and non-endemic areas. Current diagnostic techniques for Congenital Chagas Disease (CCD) are cumbersome, have poor performance or require re-testing of newborns during the first year of age. New and improved diagnostics that can be deployed in primary health centers are urgently needed. Serology-based assays are preferred due to their low cost and simplicity, but currently suffer of poor performance in newborns due to the presence of confounding maternal antibodies. Furthermore, there is a very limited set of antigens characterized from congenital infections. Here we present a set of defined antigens and epitopes with an excellent potential for diagnosis of CCD. These were identified using a parallelized screening platform based on high-density peptide-arrays displaying >175,000 short peptides derived from 457 T. cruzi proteins. These arrays were screened with 2 pools of sera from 10 infected newborns, and with 2 paired pools of sera from their mothers. Each array was assayed with anti-human IgG (Cy3 labeled), and anti-human IgM (Cy5 labeled) secondary antibodies, and imaged in a fluorescence scanner. After data normalization, we reconstructed antibody-binding profiles for each protein and validated the assay by profiling known antigens. Comparative analysis of IgG reactivity between paired sera pools of newborns and their mothers allowed the identification of antigens with high IgG reactivity in infected newborns, and low or null reactivity in the paired samples from their mothers. We also identified candidate antigens with strong IgM reactivity in infected newborns. We prioritized 125 highly reactive peptides from the top 5% of IgG and IgM sets, and selected 48 short peptides for further validation and assessment of seroprevalence in standard ELISA format (currently underway). This study represents the largest screening so far for discovery of congenital markers of infection with *T. cruzi*.

1417

MODELING AND SIMULATIONS OF FEXINIDAZOLE TREATMENT REGIMEN FOR HUMAN AFRICAN *TRYPANOSOMIA BRUCEI GAMBIENSE* TRYPANOSOMIASIS (G-HAT) AND THEIR SUCCESSFUL CLINICAL APPLICATION IN ADULT AND CHILD PATIENTS

Virginie Gualano[1], Mathieu Felices[1], **Antoine Tarral**[2]

[1]PhinC Development, Massy, France, [2]Drugs for Neglected Diseases Initiative, Geneva, Switzerland

Fexinidazole is an oral formulation developed for the treatment of g-HAT. Fexinidazole is rapidly metabolized to sulfoxide (M1) and sulfone (M2). A population pharmacokinetic (POPPK) model which simultaneously models fexinidazole and its two metabolites in healthy volunteers (HV) was developed and then used to: (i) simulate dosing regimens in patients to obtain M2 plasma concentrations reaching the efficacious target, (ii) determine an optimized sparse PK dried blood sampling for patient studies, (iii) characterize the PK of fexinidazole, M1 and M2 in patients. POPPK modeling and simulations in HV were used to test several multiple dosing regimens. The identified dosing regimen was verified in HV and tested in three phase II/III clinical studies of stage 2 and early stage g-HAT (adults and children). A POPPK analysis of fexinidazole and metabolites in patients was performed based on sparse PK sampling. Based on the POPPK model simulations, the best tolerated regimen was once a day administration with food of 1800 mg for 4 days + 1200 mg for 6 days. The PK of fexinidazole and the two metabolites were characterized in adult and child patients. The expected level of efficacy in plasma (10μg/mL) was reached over the duration of treatment. The POPPK modeling and simulations based on fexinidazole and the two metabolites in HV predicted the PK parameters obtained in child and adult g-HAT patients. The resulting treatment regimen was well tolerated in children and adults, and led to the intended exposure.

COMPREHENSIVE INNATE IMMUNE PROFILING OF ZIKA CASES REVEALS A KEY ROLE OF MONOCYTES IN THE ACUTE PHASE OF INFECTION AND NO EFFECT OF PRIOR DENGUE VIRUS INFECTION ON THE INNATE IMMUNE RESPONSE

Daniela Michlmayr[1], Mayte Suaréz-Fariñas[2], Eun-young Kim[3], Adeeb Rahman[4], Seunghee Kim-Schulze[4], Guillermina Kuan[5], Angel Balmaseda[6], Steven M. Wolinsky[3], Andrew Kasarskis[2], Eva Harris[1]

[1]University of California Berkeley, Berkeley, CA, United States, [2]Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY, United States, [3]Division of Infectious Diseases, Feinberg School of Medicine, Northwestern University, Chicago, IL, United States, [4]Department of Oncological Sciences, Tisch Cancer Institute and the Immunology Institute, Icahn School of Medicine at Mount Sinai, New York, NY, United States, [5]Centro de Salud Sócrates Flores Vivas, Ministry of Health, Managua, Nicaragua, [6]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministry of Health, Managua, Nicaragua

Zika virus (ZIKV) is an emerging, mosquito-borne flavivirus responsible for the recent pandemic in the Americas. Much remains to be defined regarding the human immune response to ZIKV infection. To generate a comprehensive innate immune profile after ZIKV infection, we collected blood in PAXgene solution and plasma at acute (days 1-3 and days 4-6 post-onset of symptoms) and convalescent (days 14-16) time-points and peripheral blood mononuclear cells (PBMCs) at days 4-6 and convalescence from symptomatic RT-PCR-confirmed ZIKV-infected children in our long-term pediatric cohort study in Managua, Nicaragua. Patients were documented to be either previously exposed to the closely related dengue flavivirus (DENV) (n=42) or DENV-naïve (n=45). Innate immune responses were comprehensively profiled by CyTOF, Luminex cytokine/chemokine

assays, and RNA-seq. Interestingly, our results reveal that prior exposure to DENV does not impact the innate immune response and clinical symptoms. CyTOF results of all Zika cases showed that the frequency of CD14+ monocytes and CD14+CD16+ monocytes are expanded during the acute phase of infection. Luminex results revealed that levels of monocyte-attracting and pro-inflammatory cytokines, including CCL2, CCL3, CCL4, TNF-α, IFN-γ and IL-1α were elevated during acute ZIKV infection. Additionally, 4 distinct patterns of cytokine levels in serum were detected over time. Strikingly distinct transcriptomic and immunophenotyping signatures were associated with time-point, even between early and late acute phases. Within the significant transcriptomic signatures, we found that interferon signaling pathways and pattern recognition pathways were differentially regulated in acute and convalescent stages of infection. All data are being integrated for network modeling to generate global, unbiased maps of regulatory relationships and to uncover novel host-virus pathways and driver genes. To our knowledge, this study is the most comprehensive immune profiling and network analysis of the response to ZIKV infection in children to date and reveals no effect of prior DENV infection on innate immune responses.

RECENT PRIOR DENGUE VIRUS INFECTION PROTECTS AGAINST ZIKA IN A PEDIATRIC COHORT IN NICARAGUA

Aubree Gordon[1], Lionel Gresh[2], Sergio Ojeda[2], Leah C. Katzelnick[3], Nery Sanchez[2], Juan Carlos Mercado[4], Brenda Lopez[2], Douglas Elizondo[2], Raquel Burger-Calderon[3], Josefina Coloma[3], Guillermina Kuan[5], Angel Balmaseda[4], Eva Harris[3]

[1]Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, MI, United States, [2]Sustainable Sciences Institute, Managua, Nicaragua, [3]Division of Infectious Diseases & Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, [4]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministry of Health, Managua, Nicaragua, [5]Centro de Salud Sócrates Flores Vivas, Ministry of Health, Managua, Nicaragua

Zika virus (ZIKV) emerged in northeast Brazil in 2015 and spread rapidly across the Americas, including Nicaragua, where it caused an explosive epidemic in 2016. We analyzed the epidemiology of Zika in an ongoing, community-based cohort study of dengue that follows ~3,700 children aged 2-14 in Managua, Nicaragua, with well-characterized DENV immune histories. To identify Zika cases, RT-PCR was performed on acute blood and urine samples and serological assays were performed on paired acute and convalescent samples. Annual blood samples, collected every March/April, were used to serologically identify inapparent ZIKV infections. Multivariable Poisson regression was used to examine the relation between documented prior DENV exposure in the cohort and incidence of symptomatic and inapparent ZIKV infection. From January 2016 to February 2017, 545 Zika cases and 1226 ZIKV infections were identified in the cohort, for an overall incidence of 13.6 cases (95% confidence interval [CI]: 12.5, 14.8) and 37.2 infections (95% CI: 35.2, 39.3) per 100 person-years. Incidence of cases and infections was higher in females and in older children. Prior documented DENV infection was protective against developing Zika disease among those infected (Incidence Rate Ratio [IRR]: 0.60; 95% CI: 0.43-0.84) and in the total cohort population (IRR: 0.61; 95% CI: 0.47, 0.80) when adjusted for age, sex, and recent DENV infection (1-2 years before ZIKV infection). Recent DENV infection was protective against symptomatic ZIKV infection when adjusted for age and sex, but not when prior DENV immunity was included in the model. Prior or recent DENV infection did not affect the rate of ZIKV infection. These findings support that previous DENV infection protects individuals from symptomatic disease when they are infected with ZIKV.

Zika virus (ZIKV) transmission became a global public health emergency after the recent epidemic in Latin America and beyond revealed rare but dire manifestations of infection such as severe birth defects and Guillain-Barré syndrome. ZIKV's emergence in areas where other related flaviviruses such as dengue are endemic creates challenges in terms of accurately diagnosing infections, conducting reliable surveillance, but also in understanding the distinguishing aspects of the host immune response to ZIKV. Because vaccines represent a key strategy for prevention of infectious diseases and typically rely on a robust antibody responses, we sought to analyze the durable antibody responses in individuals infected by Zika as a first flavivirus infection. We observed complex populations of antibodies that bind to epitopes on intact virions, simpler epitopes on envelope protein monomers as well as envelope subdomains. Moreover, strong neutralizing antibody responses that minimally cross-react with dengue viruses were consistently detected. To better understand the molecular determinants of the neutralizing antibody response to ZIKV and to develop tools that could aid vaccine development, we isolated two potently neutralizing monoclonal antibodies (mAbs) from one primary ZIKV case and mapped key amino acid residues involved in mAb binding and neutralization by multiple complimentary methods including generation of neutralization escape mutants and alanine scanning mutagenesis. The mAbs recognize different epitopes on domain I and domain II of the viral envelope protein. Functionally, both mAbs were protective in a lethal mouse model of ZIKV infection. The antigenic sites on the virus defined by these mAbs appear to be common targets of the human response to ZIKV as their binding is consistently blocked by ZIKV- but not dengue-immune sera. This work provides new knowledge and tools that may be useful as diagnostic reagents or as therapeutics and will advance vaccine development.

1421

HOW CLOSE IS CLOSE? CHARACTERIZATION OF ZIKA AND DENGUE VIRUS CROSS-REACTIVE MEMORY B CELLS AND SERUM RESPONSES

Paulina Andrade[1], Ciara Gimblet-Ochieng[2], Faraz Modirian[1], Matthew Collins[2], Maritza Cárdenas[1], Magelda Montoya[1], Daniela Michlmayr[1], Guillermina Kuan[3], Angel Balmaseda[4], Josefina Coloma[1], Aravinda de Silva[2], Eva Harris[1]

[1]Division of Infectious Diseases & Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, [2]Division of Infectious Diseases, University of North Carolina, Chapel Hill, NC, United States, [3]Centro de Salud Sócrates Flores Vivas, Ministry of Health, Managua, Nicaragua, [4]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministry of Health, Managua, Nicaragua

Zika virus (ZIKV) recently spread rapidly throughout the Americas, co-circulating with dengue virus (DENV). The antigenic similarity of ZIKV and DENV raises important concerns regarding the effect of immunological cross-reactivity on protection and potential enhancement of ZIKV and DENV infections and vaccines. Here, we analyzed memory B cells (MBCs) from peripheral blood mononuclear cells (PBMCs) collected 2 weeks or ~7 months after RT-PCR-confirmed Zika cases from children who were DENV-naïve or had experienced 1 or >1 previous DENV infections (n=8-12/group) in a cohort study in Nicaragua. Analysis of activated MBCs using a

Multi-color FluoroSpot assay that enables measurement of B cell reactivity to DENV1-4 and ZIKV at a single-cell level showed that all ZIKV-infected patients mounted a highly type-specific response to ZIKV regardless of prior DENV infection, with 64% type-specific (TS) response in DENV-naïve and 45% TS response in previously DENV-infected groups ~7 months post-ZIKV infection. Previously DENV-infected groups displayed substantial DENV-ZIKV cross-reactivity 14 days post-ZIKV infection that decreased by ~7 months, while the TS proportion increased. The magnitude of DENV-ZIKV cross-reactive MBC responses decreased over time to a greater extent than TS responses. At ~7 months post-ZIKV infection, we characterized serum antibodies derived from plasma cells. In the great majority of both DENV-naive and previously DENV-infected individuals, depletion of cross-reactive antibodies did not substantially affect ZIKV neutralizing antibody titers, though these titers in a few patients were reduced, possibly due to shared neutralizing antibody epitopes between specific DENV serotypes and ZIKV. Prior infection by 1 versus >1 DENV before ZIKV infection did not differentially affect DENV-ZIKV cross-reactive responses, and DENV responses were lower than DENV-ZIKV responses at both 2 weeks and ~7 months post-ZIKV infection. This study improves our knowledge of B cell and serum antibody responses to closely related flaviviruses with implications for protection and pathogenesis of subsequent infections and vaccines.

1422

PROSPECTIVE INVESTIGATION OF A COMMUNITY-BASED COHORT OF PREGNANT WOMEN BEFORE AND DURING THE ZIKA EPIDEMIC IN NORTHEAST BRAZIL: SILENT TRANSMISSION AND INFANT OUTCOMES

Juan P. Aguilar[1], Federico Costa[1], Nivison Nery Jr.[1], Joseph Lim[2], Claudia Gambrah[2], Gielson Sacramento[3], Bruno Freitas[4], Joseane Bouzon[1], Jamary Oliveira-Filho[1], Haritha Adhikarla[2], Magelda Montoya[5], Elsio A. Wunder Jr[2], Athena Chin[5], Mitermayer Reis[3], Eva Harris[5], Albert Ko[2]

[1]Federal University of Bahia, Salvador, Brazil, [2]Yale School of Public Health, New Haven, CT, United States, [3]Oswaldo Cruz Foundation, Salvador, Brazil, [4]Hospital Geral Roberto Santos, Salvador, Brazil, [5]University of California, Berkeley, CA, United States

Little prospective information exists on Zika virus (ZIKV) transmission among pregnant women and clinical outcomes of their infants. We conducted a community-based prospective study among urban slum residents in Salvador, Brazil. We identified pregnant women from January 2015 to June 2016 and identified incident Zika seroconversions by analyzing biannually collected samples in the ZIKV35 monoclonal antibody Blockade of Binding (BoB) assay. We evaluated adverse outcomes by interviewing mothers and performing anthropometric measurements, neurologic (Hammersmith Exam, HINE), audiometric and ophthalmological evaluations and examinations with Bayley Scales of Infant Development III among infants. Among a cohort of 655 participants, 66 (10%) had at least one pregnancy during the study period. We completed follow-up for 46 (70%) of the 66 women, of whom Zika seroconversion occurred prior to, during and after the pregnancy in 25 (54%), 13 (28%), and 1 (2%), respectively. The earliest seroconversion event occurred between February and September 2013. Among the 48 pregnancies, 46 resulted in live births and two in spontaneous abortions. The 46 infants did not have evidence of microcephaly or congenital defects at birth. However, the 13 infants of mothers who seroconverted during pregnancy had increased risk of having low/borderline cognitive development scores (RR 5.08; 95% CI 1.05-24.43) than the 33 infants of mothers who did not seroconvert during pregnancy (4 [31%] of 13 vs. 2 [6%] of 33, respectively). Similarly infants of mothers who seroconverted during pregnancy had increased risk (RR 6.82: 1.54-30.17) of having altered behavior-observed audiometry findings than infants of mothers who did not seroconvert during pregnancy (5 [45%] of 11 vs. 2 [7%] of 30, respectively [missing data for 5 individuals]). These finding indicate that silent transmission of ZIKV occurred prior to the initial epidemic in early 2015. Furthermore, these findings suggest that a significant proportion of infants exposed *in utero* to ZIKV develop developmental deficiencies despite the absence of clinically evident neurological sequelae.

1423

EVIDENCE OF SHORT-TERM CROSS-IMMUNITY BETWEEN DENGUE AND ZIKA VIRUSES INFERRED USING LONGITUDINAL SEROLOGICAL AND SURVEILLANCE DATA FROM FIJI, 2013-2017

Alasdair Henderson[1], Mike Kama[2], Van-Mai Cao-Lormeau[3], Colleen Lau[4], John Edmunds[1], Conall Watson[1], Adam Kucharski[1]

[1]Centre for the Mathematical Modelling of Infectious Diseases, London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Communicable Disease Control, Ministry of Health, Suva, Fiji, [3]Institut Louis Malardé, Tahiti, French Polynesia, [4]University of Queensland, Brisbane, Australia

The Zika (ZIKV) and dengue (DENV) viruses are two closely related flaviviruses that share the same primary vector, the *Aedes* genus of mosquitos. Given the antigenic similarity between these viruses it has been hypothesised that DENV antibodies may cross-react with ZIKV. To investigate the role of DENV cross-protection on ZIKV dynamics during overlapping outbreaks, we combined a transmission dynamic model with serological and surveillance data from Central Division, Fiji. Longitudinal population representative seroepidemiological data were available from participants sampled in 2013, 2015 and 2017. In addition, surveillance data were available from a major DENV-3 outbreak in 2013/14, and ZIKV case reports from 2015 and 2016. Using a Bayesian approach, we fitted a transmission dynamic model with a seasonally varying transmission to these data to estimate the probability that DENV would confer transient immunity against ZIKV infection, as well as the length of this immunity. We found evidence that DENV infections generated strong, short-term, immunity against ZIKV infection and that this relationship could explain the multi-wave transmission dynamics of ZIKV in Fiji. We found evidence that the virus was introduced in early 2013 and persisted for several years with minor outbreaks in consecutive years, with dynamics determined by seasonality of transmission, pre-existing immunity and cross-immunity following DENV infection. Our analysis provides ecological evidence of interaction between ZIKV and DENV and shows the value of linking multiple data sources to reconstruct ZIKV dynamics. The availability of detailed case and serology data in an island outbreak setting – combined with mathematical models – presented a unique opportunity to gain crucial insights into these infections. Seasonal variation in transmission, combined with other co-circulating flaviviruses, means the timing of ZIKV introduction can have a major impact on outbreak transmission dynamics.

1424

MAPPING REACTIVITY TO ZIKA VIRUS IN MEMORY B CELLS FOLLOWING DISTINCT ANTECEDENT FLAVIVIRUS EXPOSURES

Huy A. Tu[1], Matthew H. Collins[2], Guei-Jiun Liou[2], Ramesh S. Jadi[2], Aravinda M. De Silva[2], **Sean A. Diehl**[1]

[1]University of Vermont, Burlington, VT, United States, [2]University of North Carolina, Chapel Hill, NC, United States

Flaviviruses such as dengue (DENV) and Zika viruses (ZIKV) encompass increasingly overlapping circulation areas. Serologic cross-reactivity amongst flaviviruses is a potential result of new flaviviruses emerging into an area endemic for other flaviviruses. This phenomenon can lead to diagnostic difficulties, enhancement of disease, or potentially broader protective, natural immunity. However, there is only a limited understanding of the evolution of the human antibody response at the clonal level to sequential flavivirus infections, particularly those involving different serogroups. To address this problem, we recruited travelers exposed to ZIKV virus and characterized neutralizing antibody titers to

DENV and ZIKV in their plasma to assess flavivirus exposure history. Based on serology and self-reported travel and medical histories, we classified subjects as having either ZIKV as a primary flavivirus infection or ZIKV as a post-primary flavivirus infection (typically meaning ZIKV infection in a DENV-immune subject). To assess the extent to which primary or post-primary ZIKV infection led to distinct memory B cell (MBC) repertoires, we immortalized these cells from peripheral blood and assessed reactivity to ZIKV and different DENV serotypes. The frequency of ZIKV-binding MBCs was higher in primary ZIKV subjects (0.9-1.2% of immortalized MBCs) compared to post-primary ZIKV subjects (0.1-0.17%). Strikingly, we also found that regardless of exposure history, ZIKV infection induced a dominant ZIKV-specific response (81-96%) with limited cross-reactivity to DENV (4-19%). Further studies are aimed at understanding the clonality of primary or post-primary ZIKV responses with regard to VH/VL gene usage, CDR3 length, and level of somatic hypermutation, and whether patterns change over time.

1425

HIGH RESOLUTION MAPPING OF GLOBAL CHILD MORTALITY

Roy Burstein[1], Nat Henry[1], Michael Collison[1], Chloe Shields[1], Aaron Osgood-Zimmerman[1], Annie Browne[2], Joshua Longbottom[3], Simon Hay[1]

[1]University of Washington / IHME, Seattle, WA, United States, [2]University of Oxford, Oxford, United Kingdom, [3]Lancaster University, Lancaster, United Kingdom

We present findings from an effort to produce high resolution maps of mortality rates and death counts for neonates, infants, and children under-5 across 120 low and middle income countries. Some 4.8 million, or 97% of all global child deaths, occurred within these countries in 2016. We compiled and geo-referenced data on nearly 28 million child deaths across nearly two decades, from 1998-2016. Sources include complete and summary birth histories from sample surveys and censuses, in combination with vital registration data. This is a methodological first. We developed new methods to account for biases in these various data sources across space and time, including systematic under-reporting in vital registration data. We also developed a new geostatistical model which accounts for residual spatiotemporal correlation across age groups. Our findings highlight great improvements since 2000, yet entrenched subnational inequalities. We focus specifically on subnational heterogeneity in the proportion of child deaths in different age groups under 5. In general, progress in reducing neonatal mortality has been slower than in older children, but to greatly varying degrees even within countries. Reducing neonatal mortality will require a different set of interventions than those which have successfully reduced mortality in older children. Finally, in addition maps of mortality rates, we also provide estimates of numbers of child deaths by 5x5 pixel and by subnational units (districts and provinces). Such maps will arm policymakers with information critical in targeting public health interventions to children at highest risk.

Children die disproportionately in Africa and South Asia. The CHAMPS Network aims to improve understanding about causes of child mortality through longitudinal surveillance and etiologic investigation of child deaths and stillbirths by combining post-mortem minimally invasive tissue sampling (MITS), molecular, microbiologic, and histopathologic testing, clinical records, and verbal autopsy. From 635 cases with MITS as of 6/6/2018, we analyzed 270 (43%) cases with causes of death (COD) assigned by CHAMPS expert panels using standardized approaches. Cases were from South Africa (162, 60%), Mozambique (46, 17%), Kenya (46, 17%), Mali (11, 4%), and Bangladesh (5, 2%); 243 (90%) died in a health facility. Among 138 neonates, 40 died on day zero, and 60 within 6 days. Most common neonatal underlying COD were preterm birth complications (35), neonatal encephalopathy (13), maternal hypertension (12), congenital birth defects (13), and sepsis (8). Main factors in stillbirths (n=31) were maternal hypertension (7), placental hemorrhage (4), and labor and delivery complications (4). Main underlying causes in children 1-59 mos old (n=101) were lower respiratory infections (16), malnutrition (12), congenital birth defects (12), neonatal preterm birth complications (11), and diarrheal diseases (9). Pathogens contributed to death in 58% of cases; 31% had multiple causal pathogens. Leading pathogens were *Klebsiella pneumoniae*, *Acinetobacter baumannii*, *Streptococcus pneumoniae*, *E. coli*, cytomegalovirus, *Staphylococcus aureus*, respiratory syncytial virus; 42% had no causal pathogen. Among 49 preterm cases, 36 (73%) had >1 pathogen in the causal chain. Fatal injuries (burns, transport, poisoning) and noncommunicable conditions (sickle cell, cancer) were also observed. Panelists deemed 67% of all cases to be preventable. These early data highlight the importance of understanding multicausal patterns, maternal factors, and interplay between infectious and chronic conditions in child deaths. As data accrue with more community deaths represented, CHAMPS will produce new actionable knowledge to reduce child and perinatal mortality.

Approximately 5 million children per year die before their fifth birthday, with disproportionate mortality in sub-Saharan Africa and South Asia.

Vital registration systems capture only a fraction of these deaths, often with low specificity for causes of death. The Child Health and Mortality Prevention Surveillance (CHAMPS) Network was established to define the causes of under-5 mortality and stillbirth using population-based surveillance and novel diagnostic approaches, including minimally invasive tissue sampling (MITS). We describe initial results from rapid notification systems and consent for the MITS procedure. Surveillance for under-5 deaths and stillbirths began in one site in December 2016, with other sites beginning over the course of 2017. As of February, 2018, 5 sites (Manhiça, Mozambique; Soweto, South Africa; Bamako, Mali; Kisumu, Kenya; Baliakandi, Bangladesh) were actively collecting mortality surveillance and laboratory data. Cumulatively through 15 Feb 2018, CHAMPS had received 2634 unique notifications (68% from health facilities; 16% community reporter or health worker; 5% demographic surveillance staff; 11% other source). Screening determined 1074 cases (42% of unique notifications) to be eligible for inclusion. Most eligible deaths (80%) occurred in health facilities, with 50% from a large tertiary hospital in Soweto. Of all eligible deaths, 707 (66%) were notified within 24 hours of death (23% over 24 hours; 11% missing), with this proportion increasing from 47% in Dec 2016 to 75% in January, 2018. A total of 687 families were approached for consent for the MITS procedure. Of these, 75% provided consent (range by site:58% to 96%). A total of 500 MITS procedures had been conducted by February 15, 2018. These data suggest that it is feasible to obtain notifications of deaths in <24 hours in diverse high-under-5 mortality settings and obtain post-mortem tissue samples in a substantial proportion which over time will provide opportunities to provide more specificity for mortality burden estimates.

1428

MATERNAL FACTORS ASSOCIATED WITH PERINATAL MORTALITY SHOULD BE EASILY IDENTIFIED DURING ANTENATAL VISITS. THE 1000 *DAYS* COHORT STUDY IN RURAL NIGER

Anne Thomas[1], Deo Sibongwere[2], Maguy Daures[1], Benjamin Séri[3], Nafissa Dan-Bouzoua[4], Moumouni Kinda[4], Claire Levy-Marchal[4], Augustin Augier[4], Valérie Briand[1], Susan Shepherd[4], **Renaud Becquet**[1]

[1]University of Bordeaux, Inserm, Bordeaux Population Health Research Center, team IDLIC, UMR 1219, Bordeaux, France, [2]Alliance for International Medical Action (ALIMA)/Bien Être de la Femme et de l'Enfant au Niger (BEFEN), Niamey, Niger, [3]PACCI research programme, University Hospital of Treichville, Abidjan, Côte D'Ivoire, [4]Alliance for International Medical Action (ALIMA), Dakar, Senegal

Epidemiologic data on perinatal mortality, defined as stillbirth or neonatal death within 7 days of birth, is scarce in African rural areas. From April 2015-June 2016, a cohort study was implemented in 5 health facilities in rural Niger (Zinder region, Mirriah department), enrolling all pregnant women presenting for a first antenatal care (ANC) visit. They received a standard ANC package defined by the Ministry of Health. We used a multivariate generalized linear mixed model to examine factors associated with perinatal mortality, including study site as a random effect. A complication score was created based on the following six danger signs identified during ANC: age ≤18 years or ≥35 years, primiparity, multiple gestation, severe anemia (<7g/dL), positive malaria rapid diagnostic test (RDT), pre-eclampsia (high blood pressure and proteinuria). Of 1,745 pregnant women included in the cohort study, 1,679 women gave birth (4 maternal deaths, 12 abortions, and 50 unknown pregnancy outcomes). In total, 84 (5.0%) births were considered as perinatal deaths and 1,595 children were alive at 7 days of life. Perinatal mortality was associated with fewer than 4 ANC visits (aOR 1.71; 95%CI 1.01–2.88; p=0.05), primiparity (aOR 2.18; 95%CI 1.32–3.61; p<0.01), positive malaria RDT during pregnancy (aOR 2.55; 95%CI 1.29–5.06; p<0.01), severe anaemia during pregnancy (aOR 3.01; 95%CI 1.06–8.52; p=0.04). Overall, 19%, 10% and 1% of women presented with one, two and three danger signs, respectively. Perinatal mortality in babies born to women without danger signs was 3.5% (41/1,171) compared to 8.5% (43/508) among those born to women with at least one danger sign (aOR 2.45, 95%CI 1.58-3.81). We found no association between the occurrence of danger signs and place of delivery: only 37.5% (449/1,171) of women without danger signs and 37.4% (190/508) of those with at least one danger sign gave birth in health facilities (p=0.97). Perinatal mortality was associated with maternal risk factors easily identified during ANC, however reducing perinatal deaths in this at-risk group would require delivery by more highly skilled medical personnel.

1429

PREDICTING IN-HOSPITAL MORTALITY USING ROUTINE DATA TO GUIDE DECISION MAKING FOR ESSENTIAL NEONATAL CARE

Martin J. Aluvaala[1], Gary Collins[2], James Berkley[3], Mike English[4]

[1]University of Nairobi, Nairobi, Kenya, [2]University of Oxford, Oxford, United Kingdom, [3]KEMRI-Wellcome Trust, Kilifi, Kenya, [4]KEMRI-Wellcome Trust, Nairobi, Kenya

More than 98% of neonatal deaths occur in low and middle-income countries (LMICs) and hospitals in these regions are expected to play a key role toward achievement of Sustainable Development Goal 3.2 "reduce neonatal mortality to 12 per 1000 live births and below". To deliver quality care in LMICs, rationally designed hospital services are required. The study aimed to generate better neonatal prognostic data and use it to develop locally relevant prognostic models and explore their potential to support decision making for essential neonatal care. Using the largest neonatal unit routine data set in Kenya (n=11,850), logistic regression was applied to (1) develop a model to predict in-hospital mortality using five treatments derived from essential neonatal care prescribed at admission, (2) develop an alternative model using symptoms and signs of severe illness documented at admission. Calibration plots were used to measure model discrimination and calibration. Decision curve analysis was used to compare the potential clinical utility of the models using the net benefit. The Neonatal Essential Treatment Score (NETS) and the Score for Essential Symptoms and Signs (SENSS) have good discrimination (each with c-statistic of 0.89) but the SENSS model is better calibrated (calibration slope 0.90 compared to 0.76 for NETS). Net benefit is observed over a wider range of predicted probabilities for SENSS (0 to greater than 80%) in comparison to NETS (0 to 80%) due to the superior calibration of SENSS. The NETS model would result in a higher number of patients classified at high risk of inpatient death across the range of predicted probabilities. Both models can be presented as simple score charts for use by clinicians at the point of care. NETS and SENSS are based on predictors available in basic routine data and may support clinical decisions such as referrals and aid in the organisation of different levels of neonatal hospital care within a region. The performance of these models may be evaluated further by geographical external validation using data from similar neonatal units followed by impact assessment in a cluster randomised controlled trial.

of Virginia, Charlottesville, VA, United States, [6]Christian Medical College, Vellore, India, [7]Haydom Lutheran Hospital, Haydom, United Republic of Tanzania, [8]Johns Hopkins University, Baltimore, MD, United States, [9]Universidade Federal do Ceara, Fortaleza, Brazil, [10]Armed Forces Research Unit, Kathmandu, Nepal, [11]Kathmandu Medical College, Kathmandu, Nepal, [12]Aga Khan University, Karachi, Pakistan, [13]University of Venda, Thohoyandou, South Africa

Poor growth in early childhood is considered to have both short- and long-term consequences on health and development in low-income settings. The goal of this analysis was to identify factors (illness, pathogen burden, dietary intake, gut function, micronutrient status, and socioeconomic factors) in the first two years of life that are associated with growth outcomes at five years of age. The data are from seven sites in the MAL-ED cohort study, including 1,004 children enrolled from 0-17 days after birth and followed until five years of age. Gut function biomarkers were related to size at five years. Mean L:M Z-scores during the first 2 years of life were negatively associated with all of the growth outcome measures in this study (HAZ: -0.12 (95% CI -0.20, -0.04); WAZ: -0.17 (95% CI -0.27, -0.07); BMIZ: (-0.12 (95% CI -0.24, 0.0)). Myeloperoxidase was negatively associated with the weight measures (WAZ: -0.54 (95% CI -0.82, -0.26) and BMIZ: -0.59 (95% CI -0.91, -0.27)), but not with HAZ; whereas alpha-1-antitrypsin had a negative association with HAZ (-0.26 (95% CI -0.50, -0.02), but not with the weight measures. Indicators of iron status were also related to size at five years. Transferrin receptor was positively related to HAZ (0.21 (95% CI 0.09, 0.33)) and WAZ (0.23 (95% CI 0.09, 0.37)) at five years. Haemoglobin was positively related to HAZ (0.07 (95% CI 0.01, 0.13)), and ferritin was negatively related to HAZ (-0.08 (95% CI -0.12, -0.04)). Among the infection/illness factors that we tested, bacterial density in stool was negatively associated with HAZ (-0.04 HAZ per 10% increase in bacteria positive samples (95% CI -0.08, 0.00)), but illness symptoms did not have an effect on size at five years. Size at enrolment and socioeconomic status were both positively related to all of the growth outcomes. Longitudinal markers of environmental enteric dysfunction (EED) and bacterial density are associated with poor growth outcomes at five years of age. Iron markers are also related to growth outcomes. Environmental interventions to reduce bacterial burdens and EED, including vaccines where appropriate, may improve long-term growth in low-income settings.

1431

HOUSEHOLD-LEVEL FACTORS ASSOCIATED WITH CHILDHOOD GROWTH IN BANGLADESH: AN ANALYSIS OF THE MULTIPLE INDICATOR CLUSTER SURVEY, 2012-2013

J. Johanna Sanchez[1], Tahmeed Ahmed[2], Mustafa Mahfuz[2], Peter Sly[1], Kurt Z. Long[3]

[1]University of Queensland, Brisbane, Australia, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]Swiss Tropical and Public Health Institute, Basel, Switzerland

Growth impairment in children continues to be a leading global health concern, despite improvement in recent decades. An understanding of factors associated with growth could contribute to public health efforts. The study examined the household-level factors associated with children growth using data from the Multiple Indicator Cluster Survey (MICS) in Bangladesh. A total of 7851 children 0-24 months of age were included in the analysis. A linear mixed model analysis with household as a random effect was used to test for the effect of different household factors independently associated with height-for-age z-score (HAZ). Interactions were also tested to understand the relationships between factors. Significant factors were included in a stepwise regression to identify the final combination of factors influencing the outcome. Children in our sample were on average 1.45 standard deviations shorter than the WHO reference standard. Age of the child was also negatively associated with the outcome, with HAZ scores decreasing with increasing child age. Maternal education and presence of a refrigerator in the household were positively associated with HAZ, while male sex, unimproved toilet facilities, and shared toilet facilities had a negative effect on HAZ. In addition, maternal education was found to reduce the negative association of unimproved toilet facilities and shared toilet facility with HAZ. The results indicate that growth impairment continues to be a public health concern in Bangladesh, and that child growth, as measured by HAZ, is associated with several household-level factors. Maternal factors were also important factors in modifying the effect of some of these factors. Interventions should therefore not only target these factors but also consider the relationships that exist between them.

1432

VECTOR BIONOMICS AND TRANSMISSION INTENSITIES OF MALARIA VECTORS ON BIOKO ISLAND OVER 14 YEARS OF INTEGRATED VECTOR CONTROL

Godwin Fuseini[1], Wonder Philip Phiri[1], Guillermo Garcia[2], Raul Nguema Ncogo[1], Liberato Motobe[1], Carlos Cortes Falla[1], Christopher Schwabe[2]

[1]Medical Care Development International, Malabo, Equatorial Guinea, [2]Medical Care Development International, Silver Spring, MD, United States

Entomological surveillance has been an integral part of the Bioko Island Malaria Control Project (BIMCP) since the implementation of the project in 2004. Systematic vector surveillance over the years continued to inform and guide the vector control interventions in attaining remarkable outcomes. This study analyses the trend in the vector bionomics and transmission intensities of the local vectors since the inception of the BIMCP. The feeding and resting behaviors, as well as the compositions of the local vectors were monitored using window traps, CDC light traps, and human landing catches. Trends in vector densities, sporozoite rates, and the entomological inoculation rates (EIR) were determined. Phenotypic resistance profile of the malaria vectors as well as target-site resistance and metabolic resistance patterns were also monitored. *An gambiae s.s*, (S and M forms) constituted 45% of the local vectors at baseline with *An funestus* 45% and *An melas* 10%. However after two years of IRS *An. funestus s.l.* was eliminated. In 2009, *An gambiae s.s. S*. was also eliminated and as of 2017, *An gambiae s.s. M* (*An. coluzzii)* (70%) and *An. melas* (30%) remained the main vectors on the Island. Biting rates have reduced from an average of 35 bites per person per night in 2009 to an average of 8 bites per person per night in 2017. Vectors biting behavior shifted to more of outdoor biting between 2004 and 2014. The EIR has dropped from 1,214 infective bites person per annum at baseline to 13 infective bites per person per annum in 2017. The frequency of *kdr-w* has increased to over 85% in the vector population in addition to the presence of P450s pyrethroid metabolizers. However, AChE mutations have not been detected. The planning, implementation, monitoring and evaluation of vector control interventions rely on the knowledge of the local vectors for effective programs. Changes in vector behaviors and transmission intensities are essential in directing vector control interventions and measuring the impacts of such interventions.

1433

ANNUAL INDOOR AND OUTDOOR ENTOMOLOGICAL INOCULATION RATES IN *ANOPHELES GAMBIAE, AN. COLUZZII*, AND *AN. ARABIENSIS* ACROSS FIVE ECOZONES OF NIGERIA

Vector control is the primary transmission reduction strategy against malaria in Nigeria. The entomological inoculation rate (EIR) measures exposure to infective bites received by an individual during a specific time interval. Investigations were carried out in all six sentinel sites where *Plasmodium falciparum* is transmitted mainly by *Anopheles gambiae, An. coluzzii* and *An. arabiensis*. Entomological surveillance occurred monthly over one year (Jan-Dec 2017) across five ecozones in Nigeria. Malaria vectors were collected using human-baited CDC light traps (4 houses/site) both indoor and outdoor, and pyrethrum spray catches indoors (32 houses/site). The vectors were identified morphologically and the sibling species were identified using PCR assays. *P. falciparum s*porozoite rates were determined by ELISA. EIRs were calculated using standard methods. Indoor EIR values were recorded for *An. gambiae* with a range from 1.2 infective bites per person per year(ib/p/yr) in the Sahel-savannah (Sokoto) to 23.9 ib/p/yr recorded in the mangrove swamp/rainforest (Akwa Ibom). Indoor EIR values for *An. coluzzii* ranged from 0.9 ib/p/yr in the forest (Oyo) to 11.4 Ib/p/yr in the rainforest (Ebonyi). However, higher indoor EIR were recorded among *An. coluzzii* only in the rainforest, though this did not vary significantly from *An. gambiae* (p=0.059). For *An. arabiensis,* the highest indoor EIR of 4.7 Ib/p/yr was recorded in the Sahel-savannah. For outdoor EIR, *An. gambiae* remained the dominant malaria vector with the highest EIR of 19.2 ib/p/yr recorded in the Sahel-savannah and the lowest EIR of 0.8 Ib/p/yr recorded in the forest. For *An. coluzzii,* outdoor EIR ranged from 0.1 Ib/p/yr in the mangrove to 0.7 ib/p/yr in the Guinea-savannah. Outdoor EIR *for An. arabiensis* ranged from 2.9 ib/p/yr in the Guinea-savannah and 0.2 ib/p/yr in the forest and mangrove swamp/rainforest areas. The high outdoor EIR for *An. gambiae* in the Sahel-savannah could be a factor in persistently high parasite prevalence in the Sahel region despite LLIN coverage of >80%. New tools targeting outdoor transmission may be required to achieve national malaria control targets.

1434

REPLACEMENT OF INDOOR RESIDUAL SPRAYING ''IRS" BY LONG LASTING INSECTICIDAL NETS ''LLINS" AND SEASONAL MALARIA CHEMOPREVENTION ''SMC" ASSOCIATED WITH CHANGES OF KEY ENTOMOLOGICAL INDICATORS OF MALARIA TRANSMISSION IN SOUTHERN MALI

Arthur Sovi[1], Chitan Keita[1], Youssouf Sinaba[1], Abdourhamane Dicko[2], Dereje Dengela[3], Elie Bankineza[1], Jules Mihigo[4], Kristen George[5], Christen Fornadel[5], Laura Norris[5], Richard Oxborough[6]

[1]U.S. Agency for International Development PMI AIRS project, Abt Associates, Bamako, Mali, [2]Programme National de Lutte Contre le Paludisme, Bamako, Mali, [3]U.S. Agency for International Development PMI AIRS project, Abt Associates, Bethesda, MD, United States, [4]US President's Malaria Initiative, US Agency for International Development, Bamako, Mali, [5]US President's Malaria Initiative, US Agency for International Development, Washington, DC, United States, [6]U.S. Agency for International Development PMI AIRS project, Abt Associates, London, United Kingdom

Malaria vector control by IRS was implemented in Southern Mali in 2013-2014 with bendiocarb and in 2015-2016 with Actellic 300CS with support from PMI/USAID. IRS was relocated to Mopti Region in 2017 given particularly high malaria incidence at health facilities. LLINs and SMC were provided to populations in former IRS sites, as part of national policy. Entomological monitoring was conducted from June to December in 3 districts (2 sprayed: Koulikoro & Baroueli and 1 adjacent unsprayed: Kati) in 2016 and 2017, covering the last year of IRS and 1st year of IRS relocation. Monthly collections of mosquitoes were performed by pyrethrum spray catch in 20 houses/site to determine indoor resting densities and by human landing catches in 8 houses/site to determine human biting rates (HBR), species composition and entomological inoculation rate (EIR). Molecular analysis was conducted to determine sporozoite rates (SR) and species identification. In sites where IRS was withdrawn, the vector density doubled after IRS cessation (mean of 6.0 *An. gambiae*/house in 2017 versus 3.0 in 2016), while in the control site there was a decrease (5.4 *An. gambiae*/house in 2017 versus 12.1 in 2016). Similarly, in sites where IRS was withdrawn, HBR was extremely high at 28.7 bites/human/night (b/h/n) in 2017 compared to 2016 (6.1 b/h/n); a 4.7 fold increase after IRS cessation. In the control site, there was a lower magnitude increase in HBR (36.5 b/h/n in 2017 versus 22.1 in 2016, 0.6 fold increase). *An. coluzzii* was the major vector (95%). In IRS sites, the SR was similar for both years at 0.8% (95%CI: 0.2-1.5) in 2017 versus 1.3% (95%CI: 0.2-2.5) in 2016; p=0.42. The trend was the same for the control site at 0.8% (95%CI: 0-1.7) in 2017 versus 0.4% (95% CI: 0-1.2) in 2016, p=0.5. Following IRS relocation, EIR in IRS areas increased two fold to 15.37 infectious bites/human/5months in 2017 versus 7.05 ib/h/5months in 2016. In the control site, there was a threefold decrease (6.21 ib/h/5months in 2017 versus 18.6 ib/h/5months in 2016). Overall, following IRS relocation there was no significant increase in SR, but the biting rate increased substantially, resulting in a doubling of EIR.

1435

THE BEHAVIORAL AND PHYSIOLOGICAL ADAPTATIONS OF MALARIAL MOSQUITOES SINCE 2000 AND CONSEQUENCES FOR PUBLIC HEALTH IMPACT IN AFRICA

Ellie Sherrard-Smith[1], Janetta Skarp[1], Andrew Beale[2], Christen Fornadel[3], Laura Norris[3], Thomas S. Churcher[1]

[1]Imperial College London, London, United Kingdom, [2]University of Surrey, Surrey, United Kingdom, [3]U.S. President's Malaria Initiative, U.S. Agency for International Development, Washington, DC, United States

The anti-malarial efficacy of key vector control interventions - long-lasting insecticidal nets (LLINs) and indoor residual spraying (IRS) - are reliant on technologies that interrupt human biting by exploiting the night time, indoor feeding patterns of primary African vectors. There is a potential public health impact due to increasing physiological resistance, enabling mosquitoes to overcome toxic insecticidal effects, or behavioural adaptations that facilitate avoidance of toxic exposures. The impact of physiological resistance on the efficacy of nets and IRS has been quantified using WHO discriminatory dose bioassay tests and experimental hut studies. A systematic review of mosquito and human behaviour and an established transmission model for malaria are then used to estimate i) a public health impact of changes in exposure risk; ii) the consequential impact of both resistance mechanisms together, and; iii) the residual transmission across Africa and consequences for the efficacy of indoor vector control. There are few studies on human indoor or sleeping behaviours which is crucial for evaluating indoor vector interventions. However, temporal data suggest a transition to increased outdoor biting for key malaria-transmitting mosquitoes. Physiological and behavioural resistance were not found to be associated suggesting these may be independent mechanisms assisting mosquito survival in the presence of insecticides. As mosquito communities transition to become increasingly able to avoid deleterious impacts of indoor interventions, the burden of residual transmission increases. We find an association between places with more outdoor biting and a reduced efficacy of indoor vector control. This is the first study to quantify both physiological and behavioural resistance mechanisms of mosquitoes and extrapolate the public health impact. Novel interventions targeting the control of vectors outdoors will be critical for malaria control going forward.

1436

SCREENING AND FIELD PERFORMANCE OF POWDER-FORMULATED INSECTICIDES ON EAVE TUBE INSERTS AGAINST PYRETHROID RESISTANT *ANOPHELES GAMBIAE*: AN INVESTIGATION INTO ACTIVES PRIOR TO A RANDOMIZED CONTROLLED TRIAL IN CÔTE D'IVOIRE

Welbeck A. Oumbouke[1], Innocent T. Zran[2], Antoine M. Barreaux[3], Alphonsine Koffi[2], Eleanore D. Sternberg[3], Matthew B. Thomas[3], Raphael N'Guessan[1]

[1]London School of Hygiene & Tropical Medicine/ Institut Pierre Richet, Bouake, Côte D'Ivoire, [2]Institut Pierre Richet, Bouake, Côte D'Ivoire, [3]The Pennsylvania State University, Pennsylvania, PA, United States

Electrostatic coating is a new way of delivering insecticides to mosquitoes visiting homes for blood source. Although previous tests demonstrated the resistance breaking potential of this chemical application method, studies screening and investigating the residual efficacy of broader range insecticides are necessary. Eleven insecticide powder formulations belonging to seven insecticide classes were initially screened for residual activity over 4 weeks against pyrethroid resistant *Anopheles gambiae s.l.*. Tests were performed using the eave tube assay. With the best performing insecticide we monitored the persistence over 12 months and explored the actual contact time lethal to mosquitoes, using a range of transient exposure time (5s, 30s, 1min up to 2 min) in the tube assays in laboratory. The mortality data were calibrated against overnight release recapture data from enclosure around experimental huts incorporating treated inserts. Natural recruitment rate of mosquitoes to the tube without insecticide treatment was assessed using fluorescent dust particles. Although most insecticides assayed during the initial screening induced significant mortality (45-100%) of pyrethroid resistant *An. gambiae s.l.* during the first two weeks, only 10% beta-cyfluthrin retained high residual efficacy, killing 100% of An. gambiae during the first month and >80% over 8 subsequent months. Transient exposure for 5 seconds of mosquitoes to 10% beta-cyfluthrin produced 56% mortality, with an increase to 98% when contact time was extended to 2min (P = 0.001). In the experimental huts with enclosure, mortality of *An. gambiae* with 10% beta-cyfluthrin treated inserts was 55% compared to similar rate (44%) of mosquitoes that contacted the inserts treated with fluorescent dusts. This indicates that all host-seeking female mosquitoes that contacted beta-cyfluthrin treated inserts during host-seeking were killed.Beta-cyfluthrin showed great promise for providing prolonged control of pyrethroid resistant *An. gambiae s.l.* and has potential to be deployed year-round for the eave tube technology.

1437

IMPACT OF THE DUPLICATED P450 GENE, CYP6P9A AND CYP6P9B ON THE EFFECTIVENESS OF VARIOUS BED NETS AGAINST *ANOPHELES FUNES*TUS, A MAJOR MALARIA VECTOR IN AFRICA

Benjamin Menze, Murielle Wondji, Micareme Tchoupo, Charles Wondji

LSTM Unit at Centre for research in infectious diseases (CRID), Yaounde, Cameroon

Insecticide-based interventions are reducing malaria burden. Unfortunately, growing insecticide resistance in malaria vectors is threatening these successes. However, the extent of the impact of this resistance notably, metabolic resistance on the effectiveness of insecticide-based interventions such as long lasting Insecticidal Nets (LLINs) remains unclear. Taking advantage of the recent detection of the first DNA-based molecular marker for metabolic resistance in the Cytochrome P450 genes (CYP6P9a and CYP6P9b), we used an experimental hut study in Cameroon to assess the impact of metabolic resistance driven by the duplicated P450 genes, CYP6P9a and CYP6P9b on the performance of five LLINs (Olyset, Olyset Plus, PermaNet 2.0 and PermaNet 3.0). After an experimental hut trial on the field and cone assay in the laboratory, mosquitoes were genotyped for the CYP6P9a and CYP6P9b to assess its impact. A reduced efficacy of LLINs was observed against the pyrethroid resistant fumoz-fang lab strain (*An. funestus*) with significantly lower mortality rates (<31.4%; P<0.0001 for PermaNet 2.0 and <56.7%; P<0.0001 for Olyset) although PBO-based nets had the highest mortality. However, the blood feeding rate is significantly reduced in the LLINs (10.2% to 6.8%, p<0.0001) vs control (28.7%). A strong association was observed between the presence of the CYP6P9a and the ability to survive in the presence of the bed nets: PermaNet 2.0 (OR= 15.5; p<0.0001), PermaNet 3.0 (OR= 11.6; p<0.0001), Olyset (OR= 7.7; p<0.0001), Olyset Plus (OR= 2.5; p<0.0001). The same association was observed between the CYP6P9a and the ability to blood feed in the presence of bed nets: Olyset (OR= 2.3; p<0.0001), PermaNet 3.0 (OR= 4.5; p<0.0001). The loss of efficacy of LLINs against pyrethroid resistant *An. funestus* and the increased ability to survive and blood feed of CYP6P9a resistant mosquitoes highlight the impact of resistance on effectiveness of insecticide-based interventions.

MALARIA VECTOR SURVEILLANCE - CAN VECTOR DATA GUIDE COUNTRY POLICY AND PROGRAMMATIC MALARIA CONTROL DECISIONS?

Tom Burkot[1], Tanya L. Russell[1], Min Myo[2], Abraham Mnzava[3], Effie Espino[4], Robert Farlow[5]

[1]Australian Institute of Tropical Health and Medicine, Cairns, Australia, [2]Asian Pacific Malaria Eliminaton Network, Singapore, Singapore, [3]African Malaria Leaders Alliance, Dar es Salaam, United Republic of Tanzania, [4]Asian Pacific Malaria Elimination Network, Singapore, Singapore, [5]Robert Farlow Consulting LLC, Burkville, TX, United States

National malaria program policies for vector control interventions recommend the universal use of either insecticide treated nets (ITNs/ LLINs) or indoor residual spraying (IRS) with larval source management as a supplemental intervention in certain circumstances. ITNs and IRS have been successful, being responsible for >80% of the reductions in *P. falciparum* malaria in Africa. In this environment of limited recommended interventions choices, vector surveillance has had a limited programmatic role in decision-making. However, the threat posed by increasing insecticide resistance and residual transmission has led to an anticipated rollout of new interventions incorporating new/multiple active ingredients in established and novel interventions. The soon-to-be increasingly complex vector control landscape argues for increased vector surveillance to select the most appropriate vector control measures based on vector ecology and malaria epidemiology. The increasing cost (time and money) of randomized control trials (RCTs) also raises the question of whether vector-monitoring data can replace the RCT as the basis for policy recommendations on new interventions. Questions that vector data must address include "What is the status of vector surveillance in malaria national control programs?", "Do vector monitoring tools have the precision to guide programmatic decisions on deployment of vector control interventions?' Are vector data used today to guide programmatic decisions?", and "Are countries' vector control programs able to collect vector data and use it for decision-making?" Vector surveillance activities of >30 malaria endemic countries in Africa, Asia, the Pacific and the Americans were analysed against best practice recommendations. How vector data is being collected and used today and the limitations of the data argue for an invigoration and investment in the public health entomologist discipline. The need to utilize vector data requires us to elevate the role of the public health entomologist in the decision-making process, especially in countries seeking to eliminate malaria.

1439

PLASMODIUM VIVAX ERYTHROCYTE BINDING PROTEIN GENE COPY NUMBER, BUT NOT DUFFY BINDING PROTEIN, IS SIGNIFICANTLY HIGHER IN MALAGASY ISOLATES THAN IN CAMBODIAN ONES

Camille Roesch[1], Jean Popovici[1], Sophalai Bin[1], Vorleak Run[1], Stéphanie Ramboarina[2], Chetan Eknath Chitnis[3], Inès Vigan-Womas[2], Didier Ménard[4]

[1]Malaria Molecular Epidemiology Unit, Institut Pasteur in Cambodia, Phnom Penh, Cambodia, [2]Immunology of Infectious Diseases Unit, Institut Pasteur de Madagascar, Antananarivo, Madagascar, [3]Malaria Parasite Biology and Vaccines Unit, Institut Pasteur Paris, Paris, France, [4]Unité Biologie des Interactions Hôte-Parasite, Institut Pasteur Paris, Paris, France

Among the five species of *Plasmodium* that infect humans, *P. vivax* is the most widespread, with billions of people at risk in nearly 100 different endemic countries in South America, Africa and Asia. *P. vivax* being responsible for the majority of malaria cases outside Africa, a blood stage vaccine would considerably alleviate the burden inflicted by this parasite. Invasion mechanisms of *P. vivax* are still unclear and the prevailing paradigm that makes the interaction between *Plasmodium vivax* Duffy binding protein (PvDBP) and Duffy antigen receptor for chemokines (DARC) essential for *P. vivax* invasion is questioned since this parasite has been observed in individuals lacking the Duffy antigen. The pathways by which the parasite is able to enter the Duffy negative reticulocytes are unknown but two possible mechanisms have been suggested in the literature: the amplification of the gene coding for PvDBP as well as the involvement of alternate proteins, in particular a newly described Erythrocyte Binding Protein, PvEBP, which is able to bind Duffy negative red blood cells. In this context, to further study these two hypothesis, we analyzed the genomic polymorphisms (copy number variation and sequence polymorphism) in the second exon of PvDBP and PvEBP in isolates from two different locations: Cambodia where the vast majority of people are Duffy positive and Madagascar, where an admixture of Duffy positive and Duffy negative individuals coexists. We also studied the location of polymorphic residues for these two genes by 3-D modeling. Our molecular epidemiology approach demonstrated that PvEBP was far more conserved than PvDBP and that the copy number variation of PvEBP was significantly different between isolates from Cambodia and Madagascar. Interestingly we observed no significant difference for the copy number variation of PvDBP. Those results further strengthen the possible role of PvEBP in the invasion of Duffy negative individuals.

ADULT SEVERE MALARIA PATIENTS WITH ACUTE KIDNEY INJURY PRESENT A DISTINCT VAR PROFILE

Maria Bernabeu[1], Prasad Babar[2], Fergal Duffy[1], Marina Vaz[3], Jennifer Maki[2], Ligia Pereira[2], Anjali Mascarenhas[2], Maria Silveria[3], Edwin Gomes[3], Laura Chery[2], John Aitchison[1], Pradipsinh K. Rathod[2], Joseph D. Smith[1]

[1]Center for Infectious Disease Research, Seattle, WA, United States, [2]Department of Chemistry, University of Washington, Seattle, WA, United States, [3]Department of Medicine, Goa Medical College, Bambolim, Goa, India

Malaria symptoms and mortality rates vary depending on patient age. In areas with lower malaria transmission intensity, such as India, the risk of renal failure, severe jaundice, pulmonary edema, and multi-organ failure increases with age. Despite the different disease spectrum and higher mortality rates in adults, the pathological mechanisms that lead to adult organ complications remain poorly understood. Acute kidney injury (AKI) is one of the most frequent complications in adult severe malaria and it is an independent predictor of mortality. Parasite sequestration in kidney peritubular endothelial cells has been documented in autopsy studies in both children and adults. However, the role that specific parasite binding phenotypes play in the development of AKI has never been studied. To address this question, we analyzed the parasite *var* profile in blood of Indian adults that presented severe malaria with kidney involvement. Patient serum creatinine levels directly correlated with a biomarker of parasite biomass. In addition, machine learning models revealed a divergence of parasite adhesion types in disease complications, with higher DC8 *var* transcripts in AKI patients and higher Group A *var* transcripts in patients with multi-organ failure. Both DC8 and Group A *var* genes encode EPCR binding activity, but Group A binding to endothelium is additionally mediated by ICAM-1. Our findings suggest that AKI is associated with the expansion of DC8 EPCR-binding parasites, and that an expansion of Group A-expressing parasites is present in patients with multi-organ complications. Thus, different parasites might contribute to the variable disease presentations observed in adult patients with severe malaria. This finding has important implications in the future development of malaria adjunctive therapies.

IDENTIFICATION OF HOST IMMUNOLOGICAL AND *PLASMODIUM* INTRINSIC FACTORS INFLUENCING GAMETOCYTES INFECTIVITY TO *ANOPHELES* MOSQUITOES IN THE FIELD

Dinkorma T. Ouologuem[1], Aminatou K. Kone[1], Antoine Dara[1], Nouhoum Diallo[1], Laurent Dembele[1], Fatoumata I. Ballo[1], Cheick Oumar P. Sangare[1], Boubou Sangare[1], Demba Dembele[1], Aboubecrin Haidara[1], Aliou Traore[1], Ogobara K. Doumbo[2], Abdoulaye A. Djimde[1]

[1]MEDRU / MRTC/ FAPH/ USTTB, Bamako, Mali, [2]MRTC/ FMOS/ USTTB, Bamako, Mali

Sustainable malaria prevention and control measures have permitted a significant decrease in the disease burden in many endemic countries. However, the global agenda for malaria elimination and eradication may not be achieved without the development of transmission-blocking interventions. Malaria transmission to the mosquito relies on gametocytes infectivity for the continuation of the ife cycle and the spread of resistant parasites. Identification of biomarkers associated with gametocyte infectivity can help in the development of new therapeutic strategies. This study aimed to identify host and parasite biomarkers related to gametocyte infectivity in the field. From October to December 2017, a cross-sectional study was conducted in Faladje to enroll asymptomatic *Plasmodium ssp*. gametocyte carriers. Gametocyte carriage was assessed by light microscopy. Venous blood was collected for gametocytes purification, plasma collection and direct membrane feeding assay (DMFA) with both whole blood and RBC supplemented with AB serum. Mosquito's oocyte positivity was determined day-8 post feeding. Protein microarrays covering 250 *P. falciparum* antigens were probed with plasma from volunteers. Gametocyte's RNA and DNA were extracted for RNA and DNA sequencing. 70 volunteers were enrolled. For the 68 malaria positive samples used for DMFA, mosquito's infectivity rate was 28% (n=19). The number of oocyst positive mosquito and oocyst load per mosquito were significantly higher in RBC+AB serum DMFA for 73.7% (n= 14) of the infectious sample. Ab levels to 7 antigens were significantly higher in plasma from non-infectious gametocyte blood meals compared to those who were infectious. Candidate antigens included a *Plasmodium* Deoxyhypusine hydroxylase, four putative proteins highly expressed in gametocytes, ookinetes and/or sporozoites, and an ATG autophagic pathway associated protein. Dissecting factors influencing gametocytes infectivity will highlight biomarkers associated with malaria transmission and provide potential targets for transmission blocking strategies and new tools for malaria transmission screening.

FERROPTOSIS-LIKE SIGNALING FACILITATES A POTENT INNATE DEFENSE AGAINST *PLASMODIUM* INFECTION

Alexis Kaushansky

Center for Infectious Disease Research, Seattle, WA, United States

The facets of host control during *Plasmodium* infection, and the mechanisms by which they alter susceptibility in the field, remains largely unknown. Surprisingly, conventional innate regulatory pathways are only minimally effective at eliminating parasites during the Liver Stage of infection. Ferroptosis, a recently described form of iron-dependent cell death that drives accumulation of reactive oxygen species and lipid peroxides, has not yet been shown to function as an innate immune response. We demonstrate that inducing ferroptosis with small molecules or by genetic perturbation of its negative regulators, GPX4 and SLC7a11, dramatically reduces survival of the Plasmodium Liver Stage in mice. Knockdown or knockout of NOX1 or knockdown of TFR1, which are required for ferroptosis, increases the number of Liver Stage parasites. Moreover, we demonstrate that blocking ferroptosis renders parasite-infected hepatocytes resistant to P53-mediated hepatocyte death. Interestingly, preliminary analysis indicates that individuals with differential susceptibility to malaria in Mali exhibit altered levels of ferroptosis-related genes. These findings suggest that the ferroptosis pathway might not only regulate malaria in a mouse model, but may also extend to regulating susceptibility to disease in humans. Our work also raises the possibility that ferroptosis operates as an axis of the innate immune system to defend against intracellular pathogens.

1443

IMPACT OF NATURALLY-ACQUIRED HEMOZOIN ON SEVERE MALARIAL ANEMIA AND ERYTHROPOIESIS AMONG CHILDREN RESIDENT IN *PLASMODIUM FALCIPARUM* HOLOENDEMIC REGION OF KENYA

Samuel B. Anyona[1], Evans Raballah[2], Angela O. Achieng[1], Caroline Ndege[1], Prakasha Kempaiah[3], Collins Ouma[1], Douglas J. Perkins[3]

[1]Maseno University, Maseno, Kenya, [2]Masinde Muliro University of Science and Technology, Kakamega, Kenya, [3]University of New Mexico, Albuquerque, NM, United States

In holoendemic *Plasmodium falciparum* transmission areas, malaria manifests primarily as severe malarial anemia [SMA; hemoglobin (Hb)<5.0 g/dL] among children aged <48 months. Although our *in vitro* studies demonstrate that enhanced uptake of malarial pigment (hemozoin, *Pf*Hz) suppresses immune response genes and gene pathways, the impact of naturally-acquired P*f*Hz on SMA and erythropoietic responses are largely unexplored. Intraleukocytic P*f*Hz and inefficient erythropoiesis (reticulocyte production index; RPI<2.0) were determined among parasitized children (<36 mos.) stratified into SMA (n=280) and non-SMA (Hb≥5.0 g/dL; n=1,032). Pigmented monocyte (PCM) levels (%) were classified as follows: PCM [(-), no PCM], Low PCM (≤10%), Moderate PCM (>10<26.7%), and High PCM (≥26.7%). Demographic (age, admission temperature), hematological parameters, and parasitological indices (parasite density, geomean parasitemia) varied across PCM groups (P<0.001). Proportions of children presenting with SMA and insufficient erythropoiesis also varied across PCM groups (P<0.001). Binary logistic regression analyses, controlling for covariates, demonstrated that presence of PCMs increased susceptibility to SMA [High PCM, odds ratio (OR)=4.957 (95% CI=2.820-8.712), P<0.001; Moderate PCM, OR=3.906 (95% CI=2.299-6.635), P<0.001, and low PCM, OR=1.732 (95% CI=1.154-2.599), P=0.008]. Additional analysis showed that high PCM levels increased the odds of children presenting with RPI≥2.0 [OR=2.827 (95% CI=1.462-5.469), P=0.002]. No associations were observed between RPI≥2.0 and either moderate PCM [OR=1.484 (95% CI=0.721-3.053), P=0.283] or low PCM [OR=1.098 (95% CI=0.643-1.876), P=0.731]. Taken together, these results suggest increased that intramonocytic P*f*Hz is associated with enhanced susceptibility to SMA, an event that appears independent of its effect on erythropoiesis.

NEUREGULIN-1 ATTENUATES EXPERIMENTAL CEREBRAL MALARIA PATHOGENESIS BY REGULATING ERBB4/AKT/STAT3 SIGNALING

Mingli Liu

Morehouse School of Medicine, Atlanta, GA, United States

Human Cerebral Malaria (HCM) is a severe form of malaria characterized by sequestration of infected erythrocytes (IRBC) in brain microvessels, increased levels of circulating free heme and pro-inflammatory cytokines and chemokines, brain swelling, vascular dysfunction, coma and increased mortality. Utilizing an experimental cerebral malaria (ECM) model, we reported that NRG-1 played a cytoprotective role in ECM and that circulating levels were inversely correlated with ECM severity. Intravenous infusion of NRG-1 reduced ECM mortality in mice by promoting a robust anti-inflammatory response coupled with reduction in accumulation of IRBCs in microvessels and reduced tissue damage. In the current study, we explored a potential molecular mechanism by which NRG-1 regulates downstream pathways to improve/restore the integrity of the blood brain barrier (BBB) and attenuate ECM pathogenesis. We examined whether NRG-1 protects against CXCL10- and heme-induced apoptosis using human brain microvascular endothelial (hCMEC/D3) cells and the M059K neuroglial cells. hCMEC/D3 cells grown in a monolayer and a co-culture system with 30μM heme and NRG-1 (100ng/ml) were used to examine the role of NRG-1 on BBB integrity. Using the *in vivo* ECM model, we examined whether the reduction of mortality was associated with the activation of ErbB4 and AKT and inactivation of STAT3 signaling pathways. We found that NRG-1 protects against cell death/apoptosis of human brain microvascular endothelial cells and neroglial cells, the two major components of BBB. NRG-1 treatment improved heme-induced disruption of the *in vitro* BBB model consisting of hCMEC/D3 and human M059K cells. In the ECM murine model, NRG-1 treatment stimulated ErbB4 phosphorylation followed by activation of AKT and inactivation of STAT3, which attenuated ECM mortality. Our results indicate a potential pathway by which NRG-1 treatment maintains BBB integrity *in vitro,* attenuates ECM-induced tissue injury and reduces mortality. Furthermore, we postulate that augmenting NRG-1 during ECM therapy may be an effective adjunctive therapy to reduce CNS tissue injury of HCM.

ANTIBODY TO *PLASMODIUM FALCIPARUM* VARIANT SURFACE ANTIGENS AND TRANSCRIPTION OF VAR GENES IN PAPUA NEW GUINEAN CHILDREN WITH SEVERE OR UNCOMPLICATED MALARIA

Stephen Rogerson[1], Priyanka Barua[1], Michael Duffy[1], Laurens Manning[2], Moses Laman[3], Timothy Davis[2], Ivo Mueller[4], Julie Simpson[1], James Beeson[5]

[1]University of Melbourne, Parkville Victoria, Australia, [2]University of Western Australia, Perth, Australia, [3]Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, [4]Walter and Eliza Hall Institute, Parkville Victoria, Australia, [5]Burnet Institute, Melbourne, Australia

The *Plasmodium falciparum* Erythrocyte Membrane Protein 1 family of proteins mediate sequestration of infected erythrocytes (IEs) in the deep vasculature, contributing to pathogenesis of falciparum malaria. Antibody responses to PfEMP1 proteins develop in convalescence from malaria, particularly against homologous isolates. 71 parasite isolates from children with severe (N=41) or uncomplicated malaria (N= 30) from Papua New Guinea were cultured in first *in vitro* cycle to trophozoite stage and magnet purified. Isolates were divided according to donor ABO

blood group, and incubated with matched homologous and heterologous acute and convalescent plasma. IgG antibodies to variant surface antigens (predominantly PfEMP1) were measured by flow cytometry. We extracted RNA from ring stage IEs and used quantitative real time PCR to assess transcription of 46 *var* genes in 40 isolates which grew in culture. Homologous boosting of antibody in convalescence was common. Among children with non-O blood groups, cluster analysis of antibody profiles showed that in comparison to children on presentation with severe malaria, there were broadly higher levels of antibody to IE surface antigens in convalescence from severe malaria and in acute or convalescent samples from uncomplicated malaria. By contrast, in children with blood group O, only convalescent plasma from severe malaria showed higher recognition of tested isolates. These differences may relate to the differential susceptibility of children with blood group O to severe malaria. Several *var* genes were upregulated in severe malaria including mostly *var* type A, but also some *var* types B/A, B and B/C, while none were upregulated in mild relative to severe malaria. Increased transcription, predominantly of *var* genes associated with severe malaria in Africa, was common in severe malaria in PNG. The relationship between antibody response and *var* gene profiles is currently being investigated and will be discussed.

Jiarakul[4], W. Lausatianragit[1], A. Lover[5], P. Pokpong[8], M. Fukuda[6], K. Jongsakul[6], P. Prempree[2]

[1]Sisaket Provincial Health Office, Sisaket Province, Thailand, [2]Bureau of Vector Borne Disease, Department of Disease Control, Nonthaburi, Thailand, [3]Research Division, Royal Thai Army Component, Armed Forces Research Institute of Medical Sciences Sisaket Provincial Health Office, Bangkok, Thailand, [4]Office of Disease Prevention and Control 10, Ubon Ratchathani, Thailand, [5]University of California San Francisco, San Francisco, CA, United States, [6]US Army Medical Directorate, Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [7]Bureau of Vector Borne Disease, Department of Disease Control, Bangkok, Thailand, [8]Royal Thai Army Component, Armed Forces Research Institute of Medical Sciences Sisaket Provincial Health Office, Bangkok, Thailand

In April 2017, the Thailand Ministry of Public Health (MoPH) reported a malaria outbreak in Sisaket Province, along the Thai-Cambodian border. Between April and November 2017, 713 cases were reported: a five-fold increase from the same time period in 2016. A similar increase in cases (n=119 versus n=16) was found in a Royal Thai Army (RTA) cohort stationed in the Sisaket. The majority of cases were reported from three malaria-endemic districts: Khun Han (47%), Phu Sing (25%), and Kantharalak (24%). Cases were primarily *P. vivax* infections (76%), among males (88%) working in rubber plantations (63%) or as military and/or border police (15%). To stem the outbreak, the Sisaket Provincial Governor launched an Emergency Operations Center (EOC) including representatives of MoPH, RTA and US components of the Armed Forces Research Institute of Medical Sciences (AFRIMS), the University of California, San Francisco, forest service staff, local military personnel, border police, and local administrative organizations. The response focused on three main efforts derived from the MoPH's National Malaria Elimination Strategy: 1) proactive case detection; 2) a "1-3-7" approach, in which both civilian and military malaria cases were reported within 1 day, confirmed and investigated within 3 days and responded to within 7 days; and 3) analysis of genetic markers among *P. falciparum* cases to assess for drug resistance. A total of 6,299 people were screened by microscopy and PCR in 24 high-risk villages and military bases. All cases were promptly treated using supervised treatment. Confirmed cases were followed for up to 90 days, with microscopy smears and dried blood samples collected at each follow-up visit. In addition, 61 key informant interviews were conducted. To date, a total of 24 case investigations among RTA have been conducted. Analysis of the root causes of the outbreak, findings from outbreak response activities, and lessons learned in integrating civilian and military efforts will be presented. The Sisaket outbreak response demonstrates the necessity of civilian-military cooperation to support Thailand malaria elimination goals.

1447

ASSESSMENT OF RESIDUAL MALARIA TRANSMISSION IN LETPAN VILLAGE, SOUTHERN RAKHINE STATE, MYANMAR

Ye H. Naing[1], Saw Lwin[1], Feliciano Monti[2], Khin Than Win[1], Thant Zin Aung[1], Oakar Soe[1], Saw Naung Naung[1], Sway Min Htet[1], May Aung Lin[1], San Kyawt Khine[3], Zaw Lin[3], Kyaw Myint Tun[1]

[1]University Research Co., LLC, Yangon, Myanmar, [2]U.S. President's Malaria Initiative / U.S. Agency for International Development, Yangon, Myanmar, [3]Vector-Borne Disease Control, Ministry of Health and Sports, Nay Pyi Taw, Myanmar

The PMI-supported Defeat Malaria Project continuously monitors malaria data in its target areas. A general pattern of declining malaria has been reported in recent years in project areas, with marked heterogeneity. In Letpan village (South Rakhine State), an increasing Annual Parasite Incidence (API) has been registered despite continuous community-based malaria control activities implemented since 2013. An assessment was performed in 2017 to identify underlying causes of this pattern and suggest appropriate responses. Staff reviewed epidemiological data, conducted a cross-sectional household survey, key informant interviews, and a parasitological survey. The village has 790 residents of Rakhine (85%) and Chin (15%) ethnicities. Approximately 30% Rakhine and most Chin are forest workers. Epidemiological data from 2014 to 2017 revealed an increasing API of 18.3, 15.5, 30.2 and 40.4, respectively. Receptivity analysis showed intrusion of river water creating small ponds, some water reservoirs during the rainy season, and nearby paddy fields. A village malaria worker was recruited in July 2013 and Annual Blood Examination Rates were over 10% from 2014 through 2017. Nearly 62% of villagers reported sleeping under an insecticide-treated net the previous night. From 5 to 9 PM, 97% of respondents reported staying outdoors, increasing exposure to mosquitoes bites. A parasitological survey of 232 people (29% of total population) conveniently sampled, conducted in August 2017, did not detect any malaria positive case by conventional RDT. A detailed review of malaria cases reported from October 2016 to September 2017 revealed that 30 out of 32 cases (94%) were forest workers and 4 were children under-5 who accompanied family members into the forest. Letpan's residual malaria transmission, despite good coverage of malaria services, is most likely due to the risk group of forest-goers infected outside the village, and Letpan has been classified as a residual non-active focus. Active surveillance of fever cases among returning forest goers, and intensified measures to prevent vector-human contacts among forest goers should be strengthened.

1448

CASE BASED MALARIA SURVEILLANCE SYSTEMS IN ELIMINATION SETTINGS OF ZANZIBAR

Humphrey R. Mkali[1], Abdullah S. Ali[2], Abdul-wahid Al-mafazy[2], Mohamed H. Ali[2], Erik Reaves[3], Naomi Kaspar[4], George Greer[4], Wahida S. Hassan[2], Joshua Yukich[5], Willis Odek[1]

[1]MEASURE Evaluation, Dar Es Salaam, United Republic of Tanzania, [2]Zanzibar Malaria Elimination Programme, Zanzibar, United Republic of Tanzania, [3]US President's Malaria Initiative, US Centers for Disease Control and Prevention, Dar Es Salaam, United Republic of Tanzania, [4]US President's Malaria Initiative, United States Agency for International Development, Dar Es Salaam, United Republic of Tanzania, [5]Center for

Applied Malaria Research and Evaluation, Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States

Since 2012, ZAMEP has operated both a passive, facility-based and active case-based surveillance and response system for malaria. In 2017, ZAMEP enhanced the case-based system to capture additional information to permit the classification of individual malaria cases and their associated *Foci* according to WHO definitions. Our objectives were to describe the classification of malaria cases and the *Foci* investigated in Zanzibar. All health facilities report individual malaria cases to the central server in real time using mobile phone. Messages transmitted from the server alert the respective District Malaria Surveillance Officer, who obtains detailed clinical and epidemiological information about individual cases through the health facility that reported the case and during case follow-up and *Foci* investigations at household level. All household members receive testing and treatment (if positive). Malaria cases and *Foci* are classified by WHO definitions. From January 2017 to February 2018, a total of 774 cases were reported from 78 facilities, with 76 *Foci* investigated and classified. During case investigation, 68.9% cases were classified as imported, 27.4% cases as indigenous, 2.7% cases as introduced, 0.8% cases as relapsed, and 0.3% cases as induced. During *Foci* investigation, 55.2% *Foci* were classified as residual active and 44.8% *Foci* were classified as residual non-active. Geographically, 13 *Foci* were identified in Pemba, of which 46.2% residual active *Foci* were in Micheweni district and 53.8% in Chake chake district. In Unguja, 29 residual active *Foci* were identified; 62.1% *Foci* in North B, 20.7% *Foci* in West, and 17.2% *Foci* in Urban. The enhanced case-based surveillance system demonstrates that case and *Foci* investigations and classification are feasible in Zanzibar. Interventions focusing on imported cases, alongside other interventions for residual active *Foci* might reduce malaria transmission and morbidity, and accelerate malaria elimination efforts in Zanzibar.

ACCESSING HARD-TO-REACH POPULATIONS: FOREST INTERVENTIONS INCREASE CASE DETECTION IN PURSAT PROVINCE, CAMBODIA

Sokomar Nguon[1], Samphornarann Top[1], Linna Khorn[1], Sovann Ek[1], Kongmeng Seak[1], Yom An[1], Phally Chhun[1], Say Mang[1], Rida Slot[2], Gunawardena Dissanayake[2], Rekol Huy[3], Pisal Heng[3], Huch Chea[3], Sochantha Tho[3], Sovannaroth Siv[3], Po Ly[3], Dy Khoy[4], Kimen Ke[4], Manuth Peou[4], Tamar Gabunia[1], Sharon Thangadurai[1], Paul Bacon[1], Neeraj Kak[5], Soy Ty Kheang[1]

[1]University Research Co., LLC, Phnom Penh, Cambodia, [2]President's Malaria Initiative, U.S. Agency for International Development, Phnom Penh, Cambodia, [3]National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, [4]Provincial Health Department, Pursat, Cambodia, [5]University Research Co., LLC, Chevy Chase, MD, United States

In Cambodia, malaria risk is highest in forest or forest fringe areas, linked to the movement of people going into the forest. To better target high-risk groups working in these areas, USAID | PMI Cambodia Malaria Elimination Project (CMEP) supports the Cambodia National Malaria Program (CNM) to train mobile malaria workers (MMWs) where volunteers are selected from these at-risk groups to provide early diagnosis and treatment to mobile and migrant populations (MMPs). Starting in May 2017, a significant increase in malaria cases in Phnom Kravanh (PKV) and Krakor (KRK) operational districts (ODs) required CNM, CMEP and OD team members to analyze and identify health facilities, villages and hotspots for investigation and response. Based on case numbers, three villages were targeted. Interventions included hotspot investigation and response activities (public announcement, bed net top up, health education, mass screening and treatment). Screening results showed a 0.7% test positivity rate (TPR), with the largest village not identifying any positive cases. These findings suggested that village-based screening was missing the high-risk groups. CMEP and OD teams initiated expansion of MMW pro-active case detection (Pro-ACD) in the forest. Learning where malaria was contracted from ex-patients, 6 touch points (where forest goers interacted) and 22 worksites were identified with 18 volunteers selected and trained as MMWs. From Aug 2017-Feb 2018, 1,708 people were tested and 423 were confirmed and treated in PKV and KRK (TPR 25%). A high TPR (38%, of which 66% were *P. falciparum*) was found by MMWs in the forest in PKV from screening at touch points and work sites. In forest and forest fringe areas, mass screening in villages is not enough to reduce or stem the spread of malaria outbreaks. Expansion of services into hotspots through MMW Pro-ACD at touch points and worksites is effective in identifying reservoirs of malaria burden among MMPs, particularly forest goers/workers. A scale up of malaria services into the forest may improve the effectiveness of malaria programs. However, active multi-stakeholder collaboration and coordination is required.

Human movement is a known contributor to sustained malaria transmission in low endemic areas. Many methods have been explored to measure human mobility and its impact of movement to malaria transmission, for example, census data, travel diaries, mobile phone usage data and GPS trackers. Our study used commercially available GPS data trackers to identify specific potentially high-risk locations visited frequently by forest workers in the district of Aceh Besar and Aceh Jaya in Aceh Province, the western province of Indonesia. These districts previously reported the presence of zoonotic malaria species *Plasmodium knowlesi* among forest workers. Beginning in April 2017, we recruited forest workers who were recent malaria cases, as well as individuals from their peer networks, to be followed for a period of two months each. Following consent, individuals were asked to wear an "i-gotU" (i-gotU model GT100) GPS tracking device continually during all of their activities over a two month period; location data were captured every 15 minutes. As of April 2018, 62 individuals had been recruited into the study, 38 of whom completed the study or dropped out before the end of the 2 month data collection period. Data collection for an additional 24 individuals is ongoing and participant recruitment will continue through September 2018. To date, participants have contributed 1,691 days of GPS data collection with over 236,000 data points. More comprehensive analysis on the individual movement patterns to inform interventions that target for mobile forest workers will be presented.

Gambia, [6]Makerere University - Johns Hopkins University Research Collaboration, Kampala, Uganda, [7]Malaria - African Leaders Malaria Alliance, Kampala, Uganda, [8]Stanford University, Stanford, CA, United States, [9]University of Califofnia San Francisco, San Francisco, CA, United States

There is limited evidence of reductions in malaria burden in high transmission areas of Africa. Understanding the impacts of malaria control interventions is critical to guide strategies for malaria control in hyper-endemic regions. Over a 10-year period (2007-2017), we measured the impact of various malaria control interventions in cohorts of children enrolled in 7 clinical trials and observational studies in Tororo, Uganda, a historically high transmission area with a baseline annual EIR of 310. Interventions included individually assigned chemoprevention regimens, population level universal LLIN distribution in November 2013 and repeated rounds of IRS starting in December 2014. All children received LLIN at enrollment and standardized approaches were used to follow cohort participants including prompt treatment for malaria with ACTs. We measured the incidence of malaria using passive surveillance and parasite prevalence by microscopy at regularly scheduled routine visits. Meta-analyses of a combined data set were performed to estimate the protective efficacy (PE) of the various control interventions. A total of 2148 children were followed over 5136 person years resulting in16698 treatments for malaria, including only 116 (0.7%) treatments for severe malaria and 2 deaths with malaria. Considering observation time between 0.5-2 years of age, in the absence of chemoprevention and before the implementation of IRS (reference group), the incidence of malaria was 5.0 episodes per person year (PPY) and parasite prevalence was 15.2%. The most dramatic declines followed the implementation of IRS (malaria incidence 0.47 episodes PPY, 90% PE; parasite prevalence 3.9%, 74% PE) and especilally among children receiving chemoprevention with monthly DP (malaria incidence 0.03 episodes PPY, 99.5% PE; parasite prevalence 0.9%, 94% PE). In our cohorts, where we provided LLINs and prompt treatment with ACTs, the risks of severe malaria and death were extremely low. In a historically high malaria burden area of Uganda, the combination of IRS and chemoprevention with monthly DP has almost eliminated malaria in young children.

[1]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]Broad Institute of MIT and Harvard, Cambridge, MA, United States, [3]PATH MACEPA, Seattle, WA, United States, [4]Senegal National Malaria Control Program, Dakar, Senegal, [5]District Medical Chief, Richard Toll District, Richard Toll, Senegal, [6]Senegal National Malaria Control Program, Dakar, Senegal, [7]Dantec Teaching and Research Hospital, Dakar, Senegal, [8]PATH MACEPA/ISGlobal Collaboration, Barcelona, Spain, [9]Harvard University, Cambridge, MA, United States, [10]Cheikh Anta Diop University Health, Dakar, Senegal

Senegal has three distinct malaria transmission zones ranging from relatively high incidence rates in the South (> 250/1000) to very low incidence rates (< 2/1000) in the North. The majority (~85%) of clinical malaria cases in the northern Senegal district of Richard Toll are found among individuals with a travel history and are therefore classified as representing imported infection, as previously reported. We compared genetic relatedness between parasite infections and travel history to test the hypothesis that local infections occur in Richard Toll. Previous studies using genetic relatedness reveal increased proportions of highly related parasites in low transmission settings, with evidence of clonal parasites that persist across multiple transmission seasons[2]. We successfully genotyped 646 RDT-positive samples collected in Richard Toll district between 2012 and 2015 using a molecular barcode tool that assesses 24-single nucleotide polymorphisms. The majority (471/646 = 73%) of these represented monogenomic infections (expected with low transmission intensity), with increased polygenomic infections among those with travel history (p = 0.03). Consistent with local transmission, we detected eight persistent clonal lineages in multiple years from 2012 and 2015, mainly among individuals with no travel history. We also observed clusters of genetically identical infections within households with no travel history (p = 0.03). Despite limited data from across Senegal, we were able to identify (6%) parasites that were identical or closely related to parasites being actively transmitted in Dakar, Thies, Kaolack, and Touba. These results demonstrate connectivity with other parts of Senegal and receptivity for transmission within Richard Toll. These findings reveal indigenous transmission is likely in this very low prevalence region, and underscores the utility of genomic data to resolve malaria transmission patterns to stratify interventions for successful malaria elimination.

IMMUNITY AND MEMORY AGAINST MALARIA: AN ATLAS OF THE MOSQUITO IMMUNE SYSTEM AT SINGLE CELL RESOLUTION

Gianmarco Raddi[1], Carolina Barillas-Mury[2], Oliver Billker[3]

[1]NIH / University of California Los Angeles / University of Cambridge / Wellcome Trust Sanger Institute, Rockville, MD, United States, [2]National Institutes of Health, Rockville, MD, United States, [3]Wellcome Trust Sanger Institute, Cambridge, United Kingdom

Malaria is a deadly, worldwide disease. Every year the *Plasmodium* parasite is responsible for an estimated 214 million cases of malaria and over four hundred thousand deaths. In order to infect humans, *Plasmodium* parasites must complete their life-cycle in mosquitoes. The mosquito in turn relies on both humoral and cellular innate immune divisions to defeat invading pathogens, coordinated by the hemocytes. Hemocytes are the equivalent of vertebrate innate white blood cells, circulating in the hemolymph within the insects' body cavity. However, basic hemocyte cell biology and immunological effector mechanisms are largely unknown, mainly due to the small number of immune cells in each mosquito. Developing an in depth understanding of the mosquito immune system will help clarify malaria transmission dynamics and prove useful in developing novel vector control and transmission-blocking strategies. Here we profile 5,292 individual *Anopheles* mosquito hemocytes in baseline, blood-fed and malaria-infected conditions with single-cell RNAseq. We combine scRNA-seq data with low input bulk RNAseq, FISH, electron and confocal microscopy to identify previously unknown cell types and uncover their lineages and transcriptional signatures. Among the novel mosquito immune cells discovered are specialised immune-regulatory, phagocytic, and anti-microbial peptides secreting cell subtypes. We also report shifts in the activation level and composition of the immune cells repertoire of mosquitoes infected with malaria parasites. Analysis shows the existence of three polarized immunological states: suppressed, primed, and malaria-activated. We also report networks of immune regulation centered around SRPNs proteins specific for each immune cell subtype. This is the first comprehensive study of an invertebrate innate immune system at single-cell resolution. Far from being static, the mosquito immune system is revealing a surprising degree of complexity that we are only beginning to explore.

THE FEMALE REPRODUCTIVE PROTEIN (MATING-INDUCED STIMULATOR OF OOGENESIS, MISO) REGULATES TOLERANCE TO *PLASMODIUM FALCIPARUM* INFECTION IN *ANOPHELES GAMBIAE*

Perrine Marcenac[1], Adam South[1], Victoria A. Ingham[2], Evdoxia G. Kakani[1], Sara N. Mitchell[1], W. Robert Shaw[1], Daniel G. Abernathy[1], Serge R. Yerbanga[3], Thierry Lefevre[4], Abdoulaye Diabate[3], Hilary Ranson[2], Flaminia Catteruccia[1]

[1]Harvard T. H. Chan School of Public Health, Boston, MA, United States, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]Institut de Recherche en Sciences de la Sante/Centre Muraz, Bobo-Dioulasso, Burkina Faso, [4]Institut de Recherche pour le Developpement, Montpellier, France

In *Anopheles gambiae*, male-female molecular interactions following mating are important determinants of female reproductive fitness - a key component of vectorial capacity. Sexual transfer of the steroid hormone 20-hydroxyecdysone (20E) induces a large-scale transcriptional response that permanently reshapes female physiology and also impacts blood feeding-induced processes through interaction with the female protein Mating-Induced Stimulator of Oogenesis (MISO), increasing expression of lipid transporters and boosting fecundity. Furthermore, the factors modulated by the 20E-MISO interaction post-mating are the same that *Plasmodium falciparum* parasites utilize for their own development. Here, we present data demonstrating that in *A. gambiae,* 20E transferred during mating confers female tolerance to *P. falciparum* infection through *MISO*, as silencing of this gene leads to decreased egg production in infected females relative to uninfected and infected controls. Immunofluorescence assays, qRT-PCR, and Western blotting reveal that MISO is produced in the reproductive tissues, including the ovaries and atria, as well as in the trachea oxygenating the ovaries. Correlation network and transcriptional analysis suggest MISO is involved in conserved molting and oxygen-sensing signaling pathways, providing new insight into molecular processes important for egg development in *A. gambiae*. Importantly, species that lack sexually-transferred 20E, including the Central American vector *A. albimanus*, suffer a fitness cost to *P. falciparum* infection, suggesting that divergent evolutionary trajectories of female post-mating physiology across anopheline species may have differentially affected their ability to support *Plasmodium* transmission. The results of these studies elucidate new molecular pathways critical to *A. gambiae* vectorial capacity that may have been shaped by millions of years of pressure from *Plasmodium* parasites.

GLOBAL MAPPING OF MIRNA-MRNA INTERACTIONS IN THE MALARIA MOSQUITO *ANOPHELES GAMBIAE*

Xiaonan Fu[1], Pengcheng Liu[1], George Dimopoulos[2], **Jinsong Zhu**[1]

[1]Virginia Tech, Blacksburg, VA, United States, [2]Johns Hopkins University, Baltimore, MD, United States

Mosquito-borne infectious diseases are resurging and emerging threats to human health. Female mosquitoes transmit the causative pathogens while taking blood from vertebrates to acquire nutrition for egg production. Decoding the gene regulation that governs mosquito reproduction and innate immunity will potentially open new avenues to develop effective strategies for disease control. Recent studies have suggested that mosquito miRNAs contribute to the tightly controlled stage-specific gene expression before and after blood feeding. However, the molecular targets of these miRNAs have not been explicitly identified in mosquitoes. The lack of widely applied rules for functional miRNA-target pairing makes it difficult to accurately predict the miRNA targets. Moreover, an increasing body of evidence from other animals indicates that many miRNA-mRNA interactions are context-dependent. In this study, we used an experimental approach to perform a global analysis of the miRNA-mRNA interaction network in *Anopheles gambiae*. By ligating miRNA and target mRNA in the Ago1-RNA complexes using the CLEAR-CLIP method, we uncovered tens of thousands of miRNA-mRNA interactions in the mosquito. After identifying the common motifs shared by the targets of individual miRNAs, we were able to determine how each miRNA recognized their mRNA targets. The interactions comprised canonical seed-based pairing with diverse patterns of auxiliary pairing and seedless targeting. Interestingly, some miRNAs (e.g. miR-276-3p) have shown to use various regions to recognize their targets at different developmental stages. Comparison of the miRNA-mRNA interactomes at multiple time points revealed that the dynamic miRNA-mRNA interactions coordinate the gene regulation in a stage-specific manner. This study identified a subset of miRNAs that are implicated in metabolism, energy homeostasis, and egg maturation, shedding light on future functional studies.

NEW INSIGHTS INTO THE AMMONIA METABOLISM OF BLOOD-FED *AEDES AEGYPTI* MOSQUITOES

Patricia Y. Scaraffia[1], Thomas D. Horvath[2], Shai Dagan[3], Philip L. Lorenzi[2], David H. Hawke[2]

[1]Tulane University, New Orleans, LA, United States, [2]University of Texas MD Anderson Cancer Center, Houston, TX, United States, [3]Israel Institute for Biological Research, Ness Ziona, Israel

Mosquitoes are responsible for the transmission of serious diseases including malaria, dengue hemorrhagic fever, chikungunya fever, and Zika virus. Many of these infections prove fatal. To resolve this devastating worldwide problem, we strive to identify new metabolic targets or regulators to implement more effective strategies for vector control. Ammonia, one of the metabolic by-products of blood meal digestion, cannot be stored inside cells and therefore nitrogen metabolism in blood-fed mosquitoes must be tightly regulated to prevent ammonia toxicity. Because the majority of the carbon skeletons of amino acids (AAs) derived from protein meal digestion are completely oxidized for energy production, we hypothesized that the carbon skeleton of glucose supplies the keto acids necessary for the synthesis of AAs and other compounds during ammonia detoxification. To test that hypothesis, we fed *Aedes aegypti* females with a blood meal supplemented with [1,2-$^{13}C_2$]-glucose, and monitored the kinetics of 43 compounds and 272 isotopologs during a time course. We carried out the experiments using low- and high-resolution liquid chromatography mass spectrometry (LC/MS) techniques. Interestingly, only 11 metabolites exhibited [^{13}C]-atom incorporation from [1,2-$^{13}C_2$]-glucose. We discovered that the carbon skeleton of glucose supports ammonia detoxification through the synthesis of specific AAs, AA derivatives, and organic acids including uric acid. We also found that the synthesis of these compounds occurs through a complex interplay between glycolysis, pentose phosphate pathway, decarboxylation of pyruvate, Krebs cycle, and pathways involved in ammonia fixation, assimilation, and excretion. In summary, we discovered a metabolic link at the carbon atomic level in ammonia metabolism of blood-fed *Aedes aegypti*. The mass spectrometry techniques optimized in this study can be applied to investigate the metabolic regulation of nitrogen and carbon metabolism in mosquitoes and in other vectors of diseases, and ultimately could lead to the discovery of metabolic targets or regulators for vector control.

1457

THE ROLE OF BIOFILM FORMATION IN THE MOSQUITOCIDAL ACTIVITY OF *CHROMOBACTERIUM* SPECIES FROM PANAMA

Hannah J. MacLeod, Sarah M. Short, Raúl G. Saraiva, Eric P. Caragata, George Dimopoulos

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

In the face of increasing resistance in *Anopheles* mosquitoes to our frontline insecticides, new tools are desperately needed for malaria vector control. We have isolated a *Chromobacterium* species from Panama

*(C.*sp_P*)* that possesses antiparasitic, antiviral, and entomopathogenic properties. We investigated the adulticidal activity of *Csp_P* to female *Anopheles* mosquitoes in order to identify the mechanism of *C.*sp_P's entomopathogenicity as well as to evaluate its viability as the basis for a new vector control tool. *C.*sp_P was cultured for 72 hours at 30°C in either planktonic (shaking) or biofilm (stationary) conditions. We observed differential mortality patterns in *An. gambiae* treated with biofilm culture compared with those treated with planktonic culture, with the biofilm causing faster mortality in a higher proportion of mosquitoes. This indicated to us that the formation of a biofilm may be related to the entomopathogenic activity of members of the *Chromobacterium* genus. We investigated the effects of different biofilm inhibitors on the adulticidal activity of *C.*sp_P as well as *Chromobacterium violaceum*, which forms a more identifiable biofilm through its production of purple violacein pigment. Adulticidal activity of these bacteria appeared related to both biofilm formation and the number of live bacteria in the biofilm culture preparation. Many *Chromobacterium* species proteins are only expressed under quorum-sensing conditions, such as chitinases, which could be involved in lethal damage to the mosquito after ingestion. Ongoing investigation addresses whether or not *C.*sp_P and *C. violaceum* are capable of forming a biofilm within the gut of the mosquito when fed at high enough concentrations, and what factors are produced by quorum-sensing *Chromobacterium* that lead to mosquito death, and therefore could be leveraged into tools for reducing malaria burden in endemic regions.

1458

NADPH IS CRITICALLY NEEDED FOR FECUNDITY AND INSECTICIDE DETOXIFICATION IN *ANOPHELES GAMBIAE*

Cody J. Champion, **Jiannong Xu**

New Mexico State University, Las Cruces, NM, United States

Redox reactions are ubiquitously involved in various biochemcal activities. It is vital to maintain redox homeostasis in response to the fluctuation of redox shift in various biological contexts. NADPH-dependent reducing capacity is one of the key factors contributing to the redox homeostasis. To understand the redox capacity and its impact on mosquito fecundity and susceptibility to insecticides in *Anopheles gambiae*, we examined the dynamics of oxidative state via induction by paraquat (PQ) and the inhibition of NADPH regeneration by 6-aminonicotinamide (6AN). In naïve conditions, inherent oxidative state varies between individuals, as measured by GSSG/GSH ratio. A high GSSG/GSH ratio was negatively correlated with fecundity. Both PQ and 6AN feeding increased GSSG/GSH ratio and elevated protein carbonylation, a marker of oxidative damage of proteins. Both pro-oxidants lowered egg production. Co-feeding the pro-oxidants with antioxidant lycopene attenuated the adverse effects on fecundity, implying that oxidative stress was the cause of this phenotype. Pre-feeding with 6AN or co-application with PQ resensitizes DDT resistant mosquitoes to insecticides. These results indicate that redox state is delicate in mosquitoes, manipulation of NADPH pool may adversely affect fecundity and insecticide detoxification capacity. Pentose phosphate pathway (PPP) is a major source for NADPH regeneration. Genetic variations in the pathway genes may affect the functionality. Ribose-5-phosphate isomerase (RPI) isomerizes ribulose-5-phophate to ribose-5-phosphate in the PPP. We identified an Arg24Trp variant in the RPI gene in wild *An. gam*biae populations. Interestingly, the variant is overrepresented in kdr positive populations. Further studies are required to gain further understanding of the redox capacity and insecticide detoxification.

1459

IRON TRANSPORTERS AND THEIR ROLES IN *AEDES AEGYPTI*

Hitoshi Tsujimoto[1], Michelle A. Anderson[2], Kevin M. Myles[1], Zach N. Adelman[1]

[1]Texas A&M University, College Station, TX, United States, [2]Virginia Tech, Blacksburg, VA, United States

Aedes aegypti is the major vector of viral pathogens, such as dengue, Zika and chikungunya. Despite their impacts on public health, only one vaccine against dengue, whose utility remains to be established, is currently available for prevention. Therefore, to control the transmission of these viruses, intervention of mosquito vectors is one of the most effective strategies. We focused on mosquito's blood iron utilization since blood contains potentially fatal amount of iron along with its high protein content that they use for reproduction. Using our newly developed cell-based screen, we identified three genes as putative iron transporters from ZIP and ZnT families, whose members were previously known to transport iron or divalent metals. Among these, AaeZIP13, an ortholog of *Drosophila* iron transporter dZIP13, was prominently up-regulated after blood meal. RNAi gene silencing of AaeZIP13 delayed transport of iron out of the midgut. Manipulation of these genes and other iron transporters may disrupt the life cycle of the vector mosquitoes and reduce transmission of the viruses.

1460

PIGGYBAC-MEDIATED STABLE INTEGRATIVE TRANSFECTION OF THE HUMAN FILARIAL PARASITE *BRUGIA MALAYI*

Canhui Liu[1], Amruta Mhashilkar[1], Johan Chabnon[1], Shulin Xu[1], Sara Lustigman[2], John Adams[1], **Thomas R. Unnasch**[1]

[1]University of South Florida, Tampa, FL, United States, [2]New York Blood Center, New York, NY, United States

The human filarial parasites cause diseases that are among the most important causes of morbidity in the developing world. The elimination programs targeting these infections rely on a limited number of drugs, making the identification of new chemotherapeutic agents a high priority. The study of these parasites has lagged due to the lack of reverse genetic methods. The slow progress in the development of reverse genetics in filaria can be attributed to the biology of these organisms, which are obligate parasites that cannot be cultured outside of their hosts. Here, we report the development of a novel co-culture method that results in developmentally competent infective larvae of one of the human filaria (*Brugia malayi*) and describe a method to efficiently transfect the larval stages of this parasite. We describe the production of constructs that result in stable integrative transfection using the *piggyBac* transposon system and a secreted luciferase that can be used as a selectable marker to identify transgenic parasites. We describe the production and use of dual reporter plasmids containing both a secreted luciferase selectable marker and fluorescent protein reporters that will be useful to study temporal and spatial patterns of gene expression. The methods and constructs reported here will permit the efficient production of transgenic filarial parasite lines, allowing reverse genetic technologies to be applied to the human filarial parasites for the first time.

1461

CONTROLLED HUMAN INFECTION WITH SINGLE-SEX *SCHISTOSOMA MANSONI* CERCARIAE

Marijke Langenberg, Marie-Astrid Hoogerwerf, Jacqueline Janse, Janneke Kos-van Oosterhoud, Carola Feijt, Claudia de Dood, Munisha Ganesh, Arifa Ozir-Fazalakhan, Yvonne Kruize, Beatrice Winkel, Gerdien Hardeman, Petra Verbeek-Menken, Martha van der Beek, Eric Brienen, Angela van Diepen, Paul Corstjens, Leo Visser, Lisette van Lieshout, Hermelijn Smits, Pauline Meij, Govert van Dam, Ron Hokke, Maria Yazdanbakhsh, **Meta Roestenberg**

Leiden University Medical Center, Leiden, Netherlands

Controlled human infections (CHI) provide a core platform to accelerate the development of novel drugs and vaccines for infectious diseases and reduce the risk of failure in downstream clinical development. For schistosomiasis, no such model exists. To develop a CHI model for schistosomiasis we have taken the important conceptual step to produce single-sex *Schistosoma mansoni* cercariae according to regulatory requirements for human use. Single-sex worms cannot deposit eggs and consequently pathology is avoided when infecting healthy volunteers. We now report the final data of a dose-escalating clinical trial infecting 17 healthy volunteers to assess the safety, tolerability and infectivity male *Schistosoma mansoni* cercariae in a controlled human infection model. We exposed groups of three to eight volunteers each to 10, 20 and 30 male *Schistosoma mansoni* cercariae and present the safety data of these groups. No serious adverse events occurred. Infection with 10 cercariae was well tolerated with mild adverse events mainly related to the skin penetration of the parasites. Infection with 20 or 30 cercariae was associated with Katayama syndrome in two volunteers. Serum circulating anodic antigen (CAA) levels were measured in weekly samples and peaked at 6-8 weeks following infection. All volunteers were treated with 40mg/kg praziquantel and CAA levels were followed over time. In conclusion, we have established a male *Schistosoma mansoni* controlled human infection model. We show that a limited number of volunteers will suffer from Katayama syndrome after infection with 20-30 male *Schistosoma mansoni* cercariae. We conclude that this model is safe and leads to detectable CAA levels in serum which can be followed over time. Future studies will focus on establishing a female controlled infection model as well as performing reinfection studies.

1462

SCHISTOSOMES DO NOT AND CAN NOT OXIDIZE FATTY ACIDS

Michiel L. Bexkens[1], Mirjam M. Mebius[1], Martin Houweling[2], Jos F. Brouwers[2], Aloysius G. Tielens[1], **Jaap J. van Hellemond**[1]

[1]Erasmus University Medical Centre, Rotterdam, Netherlands, [2]Utrecht University, Fac. Vet. Medicine, Utrecht, Netherlands

Blood flukes of the genus *Schistosoma* cause schistosomiasis that affects over 200 million people in (sub)tropical areas. Recently, fatty acid oxidation was suggested to be an attractive target for drug development, as inhibitor studies suggested that fatty acid oxidation was essential for egg production by female schistosomes. This observation was surprising as the energy metabolism of adult schistosomes was always thought to be strictly dependent on carbohydrates and glycolysis, as adult schistosomes are known to mainly degrade external glucose to lactate. To address these opposing reports on the energy metabolism of adult schistosomes, we performed a comprehensive metabolic study using [^{14}C]-labelled fatty acids. These experiments demonstrated that adults, eggs and miracidia do not oxidize fatty acids, as [^{14}C]-labelled carbon dioxide was never produced. Detailed reanalysis of the *S. mansoni* genome revealed that the postulated genes for fatty acid catabolism (beta-oxidation) were incorrectly annotated. Our new analysis revealed that schistosomes actually lack the capacity to oxidize fatty acids, as the genes for the corresponding enzymes are not present in their genome. Therefore, they cannot oxidize fatty acids in any life-cycle stage. However, uptake and metabolism of fatty acids is indeed crucial for egg production, which fits with the earlier observations that fatty acid starvation and inhibition of fatty acid processing blocks egg production. The adult female schistosome needs to take up and handle large quantities of fatty acids, because the secreted immature eggs comprise a large amount of fatty acids that are present as triacylglycerol in lipid droplets. These stored fatty acids are subsequently used by the developing larvae for anabolic processes, such as phospholipid biosynthesis, required for membrane synthesis in the growing miracidium. In conclusion, fatty acids are essential for adult schistosomes for anabolic processes but our results show that fatty acids are not used for ATP production by beta-oxidation as schistosomes do not and cannot oxidize fatty acids.

1463

PYRUVATE IS ESSENTIAL FOR *WOLBACHIA-BRUGIA MALAYI* SYMBIOSIS

Denis Voronin[1], Alexandra Grote[2], Elodie Ghedin[2], Thomas R. Unnasch[3], Sara Lustigman[1]

[1]Lindsley F Kimball Research Institute, New York Blood Center, New York, NY, United States, [2]Center for Genomics and Systems Biology, New York University, New York, NY, United States, [3]University of South Florida, Tampa, FL, United States

Human lymphatic filariasis is caused by the parasites *Wuchereria bancrofti, Brugia malayi* and is the second leading cause of global disability, affecting more than 120 million people worldwide. *B. malayi* has evolved a mutualistic association with *Wolbachia* (*w*Bm), its obligate intracellular bacteria. *Wolbachia* are crucial for worm fertility and viability, and have been identified as drug targets for new anti-filarial treatments. While the bacteria and parasite are known to share essential metabolic and biosynthetic processes (glycolysis, nucleotide biosynthesis, iron metabolism), the involvement of the glycolytic pathway in the bacteria-host relationship hasn't yet been determined. The *w*Bm genome is missing two key glycolytic enzymes, and potentially can't convert glucose to pyruvate independently. We have shown that *B. malayi* glycolytic enzymes are anchored to the surface of bacteria, indicating that host glycolysis provides pyruvate to the endosymbiont. In this study, we confirmed that pyruvate is essential for *w*Bm and that glycolysis performed by *B. malayi* is likely a major source of the pyruvate. Incubation of *B. malayi* in medium containing a high amount of pyruvate increased the *w*Bm loads in worms. Moreover, the bacterial genes responsible for encoding enzymes that utilize pyruvate in bacterial metabolic reactions (gluconeogenesis (wBm0209), TCA cycle (wBm0207)) were over expressed by more than 2-fold during pyruvate treatment. Conversely, specific inhibition of the host glycolytic enzymes resulted in a decrease in the *w*Bm load and a reduction in worm fertility and viability. The fitness of worms and the number of *w*Bm could be restored by supplementing the treated worms with extra pyruvate in the culture medium. We discuss whether other intracellular sources of host pyruvate, such as lactate, could be used by the endosymbiont as an alternative source of pyruvate. We hypothesize that the local clustering of host glycolytic enzymes together with LDH at the surface of *w*Bm helps to regulate the local concentration of glycolytic products, including pyruvate, to be used by the endosymbiont as an energy source or for gluconeogenesis.

EXTRACELLULAR VESICLES RELEASED FROM FILARIAL PARASITES ARE ENRICHED IN MTOR REGULATORY MICRORNAS

Sameha Tariq[1], Sasisekhar Bennuru[1], Abdel Elkahloun[1], Weiwei Wu[1], Sukhbir Kaur[1], Michael Kimber[2], Thomas B. Nutman[1], Roshanak Tolouei Semnani[1]

[1]National Institutes of Health, Bethesda, MD, United States, [2]Iowa State University, Ames, IA, United States

We have previously shown that the microfilarial (mf) stage of *Brugia malayi* can inhibit the mammalian target of rapamycin (mTOR; a conserved serine/threonine kinase critical for immune regulation and cellular growth) in human dendritic cells (DC) and we have proposed that this mTOR inhibition is associated with the DC dysfunction seen in filarial infections. Because extracellular vesicles (EV) contain many proteins and nucleic acids such as microRNAs (miRNAs) that affect a variety of cellular pathways, we hypothesized that EV secreted from mf are enriched in miRNAs that target and downregulate the mTOR pathway in human DC. Thus, EV, purified from mf of *Brugia malayi* and confirmed by morphology and size through electron microscopy and Nanosight analysis, were assessed by miRNA microarrays and shown to be enriched (>2fold, p-value<0.05, FDR<0.1) for miR100, miR71, miR34, miR7, and let-7. After confirming their presence in EV using qPCR for these miRNA targets, web-based target predictions (using MIRPathv3, TarBAse and MicroT-CD) demonstrated that miR100 and let-7 targeted mTOR and its downstream regulatory protein 4E-BP1 respectively. After confirming the internalization of mf-derived EV by DC using confocal microscopy, we were able to demonstrate through western blotting, that mf EV downregulate the phosphorylation of 4E-BP1 in human DC to the same degree that rapamycin (a known mTOR inhibitor) does. Our data collectively suggest that mf EV are enriched in miRNAs that regulate mTOR; studies with miRNA inhibitors in mf EV-exposed human DC are ongoing.

USING METABOLIC NETWORKS TO CHARACTERIZE THE SYMBIOSIS BETWEEN *WOLBACHIA* AND FILARIAL NEMATODES, AND IDENTIFY NOVEL DRUG TARGETS

Alexandra Grote[1], Dave Curran[2], Denis Voronin[3], Sara Lustigman[3], John Parkinson[2], Elodie Ghedin[1]

[1]New York University, New York, NY, United States, [2]Hospital for Sick Children, Toronto, ON, Canada, [3]New York Blood Center, New York, NY, United States

Filarial nematodes represent one of the leading causes of disability in the developing world. Many filarial worm species, including *Brugia malayi*, one of the causative agents of lymphatic filariasis, have an obligate endosymbiotic relationship with the alpha-proteobacteria *Wolbachia*. To better understand the molecular interplay between these two organisms, we profiled the transcriptomes of *B. malayi* and *Wolbachia* across the life cycle of the parasite using dual RNA-seq. This allowed us to pinpoint functional pathways that are putatively involved in this essential symbiotic relationship provided by the co-expression of nematode and bacterial genes. We are currently focusing on molting of the worm from L3 to L4, the molt which marks the establishment of infection in the human host and is characterized by a large expansion of the *Wolbachia* population. We have profiled the co-expressed pathways associated with molting as well as how those pathways are affected by either blocking molting of the worm or blocking bacterial expansion. In parallel, we used these transcriptomic data in combination with genomic data to characterize the endosymbiotic relationship at the metabolic level using Flux Balance Analysis to identify choke points that could be exploited for therapy. To better inform our metabolic model, we have also profiled the metabolome of both *Brugia malayi* and *Wolbachia* over the life cycle of the worm. By creating a draft metabolic network for *B. malayi* and *Wolbachia*, and using *in silico* knockouts, we have identified pathways that are possibly necessary for development and fitness and examined how these pathways are influenced by the presence of *Wolbachia*. These predictions are now being tested using RNAi and small molecule inhibitors in order to validate those that can be further developed as novel drug targets.

TRIATOMINE VECTORS, *TRYPANOSOMA CRUZI* STRAINS, AND CARDIAC ABNORMALITIES ASSOCIATED WITH NATURALLY-INFECTED DOGS ACROSS THE US

Alyssa C. Meyers[1], Julia Purnell[1], Megan Ellis[2], Lisa Auckland[1], Marvin Meinders[3], John Sanders[3], Ashley Saunders[1], Sarah Hamer[1]

[1]Texas A&M University, College Station, TX, United States, [2]Colorado State University, Fort Collins, CO, United States, [3]Department of Homeland Security, Washington, DC, United States

In the southern US, triatomine vectors maintain *Trypanosoma cruzi* in sylvatic cycles with occasional spillover to humans. Infection with *T. cruzi* may be asymptomatic or lead to heart disease and death in humans and animals, with no identified prognostic markers. We analyzed the relationships between markers of exposure, circulating parasite infection, strain type, and cardiac abnormalities in populations of naturally-infected dogs. Additionally, we collected triatomine vectors from the canine's environment. Given that dogs can serve as sentinels of human risk, knowledge of locally-circulating strains is critical from a one health perspective. The Department of Homeland Security trains thousands of working dogs to provide security functions nationwide; the high level of outdoor exposure of these dogs makes them an ideal study system for vector-borne diseases. In 2015-17, we sampled 1,660 working dogs from 43 states using indirect fluorescent antibody tests and immunochromatographic assays to detect an overall anti-*T. cruzi* antibody prevalence of 7.3% (CI: 6.1-8.6%). RT-PCR detected parasite DNA in three canine blood samples (0.2%), including strain type TcI and TcIV. Two species of triatomine (n=75) collected from canine environments showed 49.3% infection prevalence (16:8:6 ratio of TcI:TcIV:mixed TcI/TcIV), and molecular bloodmeal analysis (n=13) revealed vector feeding on dogs, wildlife, and humans. We applied 24-hour, ambulatory ECG monitors to 24 *T. cruzi*-infected and 18 uninfected dogs and measured serum concentrations of cardiac Troponin I (cTnI), a biomarker of cardiac injury. We found that 75% of seropositive and 5.6% of seronegative dogs had one or more ECG abnormalities (p<0.001). Further, the average cTnI levels of seropositive dogs (0.071 ng/mL) was significantly higher than those of the seronegative dogs (0.017 ng/mL, p=0.015), indicating that cardiac injury was more severe in positive dogs. Understanding the epidemiology of *T. cruzi* infection could not only assist canine health, but also assist in protecting human health.

GENDER BIAS IN VISCERAL LEISHMANIASIS: NATURE OR NURTURE?

Kristien Cloots[1], Sakib Burza[2], Paritosh Malaviya[3], Epco Hasker[1], Sangeeta Kansal[3], Jaya Chakravarty[3], Shyam Sundar[3], Marleen Boelaert[1]

[1]Institute of Tropical Medicine Antwerp, Antwerp, Belgium, [2]Médecins Sans Frontières, New Delhi, India, [3]Institute of Medical Sciences, Varanasi, India

Visceral leishmaniasis (VL) is a parasitic disease which is fatal if not treated timely. Gender bias leading to unfavorable clinical outcomes in women has been documented earlier in Bangladesh. Barriers to access health care for women are also a factor in India and Nepal, where a majority of patients that are diagnosed with VL are male. However, our hypothesis is that this gender difference is not totally explained by discrimination of women but also attributable to biological factors that make males more vulnerable to VL. We triangulated multiple data sources to compute VL incidence rates by gender in the region. First, we analyzed the official VL

case data collected through the government reporting system of India and Nepal between 2014-2017. Secondly, we exploited population-based data sets obtained in two longitudinal studies (1. Kalanet and 2. Health & Demographic Surveillance System in Bihar, India). Both data sets are based on an exhaustive household census and include data on seroconversion in antibody tests to *L.donovani* as well as VL incidence based on active house-to-house surveys, minimizing hence the gender difference in access to diagnosis and underreporting. Routine health system data show that men have an overall VL incidence rate which is almost twice that of women (female/male Incidence Rate Ratio (IRR) is 0.67 in India and 0.48 in Nepal). This difference becomes progressively more important after the age of 15 years and further increases with age. In the population-based cohort data VL incidence rates for women are 40% lower than those of men (IRR 0.57 after controlling for age group and study site – 95% CI 0.40-0.81). This study shows that the gender differences observed in VL case load cannot be explained entirely through a gender difference in access to health care alone, as in the demographic surveillance site underreporting was not an issue. Differences in exposure could partly explain findings (analysis in progress). However, the increasing gender difference in VL incidence after the age of puberty seems to suggest a major role for other biological factors such as sex hormones in the development of this disease.

QRS SCORE DISTRIBUTION AMONG CHAGAS CARDIOMYOPATHY PATIENTS OF VARIOUS SEVERITIES

Brandon Mercado[1], Virginia Cooper[2], Paula Carballo[3], Freddy Tinajeros[2], Edith Malaga[1], Lola Telleria[3], Gustavo Duran[4], Margot Duran[3], Marcelo Cuellar[5], Daniel Alyesmerni[3], Raquel Marcus[3], Manuela Verastegui[1], Caryn Bern[6], Robert H Gilman[2]

[1]Infectious Diseases Research Laboratory, Department of Cellular and Molecular Sciences, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Department of International Health, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, United States, [3]A.B Prisma, Santa Cruz, Plurinational State of Bolivia, [4]San Juan de DIos Hospital, Santa Cruz, Plurinational State of Bolivia, [5]San Juan de Dios Hospital, Santa Cruz, Plurinational State of Bolivia, [6]Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA, United States

Chagas is a neglected tropical disease caused by the parasite *Trypanosoma cruzi,* and is responsible for a large amount of morbidity and mortality in Latin America. Chagas cardiomyopathy is the most severe effect of Chagas disease and is seen in 20-30% of infections. Early diagnosis and treatment have been shown to reduce morbidity and mortality. Previous studies have shown a relationship, in Chagas patients, between cardiac severity and their QRS score, determining myocardial scar size however, this distribution has yet to be compared to that of non-Chagas. We conducted a cross-sectional analysis from a cohort study, in a public hospital in Santa Cruz, Bolivia. Participants who tested positive by at least two assays were considered to have Chagas. QRS scores were determined for each subject by measuring amplitude and duration of Q, R and S waves on the EKG reading. Subjects were classified by cardiomyopathy progression (Stages A, B, C, or D) based on their results on an echocardiogram. The population consisted of 1071 patients, where the prevalence of Chagas was 89%, mostly women. Cardiac severity distribution, in the entire population, shows that stages A and B are more prevalent. The QRS score median in Chagas patients is 2.6 which was not statistically different from non-Chagas patients. No significant differences were observed between the median QRS scores in the non-Chagas patients, within any specific cardiomyopathy severity stage; however, within the Chagas patients, QRS scores increased with progression of cardiomyopathy severity, with significant differences occurring between Stage A and Stages B, C, and D, as well as between Stage B and Stages C and D. Interestingly, QRS score across cardiac disease severity in Chagas patients differs from non-Chagas patients. The median QRS scores increases in Chagas patients by one point across each stage compared to non-Chagas patients where the median scores increased by one point only between A to B. Since QRS score can be statistically different across cardiac severity, it could be used as an inexpensive method of diagnosis in lower income countries where access to echocardiograms is limited.

IGG SUBCLASSES AND CONGENITAL TRANSMISSION OF CHAGAS DISEASE

Cristian Roca[1], Edith S. Malaga[1], Billy H. Scola[2], Manuela R. Verastegui[1], Edward Valencia[1], Maria del Carmen Menduiña[3], Natalie Bowman[4], Freddy Tinajeros[2], Robert H. Gilman[5], Working Group Congenital Chagas[2]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Asociacion Benefica PRISMA, Lima, Peru, [3]Maternity Hospital, Santa Cruz, Plurinational State of Bolivia, [4]North Carolina University, North Carolina, NC, United States, [5]Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States

Chagas disease is a neglected tropical disease caused by *Trypanosoma cruzi*. Tropical areas with high poverty have higher rates of *T. cruzi* infection. Bolivia has the highest rates of Chagas disease in the world. The mechanism of vertical transmission is poorly understood. In this study, we evaluated IgG subclasses in Chagas-seropositive population in order to find an associated factor that helps us to predict the congenital transmission of Chagas disease. A case-control study was conducted in a public hospital in Santa Cruz, Bolivia. A total of 89 Chagas-positive, pregnant women at day of birth were included. Among these, the case group included 30 mothers who transmitted Chagas to their newborn and the control group included 59 mothers who did not transmit Chagas. ELISA was standardized in order to evaluate Chagas-specific IgG1, IgG2a, IgG3 and IgG 4 levels. Quantitative PCR results and demographic factors were also measured. IgG1 levels were 2.27 times higher in the mothers who transmit Chagas disease ($P < 0.01$), 44% higher values of IgG2a involved in congenital transmission ($P < 0.01$), 7.89 times higher in parasitemia mothers ($P < 0.01$), and 79% lower in mothers who had recently received a blood transfusion ($P = 0.05$). However, IgG3 was not associated with congenital transmission and IgG4 was unmeasurable. We therefore demonstrate that IgG subclasses and parasitic load are important factors associated with the congenital transmission of Chagas disease and thus has the potential for future use in screening for mothers at high risk for transmission of Chagas to their newborn.

COMPARISON OF TWO APPROACHES TO ACTIVE CASE FINDING OF SLEEPING SICKNESS IN TWO DISTRICTS IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Yves Claeys[1], Alain Mpanya[2], Rian Snijders[1], Alain Fukinsia[2], Marleen Boelaert[1], Erick Miaka[2], Epco Hasker[1]

[1]Institute of Tropical Medicine Antwerp, Antwerp, Belgium, [2]Programme National de Lutte contre la Trypanosomiase Humaine Africaine, Kinshasa, Democratic Republic of the Congo

As the number of Human African Trypanosomiasis (HAT) cases is steadily declining over the past decade through intensive active screening campaigns in endemic areas, the elimination as a public health problem of this deadly disease now appears within reach. In the Democratic Republic of the Congo (DRC), several endemic HAT pockets remain though, where the elimination target has not been achieved yet. As elimination efforts are stepped up, reaching those most at risk with the screening program becomes increasingly important. In two health districts in DRC, we have compared the uptake of a traditional approach of mass screening (truck-based teams) with an innovative approach of door-to-door screening with so-called 'mini teams.' Data was captured through a mobile application. We recorded demographic data as well as results of diagnostic tests. We analyzed the sex- and age distribution of people screened in each approach and compared these "population pyramids" to the age and gender distribution of HAT cases recorded

by the national HAT Control Program. The sex-and age pyramid of the population screened show that the young adults (between 20-40 years), and mainly men, are underrepresented. The age and gender distribution of documented HAT cases show that these are the groups most at risk. The underrepresentation of young adults is much less pronounced in the output data obtained from the mini-teams. The door-to-door approach of the mini-teams appears to have a positive influence on the coverage of the people most at risk (adults between 20 and 40). We assume they participate more readily because of reduced waiting times and lesser opportunity costs when screening is done by door-to-door home visits.

1471

DISTRIBUTION AND ENVIRONMENTAL RISK FACTORS ASSOCIATED TO CHAGAS CARDIOMYOPATHY IN BOLIVIA

Brandon Mercado[1], Ximena Porcasi[2], Monica Pacoricona[3], Virginia Cooper[4], Paula Carballo[5], Freddy Tinajeros[4], Lola Telleria[5], Gustavo Duran[5], Edith Malaga[1], Eliana Saenza[5], Jorge Flores[5], Raquel Marcus[5], Daniel Alyesmerni[5], Manuela Verastegui[1], Caryn Bern[6], Robert H Gilman[4]

[1]Infectious Diseases Research Laboratory, Department of Cellular and Molecular Sciences, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Department of Epidemiology and Spatial application, CONAE, Cordoba, Argentina, [3]Ministry of Health, Cochabamba, Plurinational State of Bolivia, [4]Department of International Health, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, United States, [5]A.B Prisma, Santa Cruz, Plurinational State of Bolivia, [6]Department of Epidemiology and Biostatistics, University of California—San Francisco, San Francisco, CA, United States

Chagas disease is a neglected tropical disease caused by *Trypanosoma* cruzi that produces a high rate of morbidity throughout Latin America. In 2015, one study showed that the prevalence among adults in rural Bolivia was up to 80%. In 20-30% of the cases, Chagas progresses into cardiomyopathy with high rates of mortality. The distribution and associated factors of Chagas cardiomyopathy are not yet well understood in Bolivia, where the rates of mortality are highest. Early diagnosis and treatment can mitigate the risk of death caused by this disease. We conducted a cross-sectional analysis from a cohort study, in a public hospital in Santa Cruz, Bolivia. Participants underwent three serological tests for Chagas; patients who tested positive on at least two assays were considered to have Chagas. Echocardiography was used to classify cardiomyopathy progression from stage A to the final stage D. Geographic information system (GIS) was used to find distribution among stages of cardiomyopathy. Environmental information was used to evaluate risk factors, such as ecological changes, altitude, normalized difference vegetation index, presence of vector and incidence rate per community. The population consisted of 1,117 patients, 97% of which are stages A and B. We compared the distribution of cases across Bolivia with incidence rate per community, finding a significant association. Cardiomyopathy stages A and B had the same distribution across Bolivia regardless of incidence rate. However, stages C and D were significantly distributed only in communities with a medium and high incidence rate. Altitude, use of land and presence of the vector were significant associated to the progression of Chagas cardiomyopathy. Chagas cardiomyopathy distribution and future environmental changes measured by serial GIS can be used to help predict emerging regions at high-risk for advanced cardiomyopathy. Early detection could help reduce morbidity and mortality rates caused by Chagas disease.

1472

IMPACT OF HOUSING COMPOSITION ON DOMESTIC TRIATOMINE EXPOSURE RISK: EPIDEMIOLOGIC INVESTIGATION IN WEST TEXAS REGION ALONG THE UNITED STATES - MEXICO BORDER

Rodion Gorchakov[1], Sarah M. Gunter[1], Kyndall Dye-Braumuller[2], Rebecca M. Berry[1], Raymond Skiles[3], Kristy O. Murray[1], Melissa S. Nolan[1]

[1]Baylor College of Medicine and Texas Children's Hospital, Houston, TX, United States, [2]Harris County Public Health, Houston, TX, United States, [3]National Park Service, Big Bend National Park, TX, United States

Residents of Trans-Pecos region of west Texas along the U.S. - Mexico border have reported a high rate of exposure to bites of triatomine insects, or kissing bugs - the vectors of Chagas disease (*Trypanosoma cruzi* infection). We performed an epidemiologic investigation into the potential for *T. cruzi* vector-borne transmission resulting in human disease in this area of Texas. Residential assessments included housing conditions, socio-economic and environmental factors, and vector evaluation. We enrolled 85 participants residing in either Terlingua, TX or the Panther Junction area of Big Bend National Park (BBNP), and tested them for antibodies against *T. cruzi*. Residents of 55 homes completed self-reported house infestation questionnaire, with 85% (47 out of 55) documenting history of triatomine bites. Fourteen homes were inspected by our study team revealing considerable variance in home structures, which is believed to be associated with increased triatomine exposure. Kissing bugs, predominantly *Triatoma rubida*, were collected by active surveillance and by citizens submissions from three distinct locations: Terlingua, Panther Junction area, and a nearby K-Bar station at the BBNP. *T. cruzi* DNA was detected in 32 out of 88 triatomines (36%), and proportion of positive insects ranged from 0 to 68%, depending on the collection location. Parasites from all 32 positive kissing bugs were determined to belong to discrete typing unit I genotype. While all of the study participants tested negative for *T. cruzi* antibodies, reports of frequent exposures to triatomines, in combination with presence of *T. cruzi*-positive insects, indicates a risk for acquiring *T. cruzi* infection exists in the investigated area.

1473

IMPACT OF EXTRINSIC INCUBATION TEMPERATURE ON ZIKA VIRUS POPULATION DIVERSITY IN *AEDES* MOSQUITOES

Reyes Murrieta, Selene Garcia-Luna, Claudia Rückert, Gareth Halladay, James Weger-Lucarelli, Joseph Fauver, Alex Gendernalik, Deedra Murrieta, Michael Young, Gregory Ebel

Colorado State University, Fort Collins, CO, United States

Arthropod-borne viruses (arboviruses) continue to emerge as major threats to public health. In part, the process of arbovirus emergence has been driven by the emergence of new virus genotypes that alter key transmission phenotypes. The conditions that lead to new virus genotypes are, however, not fully understood. Accordingly, we sought to (1) define the impact of temperature on transmission dynamics of ZIKV and (2) determine whether temperature affects virus population structure during extrinsic incubation (EI) in the mosquito. In particular, we exposed *Aedes aegypti* and *Aedes albopictus* mosquitoes to a bloodmeal containing a Puerto-Rican strain of Zika virus and held them for 7 and 14 days at 25°C, 28°C and 35°C. We also exposed them to fluctuating temperatures that varied from 25-35°C diurnally. We found that transmission of ZIKV in both *Aedes* mosquitoes is most efficient at 28°C (P-value <0.05). However, viral load in the midgut and hemolymph of these mosquitoes is highest at 35°C (P-value <0.05). Using RNAseq to characterize virus genetic diversity, we have identified two consensus changes found in both *Aedes* mosquitoes associated with high temperature (28°C & 35°C) and show that EI temperature increases, so does the number of consensus changes to the ZIKV genome (25°C = 7, 28°C = 20, 25°C-35°C = 14, & 35°C =

18). We then assess the variant frequency during systemic ZIKV infection of four minority variants (frequency of 0.12-0.35) found in the input ZIKV population, and show that there are temperature and mosquito dependent affects to intrahost variant frequency. Last, we use population genetics analysis to investigate how the intrahost ZIKV population diversity in *Aedes* mosquitoes is shaped by the EI temperature. Collectively, our data indicate that temperature has multiple impacts on ZIKV biology within mosquitoes.

1474

INTRAHOST DIVERSITY OF ZIKA VIRUS IN BLOOD, URINE AND SALIVA OVER TIME IN AN INDEX CLUSTER STUDY IN NICARAGUA

October Michael Sessions[1], Raquel Burger-Calderon[2], Paola Florez de Sessions[3], Collins Wenhan Chu[3], Andreas Wilm[3], Rachel Phu[4], Eliza Ho[3], Xin Mei Ong[1], Guillermina Kuan[5], Angel Balmaseda[6], Eng Eong Ooi[1], Eva Harris[2]

*[1]Duke-Nus, Singapore, Singapore, [2]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, [3]Genome Institute of Singapore, A*STAR, Singapore, Singapore, [4]School of Biological Sciences, Nanyang Technological University, Singapore, Singapore, [5]Health Center Sócrates Flores Vivas, Ministry of Health, Managua, Nicaragua, [6]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministry of Health, Managua, Nicaragua*

The Americas recently experienced a major epidemic of Zika virus (ZIKV) infections that have been linked to congenital birth defects and Guillain-Barré Syndrome. To better understand the mechanisms underlying the persistence of this virus in human bodily fluids, a longitudinal study was conducted from August 31 to October 21, 2016, in Managua, Nicaragua. We enrolled 33 RT-PCR-confirmed Zika index cases and their household members (109 contacts) and collected samples on days 0-1, 3-4, 6-7, 9-10, and 21, collecting serum/plasma, urine and saliva specimens. In order to glean as much information as possible about viral genetics from this cohort, we used a novel viral RNA enrichment strategy coupled with Next Generation Sequencing (NGS) that functions without any a priori assumptions about the target genome. This hybridization-based enrichment strategy, consisting of ZIKV-specific 120-nt, biotinylated oligodeoxynucleotides to capture ZIKV genomic material, addresses the principal problem encountered when employing NGS directly on patient samples; namely, the high ratio of host to viral RNA. The strategy developed here allowed us to enrich ZIKV genomic material over 5,000-fold relative to unenriched material. Importantly, by sequencing directly from the sera/plasma, urine and saliva of the infected subjects, we were able to measure the intrahost genetic diversity of the virus in each fluid type. Our ongoing study has utilized the viral variant data to assemble probable haplotypes emerging within each of these compartments and characterized the evolution of these haplotypes over time. Our results indicate that over the course of an infection in a single person, there is variation between compartments and over time. Given that current molecular epidemiology is based on the viral sequences derived from blood and urine interchangeably, we suggest that this compartment-based genomic diversity needs to be taken into consideration.

1475

A ZIKA VIRUS MUTATION THAT ASSOCIATES WITH FETAL DEATH IN RHESUS MACAQUES REDUCES TRANSMISSION BY *AEDES AEGYPTI* MOSQUITOES

Danilo E. Lemos[1], Nathan D. Grubaugh[2], Anil Singapuri[1], Konstantin Tsetsarkin[3], Koen K. Van Rompay[4], Charles Y. Chiu[5], Kristian G. Andersen[2], Lark L. Coffey[1]

[1]University of California, Davis, School of Veterinary Medicine, Davis, CA, United States, [2]The Scripps Research Institute, San Diego, CA, United States, [3]National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [4]University of California, Davis, California National Primate Research Center, Davis, CA, United States, [5]University of California, San Francisco, School of Medicine, San Francisco, CA, United States

Fetal microcephaly and death are now recognized as severe forms of congenital Zika syndrome; however, it is still unclear whether recent Zika virus (ZIKV) mutations contribute to this phenotype. We identified a single intra-host variant in the ZIKV NS2B protein (NS2B^{M1404I}) from a rhesus macaque (RM) fetus that died after experimental ZIKV inoculation in the first trimester. Targeted deep sequencing flanking NS2B^{1404} in subsequent cohorts of RM mothers and their fetuses identified NS2B^{M1404I} at minority frequency and sometimes at consensus levels in 100% (7/7) of dead or stillborn RM fetuses and/or the plasma of their mothers and in 26% (4/15) of RM mother and fetus pairs whose fetuses survived to near term or were born alive. By examining sequence data from recent epidemics, we found that NS2B^{M1404I} occurs rarely (5/500, 1%) in consensus human ZIKV genomes. We also deep sequenced ZIKV genomes from non-pregnant human adults, infants, and *Aedes aegypti* from the epidemic and observed that NS2B^{I1404} was more often present at intra-host levels in humans compared to mosquitoes. Since the primary ZIKV transmission cycle is human-mosquito-human, viral mutations that arise in one host must be maintained in the alternate host to be perpetuated. We therefore hypothesized that ZIKV NS2B^{M1404I} may not be efficiently transmitted by *Aedes aegypti* mosquitoes, explaining its low frequency in humans during outbreaks. We engineered NS2B^{M1404I} into a ZIKV infectious clone and examined vector competence in *Ae. aegypti* from Puerto Rico. Although infection and dissemination rates were not different, we found that Ae. *aegypti* did not transmit ZIKV-NS2B^{I1404} as efficiently compared to ZIKV-NS2B^{M1404} 5 [7/20 (35%) versus 10/20 (50%), p>0.05] and 7 [3/20 (15%) versus 13/20 (65%), P<0.001, Chi-squared] days post-feed. The poor transmissibility of this potentially human/primate adaptive ZIKV mutation identified here may explain its low frequency in febrile humans. Furthermore, our data highlights the evolutionary complexity during arbovirus transmission cycles and suggests that some pathogenic mutations are not likely to spread in epidemics.

INTERNATIONAL TRAVELERS AND VIRUS GENOMES REVEAL 'HIDDEN' ZIKA VIRUS TRANSMISSION DURING THE EPIDEMIC

Nathan D. Grubaugh[1], Sharada Saraf[2], Amanda L. Tan[3], Karthik Gangavarapu[2], Andrea Morrison[4], Danielle Stanek[4], Blake Scott[4], Kirtana Ramadugu[4], Vanessa Landis[4], Alexander Watts[5], Michael Wiley[6], Stephen White[4], Karla Prieto[6], Glenn Oliveira[2], Nathaniel L. Matteson[2], Gustavo Palacios[6], Lauren Gardner[7], Kamran Khan[5], Jason T. Ladner[8], Sharon Isern[3], Scott F. Michael[3], Kristian G. Andersen[2]

[1]Yale University, New Haven, CT, United States, [2]The Scripps Research Institute, San Diego, CA, United States, [3]Florida Gulf Coast University, Fort Myers, FL, United States, [4]Florida Department of Health, Miami, FL, United States, [5]St. Michael's Hospital, Toronto, ON, Canada, [6]US Army Research Institute of Infectious Diseases, Frederick, MD, United States, [7]University of New South Wales, Sydney, Australia, [8]Northern Arizona University, Flagstaff, AZ, United States

The recent Zika virus disease epidemic in the Americas was unprecedented in both its scale and severity. Despite the attention that the epidemic drew, we still do not have a very accurate accounting of its emergence patterns. Specifically, we previously identified significant temporal surveillance gaps between the true introduction of the virus and its first detection within a region. There are likely many reasons for this gap, which may include (1) overlapping symptoms between Zika virus and other viruses, (2) its rapid spread, and (3) the fact that low income areas were often hit the hardest. One mechanism to help alleviate this reporting problem is to monitor the millions of returning US travelers who visited these regions during the epidemic. We used international travel-associated Zika virus infections reported by the Florida Department of Health and air travel

volumes to calculate travel incidence rates when coming from a specific region. We found a strong correlation between the travel incidence rates and local reported rates when there was a high travel volume from the region and consistent local reporting. From some regions with inconsistent local reporting but high travel volumes, our data suggests that there was undetected or unreported Zika virus transmission extending into 2017, when the epidemic was believed to be waning. To further investigate these transmission patterns, we sequenced Zika virus genomes from infected travelers. Our data from Cuba, for example, suggest that (1) Zika virus entered the country multiple times during 2016, when transmission was at its peak in nearby regions, which (2) resulted in a large unreported outbreak in 2017. Overall, we demonstrate how infection patterns of international travelers can help to reveal 'hidden' outbreaks and that Zika virus transmission may be still occurring in underreported regions.

ZIKA VIRUS OF BOTH AFRICAN AND ASIAN LINEAGES CAUSE FETAL HARM IN A VERTICAL TRANSMISSION MODEL

Anna S. Jaeger[1], Reyes M. Murrieta[2], Heather A. Simmons[1], Andres Mejia[1], Michael Fritsch[1], Lea Goren[1], Gregory D. Ebel[2], Thomas C. Friedrich[1], Matthew T. Aliota[1]

[1]University of Wisconsin Madison, Madison, WI, United States, [2]Colorado State University, Fort Collins, CO, United States

Congenital Zika virus (ZIKV) infection was first linked to birth defects during the American outbreak. It is not clear whether American isolates are unique in their ability to cause congenital Zika syndrome (CZS), but some genetic mutations unique to the American-lineage have been proposed to explain, at least in part, the ability of American ZIKV to cause CZS. Recent studies identified a number of mutations in ZIKV infecting humans that arose around the time of the outbreak in French Polynesia and were stably maintained during subsequent spread to the Americas. Some of these mutations have been proposed to contribute to the sequelae associated with ZIKV infection during pregnancy. For example, it has been postulated that a single amino acid substitution identified in the transmembrane protein (prM; S139N) in American-lineage viruses may play a key role in the development of microcephaly. However, the functional role of this mutation has not been evaluated using a natural vertical transmission model. We engineered the reverse mutation (N139S) into the Puerto Rican ZIKV isolate PRVABC59 genome and evaluated its capacity to cause pathogenic outcomes in pregnant mice lacking type I interferon signaling (*Ifnar1-/-*). *Ifnar1-/-* females were crossed to wild type males to produce heterozygous fetuses to resemble the immune status of human fetuses. Maternal inoculation with 10^3 PFU of ZIKV-N139S (mutant) or ZIKV-S139N (wildtype) at embryonic day 6.5 (E6.5) both resulted in fetal demise and severe intrauterine growth restriction (IUGR). We also inoculated dams at E6.5 with 10^3 PFU of the low-passage West African isolate Dakar 41524 (ZIKV-DAK). Infection with ZIKV-DAK resulted in overt clinical signs for the dams, as well as fetal demise, reduced litter size, and severe IUGR. Collectively, our data suggest that ZIKV's capacity to infect and harm the fetus existed prior to the American outbreak. These preliminary results highlight the need to better understand the pathogenicity of Zika viruses circulating in both Africa and southeast Asia.

ANTI-ZIKA VIRUS ANTIBODIES MODULATE VIRUS TRANSPORT ACROSS PLACENTAL CELL MONOLAYERS AND SUBSEQUENT INFECTION OF FC-GAMMA RECEPTOR-BEARING CELLS

Milena Dimitrova[1], Henry Puerta-Guardo[1], Takako Tabata[2], Matthew Pettit[2], Chunling Wang[1], Davide Corti[3], Lenore Pereira[2], Eva Harris[1]

[1]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, [2]Department of Cell and Tissue Biology, School of Dentistry, University of California San Francisco, San Francisco, CA, United States, [3]Humabs SA, a subsidiary of Vir Biotechnology, Bellinzona, Switzerland

Zika virus (ZIKV) is a mosquito-borne flavivirus that caused major epidemics throughout the Americas in 2015-2016, and ZIKV infection during pregnancy has been associated with devastating fetal birth defects. The placenta separates maternal circulation from the developing fetus and is the site at which maternal antibodies are transported to the fetal blood stream. Here, we are studying the role of anti-ZIKV antibodies in facilitating virus transport into human placental tissues and in modulating infection of cells in anchoring chorionic villus explants. Briefly, ZIKV alone or in the presence of anti-ZIKV monoclonal antibodies (mAbs) as immune complexes (ICs) were added to the apical side of cultured human chorionic trophoblast (JAR) and umbilical vein endothelial cell monolayers in a transwell system. Then, the amount of free ZIKV and ZIKV-ICs collected in the basolateral chamber of transwells was separated and quantified by qRT-PCR after a protein G-agarose pull-down. We found that low levels of free ZIKV crossed through polarized placental cell monolayers in the absence of antibodies, but the presence of anti-ZIKV mAbs resulted in greater transport of virions in the form of ICs. We show that ZIKV that crosses these cell monolayers infects human monocytic U937 cells expressing the attachment factor DC-SIGN plated in basolateral chambers. We also show that certain anti-ZIKV mAbs directed to the E protein can either neutralize or enhance infection of cells in the basolateral compartment. Ongoing experiments are using ZIKV-specific mAbs and anti-ZIKV mAbs that are cross-reactive to the related dengue virus with either high and low neutralizing potency to understand the role of antibodies in mediating neutralization or enhancement of FcγR-expressing cells in the basolateral chamber after transport across placental cell monolayers. Additionally, we are studying ZIKV infection of fetal macrophages and other cells in the presence and absence of anti-ZIKV antibodies in human *ex vivo* anchoring villus explants. Overall, these studies should improve our understanding of the role of maternal antibodies in ZIKV dissemination during gestation.

Oliveira[5], Edison L. Durigon[5], Daniele F. Henriques[6], Pedro F. Vasconcelos[6], Nikos Vasilakis[7], Antonio R. Almeida[1], Mitermayer G. Reis[3], Albert I. Ko[2]

[1]Federal University of Bahia, Salvador, Brazil, [2]Yale School of Public Health, New Haven, CT, United States, [3]Oswaldo Cruz Foundation, Brazilian Ministry of Health, Salvador, Brazil, [4]Hospital Geral Roberto Santos, Salvador, Brazil, [5]University of São Paulo, São Paulo, Brazil, [6]Evandro Chagas Institute, Ananindeua, Brazil, [7]University of Texas Medical Branch, Galveston, TX, United States

It remains unknown whether the presence of antibodies to DENV virus confer resistance or susceptibility to clinical outcomes of Zika virus (ZIKV) infection. We performed a case-control investigation to determine whether maternal DENV neutralizing antibodies were associated with acquisition of congenital Zika syndrome-associated (CZS) microcephaly among infants whose mothers had serological evidence of ZIKV exposure. Active surveillance identified infants with CZS microcephaly, defined as head circumference <-2 SD and clinico-radiological findings, among live births at a maternity hospital in Salvador, Brazil between November 2015 to January 2016. We determined plaque reduction neutralization titers (PRNT) to ZIKV and DENV serotypes for sera from the mothers. Among infants of mothers who ZIKV neutralizing antibodies (PRNT ≥1:40), we selected case infants who had CZS microcephaly and control infants who did not have microcephaly and or had microcephaly without CZS criteria. Logistic regression analyses were performed to evaluate the independent

association of maternal DENV $PRNT_{90}$ and CZS microcephaly. Among 422 live births during the study period, 40 (9.4%) had CZS microcephaly. Among 36 mothers of infants with CZS microcephaly, 35 (97%) had ZIKV neutralizing antibodies, whereas 31 (56%) of 55 mothers of infants without CZS microcephaly had ZIKV neutralizing antibodies. Analysis of 35 case and 31 control infants identified female gender (OR 6.50, 95% CI 1.59-37.97) and ZIKV IgM in cord blood (OR 36.09, 95% CI, 7.06-308.90) as significant risk factors. High neutralizing titers (≥320) to DENV2 was independently associated with decreased risk (OR 0.16, 95% CI 0.02-0.84) for CZS microcephaly. In contrast low neutralizing titers (40-160) to DENV2 was associated with increased risk (4.97 (1.01-32.86) for CZS microcephaly. These findings indicate that the prior history of dengue exposure in mothers influences the risk of severe birth defects among their infants who were exposed to ZIKV *in utero*, and suggests that quantity of DENV antibodies contributes to either resistance or susceptibility to these outcomes.

1480

SAFETY, IMMUNOGENICITY AND EFFICACY OF THE FIRST INJECTABLE, GENETICALLY ENGINEERED MALARIA VACCINE PFSPZ-GA1 VACCINE

Meta Roestenberg

PfSPZ-GA1 Consortium, Leiden, Nijmegen, Netherlands

Immunization of adults with radiation- or chemo-attenuated *Plasmodium falciparum* (Pf) sporozoites (SPZ) (Sanaria® PfSPZ Vaccine or PfSPZ-CVac) has shown to protect >90% of vaccinees against controlled human malaria infection (CHMI) and to protect against naturally transmitted Pf in Africa for at least 6 months. Genetically engineered PfSPZ have potentially improved safety and potency, and consequently significant costs of goods savings. We engineered genetically attenuated rodent and human malaria parasites by deleting two genes (Δ*slarp*Δ*b9*) and have demonstrated full attenuation in rodents, primary human hepatocytes and humanized mice. In addition, mice can be protected from challenge after repeated immunizations. PfΔ*slarp*Δ*b9* PfSPZ (Sanaria® PfSPZ-GA1 Vaccine) was manufactured in compliance with current Good Manufacturing Practices and released for human trials in the EU under a conditional release GMO license. In a dose escalating phase 1 clinical trial, the vaccine demonstrated an excellent safety profile, administered as single doses of 1.35x10e5, 4.5x10e5 and 9.0x10e5 sporozoites (n=3, 3 and 13 subjects respectively). All adverse events related to the vaccine were mild (grade 1). Diagnostic Pf PCR was performed on blood samples collected every day from day 6-21 and on day 28 after immunization and all were negative, indicating full genetic attenuation. Forty-eight subjects were subsequently enrolled in a randomized double blind trail and receive three doses at 8 week intervals of either 9.0x10e5 or 4.5x10e5 PfSPZ-GA1 Vaccine, or 4.5x10e5 PfSPZ Vaccine or saline placebo. Again, the vaccine had an excellent safety profile and no breakthrough parasites were detected. Subjects underwent CHMI with 5 mosquito bites 3 weeks after final immunization. Efficacy results from this challenge phase will be presented. In conclusion, PfSPZ-GA1 Vaccine is the first injectable genetically attenuated malaria vaccine assessed in humans. The accomplishment to manufacture, obtain regulatory approval and demonstrate an excellent safety profile is unprecedented and holds a promise for PfSPZ vaccines with increased potency.

1481

SAFETY, FEASIBILITY AND EFFICACY OF RADIATION-ATTENUATED *PLASMODIUM FALCIPARUM* SPOROZOITE (PFSPZ) VACCINE ADMINISTERED BY DIRECT VENOUS INOCULATION IN A PHASE 2 TRIAL IN INFANTS IN WESTERN KENYA

Martina Oneko[1], Laura C. Steinhardt[2], Yego R. Cherop[1], Kephas O. Otieno[1], Tony Sang[1], Ryan E. Wiegand[2], Gail Potter[3], Dorcas Akach[1], Julie R. Gutman[2], Aaron M. Samuels[2], Simon Kariuki[1], Paul N. Oloo[1], Allan Dungani[1], Dennis K. Bii[1], Elizabeth L. Nzuu[1], Ginnie Abarbanell[4], David Styers[3], Adam J. Ruben[5], Kim L. Sim[5], Peter F. Billingsley[5], Patrick S. Kachur[2], Eric R. James[5], Thomas L. Richie[5], Stephen L. Hoffman[5], Robert A. Seder[6]

PfSPZ Vaccine is a pre-erythrocytic malaria vaccine composed of radiation-attenuated, aseptic, cryopreserved *Plasmodium falciparum* (Pf) sporozoites administered by direct venous inoculation (DVI). PfSPZ Vaccine showed vaccine efficacy (VE) of 60% for 14 months in malaria-naïve adults in the US against controlled human malaria infection and 52% by time-to-event and 29% by proportional analysis for 6 months against Pf infection by natural exposure in adults in Mali. To assess VE in Africans with less lifetime Pf exposure, we conducted a double-blind, placebo-controlled trial in 5–12-month-old infants in western Kenya. Infants were randomized 1:1:1:1 to receive 3 doses of 4.5, 9.0, or $18.0x10^5$ PfSPZ or placebo 8 weeks apart from January–August 2017; safety, feasibility, and VE against naturally transmitted Pf were assessed. Incident parasitemia was recorded during clinic and home visits for 6 months after last vaccination. 336 infants received 979 vaccinations, 95.2% by a single injection; 317 infants received all 3 vaccinations. There were no obvious safety signals in blinded safety data. 13.1% (2 Grade 3) and 9.2% (1 Grade 3) of infants had potentially related, solicited local and systemic adverse events (AEs) respectively during 7 days post vaccination. 37 unrelated serious AEs occurred in 35 infants. 58% of controls developed Pf infections during follow-up. Preliminary VE estimates by time-to-event analysis for Pf infection were 13% (95% CI: -32%, 43%), 2% (95% CI: -48%, 35%), and 32% (95% CI: -5%, 55%), in the 4.5, 9.0, and $18.0x10^5$ PfSPZ dose groups, respectively. VE by proportional analysis (any Pf infection vs. none) was 1% (95% CI: -27%, 22%), -7% (95% CI: -35%, 15%), and 13% (95% CI: -13%, 34%) respectively. Administration of PfSPZ Vaccine by DVI to Kenyan infants was safe and feasible; no VE results were significant at the $p<0.05$ level. Lower-than-expected VE may have reflected immunological immaturity, suggested by a recent study in Tanzania, in which infants immunized with PfSPZ Vaccine did not make significant T cell responses although older age groups did. Antibody and cellular immunological data from Kenya will also be presented.

1482

MODELLING THE RELATIVE ROLES OF ANTIBODY TITRE AND AVIDITY IN PROTECTION FROM *PLASMODIUM FALCIPARUM* INFECTION FOLLOWING RTS,S VACCINATION IN A HUMAN CHALLENGE STUDY

Hayley A. Thompson[1], Alexandra B. Hogan[1], Patrick G. Walker[1], Michael T. White[2], Aubrey J. Cunnington[1], Chris F. Ockenhouse[3], Azra C. Ghani[1]

[1]Imperial College London, London, United Kingdom, [2]Institute Pasteur, Paris, France, [3]PATH Malaria Vaccine Initiative, Washington, DC, United States

Vaccination with the RTS,S/AS01 pre-erythrocytic vaccine has previously been demonstrated to induce antibody titres shown to be associated with protection from infection in both challenge studies and subsequent Phase II and Phase III field trials. In a recent challenge study in which the immunisation schedule was altered by delaying the third dose by 5 months and delivering it at 20% of the full dose (delayed fractional dose, Fx017M), vaccine efficacy increased to 86.7% compared to 62.5% under the original dosing schedule in malaria naïve adults. There was no significant difference in antibody titres between the arms; however, the antibody avidity was significantly higher in the Fx017M arm. We extended an existing biologically motivated model of sporozoite infection to characterise how both antibody titre and antibody avidity relate to protection in this challenge study. The model was fitted to immune data from the 46 malaria naïve adults in the Fx017M study. We found that a model incorporating both antibody titre and avidity provided a better fit to the data than a model incorporating antibody titre alone. Categorising both antibody titre and avidity into three levels (low, medium, high) we estimate vaccine efficacy to be 94.2% in those with high titre and avidity, 76.9% in those with high avidity but low titre, 61.6% in those with low avidity and high titre and 38.3% in those with low avidity and low titre. Higher avidity levels were therefore found to be more important in protection than high antibody levels in these individuals, with high avidity required for protection across all but the highest antibody titres. This suggests that the quality of the induced antibody response is likely to be more important than the quantity alone in the development of highly efficacious pre-erythrocytic vaccines against malaria.

1483

TOWARDS GENERATING A GENETICALLY-ENGINEERED REPLICATION-COMPETENT WHOLE *PLASMODIUM FALCIPARUM* PARASITE VACCINE THAT CONFERS BROAD AND DURABLE PROTECTION AGAINST INFECTION

Debashree Goswami[1], Navinder K. Gurmit Singh[1], Sean C. Murphy[2], Ashley M. Vaughan[1], Stefan H. Kappe[1]

[1]Centre for Infectious Disease Research, Seattle, WA, United States, [2]Department of Laboratory Medicine, University of Washington, Seattle, WA, United States

Previous studies in models of rodent malaria provide conclusive evidence that a late liver stage-arresting genetically attenuated *Plasmodium* parasite (GAP) vaccine acts as a superior immunogen compared to one that arrests early in the liver, thereby laying the translational foundation for an efficacious late-arresting GAP vaccine against human malaria. Two such LA-GAP candidates include *plasmei2*, the *Plasmodium* ortholog of the eukaryotic RNA-binding protein (RBP) Mei2, and *lisp2* (liver specific protein 2), that are conserved across the *Plasmodium* species and exclusively transcribed in liver stages. We have previously shown that the *P. yoelii plasmei2$^-$/lisp2$^-$* (*Py plasmei2$^-$/lisp2$^-$*) double knockout (KO) parasite is a synthetic lethal that arrests late in liver development and immunizations with *Py plasmei2$^-$/lisp2$^-$* confer complete sterile protection against sporozoite challenge. Herein, we report for the first time the successful generation of a LA-GAP in *Plasmodium falciparum* by gene deletion of *Pf plasmei2*. We found that *Pf plasmei2* is dispensable for asexual blood stages, for gametocyte formation and for developmental stages in the mosquito vector. Infection of human liver-chimeric FRG huHep mice with *Pf plasmei2$^-$* sporozoites does not impair either initial liver stage invasion or growth in cell size late into liver stage development. However, *Pf plasmei2$^-$* KO liver stages have discernible defects in schizogony, and do not form exo-erythrocytic merozoites. When FRG-huHep mice infected with *Pf plasmei2$^-$* KO sporozoites were infused with human red blood cells (RBCs) on Day 7 after infection, they did not become blood stage patent, in contrast to all mice infected with WT NF54 sporozoites and subsequently infused with human RBCs that transitioned to blood stages. These results strongly qualify *Pf plasmei2$^-$* KO as a candidate for a late liver-stage arresting GAP vaccine. Characterization of the *Pf lisp2$^-$* single KO and *Pf plasmei2$^-$/lisp2$^-$* double KO are currently in progress. Generation of such a replication-competent late liver stage-arresting GAP is a significant leap towards generating an efficacious anti-malarial vaccine.

1484

EFFECT OF DELAYED AND FRACTIONAL DOSING ON THE TITERS, FINE SPECIFICITY, AVIDITY AND BIOLOGICAL ACTIVITY OF RHESUS ANTIBODIES AGAINST A CIRCUMSPOROZOITE PROTEIN BASED VACCINE FMP013

Sheetij Dutta[1], Alicia Cawlfield[1], Christopher J. Genito[1], Zoltan Beck[1], Alexis Bitzer[1], Elke Bergman Leitner[1], Robert V. Gerbasi[2], Xiaoyan Zou[2], Sri H. Hadiwidjojo[2], Norman C. Waters[1], Viseth Ngauy[1], Carl Alving[1], Gary E. Matyas[1]

[1]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]Naval Medical Research Center, Silver Spring, MD, United States

Circumsporozoite protein (CSP) is present on malaria parasite sporozoites, and it contains NANP)n repeats flanked by N-terminal and C-terminal regions. A vaccine containing repeat and C-terminal regions, RTS,S (GlaxoSmithkline), showed <50% efficacy against natural *P. falciparum* infection. We produced a nearly full-length CSP vaccine FMP013 and formulated it in a liposomal adjuvant ALFQ that contains immune-modulators 3D-PHAD^{TM} and QS21. Here we report Rhesus study results on safety, toxicology and immunogenicity of FMP013 + ALFQ. Five groups (n= 6) received three vaccinations on 0-1-2 or 0-1-6 month schedule. Local site reaction, blood count and serum chemistry data showed a mild fever, a transient increase in WBC and neutrophils and a rise in creatine kinase level; however these normalized by day-7 post vaccination. Overall, the vaccine was safe and very well tolerated. The repeat titers were highly dependent on antigen and adjuvant dose. Overall, the boosting profile of equivalent low antigen doses in full human dose of ALFQ, on a 0-1-2 month schedule, was most desirable for high titer. Increasing antigen or reducing adjuvant dose negatively impacted antibody boosting. Compared to identical doses, fractional 3rd dose on 0-1-6 or 0-1-2 month schedule showed less boosting of C-terminal and no boosting of repeat titers. A trend towards the fractional dose on 0-1-2 schedule inducing higher titer than the delayed fractional group was noted. Most importantly, delayed and fractional schedule significantly increased avidity and delayed boosting was found to be the key driver of higher avidity, not antigen fractionation. ALFQ induced a balanced Th1:Th2 type response in primates and purified IgG strongly inhibited sporozoite development *in vitro*. We reproduced and further elucidated the findings from a delayed and fractional dose regimen of RTS,S in humans. Together these observations strongly support the evaluation of the FMP013+ALFQ vaccine in humans.

Adhesion of *Plasmodium falciparum*-infected erythrocytes (PEs) to placental chondroitin-4-sulfate (CSA) has been linked to the severe placental malaria (PM) outcomes. Evidences strongly support the VAR2CSA variant surface antigen mediating PEs CSA-binding phenotype as the leading candidate for a PM vaccine. This study was conducted to assess the safety and immunogenicity of 3 different dosages (20µg, 50µg and 100µg) of the recombinant VAR2CSA protein (PRIMVAC), formulated with Alhydrogel or GLA-SE administered at days 0, 28 and 56 A randomized double-blind phase Ia/Ib dose-escalation vaccine trial was conducted in healthy adult women. Within 4 sequential cohorts, volunteers were randomized to 2 arms (PRIMVAC adjuvanted with Alhydrogel or GLA-SE) in the first phase conducted in France and then to 3 arms (PRIMVAC with Alhydrogel or GLA-SE or placebo) in Burkina Faso. Enrolled volunteers were observed for at least 1 hour following each vaccination then seen at 1 day and 7 days later for safety evaluations. Serious adverse events (SAE) were recorded throughout the study duration. Routine clinical laboratory safety analyses were performed prior first injection and at each subsequent visit. A total of 68 subjects were recruited in the four study cohorts No SAE was reported in any of the cohort A volunteers and enrolment in cohort B started. A Data Safety Monitoring Board (DSMB) reviewed the safety data for cohorts A (20µg) and B (50µg) before the trial was initiated in Burkina Faso. The DSMB also reviewed the safety data in Burkina to authorize the progression from the cohort C (50µg) to cohort D (100µg). Last vaccination of the last subject occurred in September 2017. This was the first placental malaria vaccine phase Ia/b clinical trial conducted in France and Burkina Faso. No serious adverse events have been recorded. Preliminary safety and immunogenicity results will be presented.

1486

TOLERABILITY, SAFETY AND PROTECTIVE EFFICACY OF DIRECT VENOUS INOCULATION OF CONDENSED VACCINATION REGIMEN OF PFSPZ VACCINE IN TANZANIAN ADULTS INCLUDING HIV INFECTED VOLUNTEERS

Said A. Jongo[1], Thomas L. Richie[2], Claudia A. Daubenberger[3], Peter F. Billingsley[2], Kamaka Kassimu[1], Gloria Nyaulingo[1], B. K. Sim[2], Saumu Ahmed[1], Florence A. Milando[1], Mohammed Rashid[1], Tobias Schindler[4], Anneth Tumbo[1], Thabit Athuman[1], Khalfan Kiure[1], Beatus Simon[1], Selina Aloyce[1], Ramla Rashid[1], Jescica Mfaume[1], Theresia Ngonyani[1], Bakary Mwalimu[1], Kathleen Walker[2], Sumana Chakravarty[2], Eric James[2], Maximillian Mpina[1], Ally Olotu[1], Marcel Tanner[3], Salim Abdulla[1], Stephen L. Hoffman[2]

[1]Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania, [2]Sanaria Inc., Rockville, MD, United States, [3]Swiss TPH, Basel, Switzerland, [4]Swiss TPH, Rockville, Switzerland

PfSPZ Vaccine, composed of radiation-attenuated (non-replicating), purified, cryopreserved *P. falciparum* (Pf) sporozoites (PfSPZ), has been extremely well tolerated and safe in adults, children and infants (5 to 12 months). In Tanzania, 6/6 healthy HIV-negative adults who received 3 doses of $9x10^5$ PfSPZ of PfSPZ Vaccine administered by direct venous inoculation (DVI) at 8 week intervals were completely protected against homologous controlled human malaria infection (CHMI) at 3-11 weeks after immunization (100% efficacy). In Malian adults under high malaria exposure, vaccine efficacy (VE) of 29% and 52% by proportional and time to event analysis respectively was demonstrated against naturally transmitted malaria. Despite these promising results higher VE is desired for more impact in the field. Recently, an accelerated vaccination schedule of 0, 2, 4, 6 days with a 16 week boost provided a better magnitude and duration of protection, including protection against heterologous CHMI, in malaria-naïve adults. As this vaccine is intended for mass vaccination programs (MVPs) the condensed schedule and higher efficacy would facilitate its deployment in the field. Furthermore MVPs would target the entire population including those who are HIV infected. For this reason, demonstrating safety in those living with HIV-1 infection (HIV positive) is an important objective to enable successful deployment of PfSPZ Vaccine in MVPs. The present trial in Tanzanian adults (18-35 years) will determine whether immunization with PfSPZ Vaccine will predispose HIV positive individuals to more severe adverse event profiles. Moreover, we will determine if immunization enhances the progression of HIV disease or conversely if HIV co-infection might adversely affect the immunogenicity of PfSPZ Vaccine and consequently its ability to protect against malaria. The trial began in February 2018 and is expected to end in July 2018. The complete un-blinded results of tolerability, safety, immunogenicity and protective efficacy of this condensed vaccination regimen with a single boost at 28 days and spectrum of HIV exposure status will be presented.

1487

HOMOLOGS OF HUMAN DENGUE-RESISTANCE GENES, FKBP1B AND ATCAY, CONFER ANTIVIRAL RESISTANCE IN *AEDES AEGYPTI* MOSQUITOES

Seokyoung Kang[1], Dongyoung Shin[2], Berlin Londono-Renteria[3], Mi Young Noh[4], Tonya M. Colpitts[5], Rhoel R. Dinglasan[1], Yeon Soo Han[4], Young S. Hong[6]

[1]University of Florida, Gainesville, FL, United States, [2]University of Florida, Vero Beach, FL, United States, [3]Kansas State University, Manhattan, KS, United States, [4]Chonnam National University, Gwangju, Republic of Korea, [5]Boston University, Boston, MA, United States, [6]Access Bio, Inc, Somerset, NJ, United States

Dengue virus (DENV) is transmitted by mosquitoes and is a major public health concern. While chemical and genetic mosquito control strategies have been at the forefront for controlling DENV transmission, the basic biology underpinning mosquito vector competence for DENV remains

poorly understood. The study of innate mosquito defense mechanisms against DENV have revealed crucial roles for Toll, IMD, Jak-STAT and RNAi pathways in mediating DENV dissemination in the mosquito. Often overlooked in such studies is the role of intrinsic cellular defense mechanisms that we hypothesize to work in concert with the classical immune pathways to effect organismal defense. Our understanding of the molecular interaction of DENV with mosquito host cells is limited and we propose to expand upon the recent results from a human cell line study. A comprehensive genome-scale RNAi screen identified 22 human dengue/West Nile virus (DENV/WNV) resistance genes that may be independent of known innate immune mechanisms. We hypothesized that of the 22 human genes identified, a subset would be functionally conserved in *Aedes aegypti* mosquitoes against flaviviruses. We identified 12 homologs of the 22 human genes in the *Ae. aegypti* genome. To evaluate their role in cellular resistance/antiviral defense against DENV, we used RNAi silencing in mosquitoes infected with DENV2. Among the 12 homologs, the silencing of two candidates, FKBP1 and the ATCAY, were associated with a significant increase in DENV titers as compared to the control groups. Depletion of the genes significantly increased dissemination of virus through the mosquito at 14 days post-infection. These data suggest that silencing of FKBP1 or ATCAY increased mosquito susceptibility to DENV replication and dissemination. Our results demonstrated that *Ae. aegypti* FKBP1 and ATCAY genes mediate resistance to DENV infections akin to what has been described for their orthologs in humans. In addition, we will discuss molecular profiling and characterization of the cellular and viral interacting partners of the two DENV-resistance genes.

A GLOBAL POPULATION GENOMIC SURVEY OF *AEDES AEGYPTI* VARIATION

Seth N. Redmond[1], Atashi Sharma[2], Igor Sharakhov[2], Zhijian Tu[2], Carolyn S. McBride[3], Jeffrey R. Powell[4], Bruce W. Birren[1], Maria Sharakhova[2], Daniel E. Neafsey[5]

[1]Broad Institute, Cambridge, MA, United States, [2]Virginia Tech, blacksburg, VA, United States, [3]Princeton University, Princeton, NJ, United States, [4]Yale University, New Haven, CT, United States, [5]Harvard School of Public Health, Boston, MA, United States

The *Aedes aegypti* aegypti (Aaa) mosquito is a highly competent vector of Zika, dengue virus, yellow fever and chikungunya; much of this competence derives from its preference for feeding on humans and ovipositing in urban habitats, and its global distribution. In contrast, the ancestral *Aedes aegypti* formosus (Aaf) subspecies is found only in sub-Saharan Africa, is less anthropophilic, and occurs in forested environs. Yet both subspecies can be found in sympatry in East Africa and are capable of producing fertile hybrids. With the improved reference genome of *Aedes aegypti* aegypti released earlier this year, we have conducted the first whole-genome resequencing-based global population study of this important vector. We have carried out deep Illumina sequencing of linked-read (10X Genomics) libraries for 24 individual mosquitoes in order to perform comprehensive variant discovery in both subspecies, including SNPs, insertions/deletions (INDELs), polymorphic mobile element insertions, and large structural variants such as inversions. We have characterized all of these polymorphism classes in multiple individuals from eight mosquito colonies founded from geographically disparate locations, including sympatric Aaa and Aaf populations (as defined by genetic clustering with African vs non-African populations). Examining signals of selection and diversity we find little evidence of restricted gene flow between sympatric Aaf and Aaa populations, but identify distinct founder effects for the non-African Aaa samples. Despite a reduction in diversity resulting from the expansion of Aaa to countries outside Africa, we also identify plentiful haplotypic and structural diversity in this mosquito which could facilitate its high phenotypic adaptability. We identify genes exhibiting evidence of positive selection in one or both subspecies. This work is a key step in the development of population genomic studies in this species of great public health importance; we hope that it will provide the foundation to subsequent studies of Aedes population structure and the potential for disease transmission by this vector.

1489

STARR-SEQ IN *ANOPHELES*: QUERYING NON-CODING DNA FOR FUNCTION

Michelle M. Riehle[1], Luisa Nardini[2], Inge Holm[2], Emmanuel Bischoff[2], Adrien Pain[2], Kenneth D. Vernick[2]

[1]Medical College of Wisconsin, Milwaukee, WI, United States, [2]Institut Pasteur, Paris, France

The vast majority of phenotypic variation in animals (>90% estimated from studies in Drosophila and human) is controlled by genetic variation in non-coding regulatory DNA, while genetic variation of protein-coding sequence contributes relatively little to phenotypic variation. Description of non-coding regulatory elements in mosquitoes, and their influence on mosquito biology and malaria transmission, remains little studied. Gene enhancers are an important class of non-coding regulatory elements. Enhancers influence gene transcriptional levels independent of position or orientation in the genome, even at a distance. Enhancers cannot yet be reliably identified by sequence signatures, but rather require functional assays for comprehensive detection. The availability of next-generation deep-sequencing has led to new strategies to screen non-coding DNA for functional enhancers. We have successfully modified and employed STARR-Seq (Self-Transcribed Active Regulatory Region Sequencing), a method first used on D. melanogaster, in *Anopheles coluzzii*, a prominent vector of malaria in West Africa. As proof of principle we have identified candidate enhancers near genes involved in insecticide resistance, innate immunity, and enhancers of developmental genes with good Drosophila orthologues. One of these Drosophila orthologues, an enhancer of Apterous, a gene important in wing development, was identified in *A. coluzzii* and functionally verified by luciferase assay. Results from other candidate enhancers will be discussed. Due to our unique experimental design we are not only able to query for enhancers in *A. coluzzii*, but have the power to examine how segregating genetic variation within species impacts enhancer activity and individual phenotype.

1490

THE HI-C APPROACH IMPROVED GENOME ASSEMBLIES AND REVEALED PRINCIPLES OF 3D GENOME ORGANIZATION IN MALARIA VECTORS

Igor V. Sharakhov[1], Varvara Lukyanchikova[1], Veniamin Fishman[2], Miroslav Nuriddinov[2], Nariman Battulin[2], Jiangtao Liang[1], Oleg L. Serov[2]

[1]Virginia Tech, Blacksburg, VA, United States, [2]Institute of Cytology and Genetics, Novosibirsk, Russian Federation

The spatial organization of the genome plays an important role in cell function. The main principles of the 3D chromosome folding in eukaryotes have been discovered using Hi-C - a groundbreaking technology that exploits *in vivo* chromatin proximity information. This method can also yield dramatically improved genome assemblies. The main goals of this study were 1) to apply the Hi-C approach to improving the fragmented genome assemblies for *Anopheles* species and 2) to understand the main principles of spatial genome organization in medically important malaria vectors. We performed a Hi-C protocol on 15-hour *Anopheles* eggs to generate 10 Hi-C libraries, including 2 biological replicas for 5 *Anopheles* species, which were sequenced with Illumina 150-bp paired-end sequencing. Using the combination of previous genome assemblies, physical chromosome mapping, and our Hi-C data, we have obtained a new accurate chromosome-level genome assembly for *Anopheles albimanus*, *Anopheles atroparvus*, *Anopheles coluzzii Mopti*, *Anopheles merus,* and *Anopheles stephensi*. We have detected scaffold orientation errors and misassemblies within the existing genome references and made the necessary corrections. The updated genome assemblies will improve

quality of genome annotation for the malaria vectors. We have identified species-specific patterns of short- and long-range chromatin interactions and inter-chromosomal contacts for all studied species. Our study revealed that: 1) anopheline genomes are structured into chromatin compartments, loops, and topologically associated domains (TADs) similarly to that in *Drosophila*; 2) the TAD/interTAD composition appears to be partially corresponding to the bands/interbands pattern of polytene chromosomes of malaria mosquitoes. In sum, our results have demonstrated the common fundamental principles of 3D genome organization in dipteran insects providing new facts for understanding of how architectural genome folding carries into effect within the nuclear space in malaria vectors.

1491

20-HYDROXYECDYSONE (20E) ACTIVATES MOSQUITO CELLULAR IMMUNITY AND LIMITS *PLASMODIUM* OOKINETE SURVIVAL

Rebekah Reynolds, Hyeog-Sun Kwon, Ryan Smith

Iowa State University, Ames, IA, United States

Mosquito blood feeding behavior is driven by the requirement of a nutrient-rich blood meal for egg development, which as a result, can potentially expose mosquitoes to blood-borne pathogens. Shortly after a blood meal, increased levels of the hormone 20-hydroxyecdysone (20E) stimulate yolk protein production in a process known as vitellogenesis through a heterodimeric receptor comprised of the ecdysone receptor (EcR) and ultraspiracle (USP). Reaching peak levels 24 hours after blood feeding, 20E expression levels coincide with the timing of malaria parasite invasion. While well-studied with respect to insect development, mating, and reproduction, little is known about the influence of 20E on mosquito immune response. Here we report the effects of 20E on the innate immune system of *Anopheles gambiae*, further defining the role of 20E in priming mosquito immunity for pathogen challenge. We demonstrate blood feeding can increase the phagocytic ability of mosquito hemocytes, an effect that can be reconsitituted through the injection of 20E alone. In addition, flow cytometry experiments demonstrate that 20E treatments promote shifts in hemocyte populations, suggesting 20E activates mosquito cellular immunity. When mosquitoes were primed with either the injection of 20E or the topical application of the 20E-mimicking insecticide, Halofenozide, malaria parasite numbers were significantly reduced. Upon further experiments, we confirm that 20E priming elicits immune responses limiting *Plasmodium* ookinete invasion. Preliminary experiments to understand the mechanisms of 20E immune priming by targeting the canonical EcR/USP heterodimeric receptor by silencing USP show no effect on parasite survival, suggesting an unknown receptor may mediate 20E-regulated immune responses. Together, these results suggest increased levels of 20E following blood feeding prime mosquito immunity to prevent development of pathogens present in the blood meal. With potential translational applications to reduce malaria transmission, these studies offer important insights into the contributions of mosquito hormones in shaping vector competence.

1492

DUAL ACTION LARVICIDAL-ADULTICIDAL SIRNA INSECTICIDES FOR BIORATIONAL MOSQUITO CONTROL

Keshava Mysore[1], Limb K. Hapairai[1], Longhua Sun[1], Jacob S. Realey[1], Azad Mohammed[2], David W. Severson[3], Molly Duman Scheel[1]

[1]Indiana University School of Medicine, Notre Dame, IN, United States, [2]The University of the West Indies, St. Augustine, Trinidad and Tobago, [3]The University of Notre Dame, Notre Dame, IN, United States

Although mosquito control is the primary means of combating vector-borne illnesses, the current pesticide repertoire is faced with great challenges to sustainability. Our recent screens in *Aedes aegypti* and *Anopheles gambiae* identified hundreds of small interfering RNA molecules (siRNAs) that function as mosquito larvicides. It was hypothesized that a subset of these siRNAs target genes required for viability at multiple stages of the mosquito life cycle and could therefore function as dual action pesticides with both larvicidal and adulticidal activity. To test this hypothesis, larvicidal siRNA molecules were screened for their ability to kill adult mosquitoes. The adult screens were conducted by delivering siRNAs to adult mosquitoes through both microinjection as well as through attractive sugar bait capillary feeding assays. ~20% of the larvicidal siRNAs screened to date, including several with target sites that are conserved in *Aedes, Anopheles,* and *Culex* mosquito species, were found to function as adulticides. Six of the most highly lethal siRNA molecules were down-selected for further characterization, including confirmation of the proposed modes of action for these pesticides in the *Aedes aegypti* nervous system. siRNA pesticide efficacy is being evaluated in simulated field and semi-field trials in which the most effective formulations are being assessed in container breeding sites, ovitraps, and attractive toxic sugar bait stations. It is anticipated that interfering RNA pesticides, which can be seamlessly integrated with existing control strategies, represent a new biorational means of controlling human disease vector mosquitoes.

1493

A WHOLE-GENOME TAXONOMIC SURVEY OF DIVERSE SOUTHEAST ASIAN MALARIA VECTORS

Brandyce St. Laurent[1], Christopher Clarkson[1], Nicholas Harding[2], Michael Fontaine[3], Jorge E. Amaya Romero[3], Robert Waterhouse[4], Sonia Goncalves[1], Mara Lawniczak[1], Dominic Kwiatkowski[1], Alistair Miles[2]

[1]Wellcome Sanger Institute, Hinxton, United Kingdom, [2]University of Oxford Big Data Institute, Oxford, United Kingdom, [3]Groningen Institute for Evolutionary Life Sciences, Groningen, Netherlands, [4]UNIL, Lausanne, Switzerland

With the emergence of drug-resistant parasites in Southeast Asia, understanding the role of diverse vector species and populations in the complex malaria transmission dynamics in this region is crucial to reduce and eliminate malaria. Genome sequencing could provide important insights, but as yet no population genomic studies have been performed on Southeast Asian anophelines. We describe results from a pilot study using Illumina deep whole-genome sequencing of 110 wild-caught individual Anopheles mosquitoes representing 27 different species, collected from Cambodia. We used these data to investigate major gaps in currently available reference data and analytical methods that need to be filled. In particular, we investigated the suitability of available reference genomes, finding that for only 14 out of the 27 species studied was there a reference genome that was sufficiently close and complete to enable standard methods for variant calling and population genomics to be applied. We also investigated the validity of current molecular techniques for identifying vector species. To provide an independent view of the taxonomic relationships between the individuals sequenced, we used three approaches: (1) de novo assembly of mitochondrial genomes; (2) alignment of reads to a small set of sequences that are highly conserved across all currently available reference genomes; and (3) a whole-genome reference-free analysis based on k-mer composition. Finally, we investigated the feasibility of studying genetic variation and recent selection in genes likely to be involved in insecticide resistance. These data will be publicly available as part of the MalariaGEN Vector Observatory, an open access resource of genome sequence data. Based on our experiences with these data, we discuss the next steps and technical foundations that require investment in order to unlock the full potential of genome sequencing as a tool for studying the geographical structure, ecology, and dynamics of the vector populations transmitting drug-resistant parasites in Southeast Asia, and for identifying genes conferring insecticide resistance and vector competence.

1494

REGIONAL FORUM ON *CANDIDA AURIS*: BUILDING PUBLIC HEALTH PARTNERSHIPS FOR THE PREVENTION, DETECTION AND RESPONSE OF EMERGING MULTIDRUG-RESISTANT FUNGAL INFECTIONS IN THE AMERICAS

Andres Espinosa-Bode[1], Diego H. Cáceres[2], Patricia Barrientos[3], Beatriz Lopez[1], Herberth Maldonado[4], Kristin Delea[5], Brendan Jackson[2], Benjamin Park[6], Tom Chiller[2], Alejandro Solis Martinez[3], Loren Cadena[1]

[1]Division of Global Health Protection, Central American Regional Office, US Centers for Disease Control and Prevention, Guatemala City, Guatemala, [2]Mycotic Diseases Branch, National Center for Emerging and Zoonotic Infectious Diseases, US Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Council of Ministers of Health of Central America and Dominican Republic Secretariat, San Salvador, El Salvador, [4]Center of Health Studies, Universidad del Valle de Guatemala, Guatemala City, Guatemala, [5]Division of Global Health Protection, US Centers for Disease Control and Prevention, Atlanta, GA, United States, [6]Division of Healthcare Quality Promotion, National Center for Emerging and Zoonotic Infectious Diseases, US Centers for Disease Control and Prevention, Atlanta, GA, United States

Candida auris and other emerging multidrug-resistant fungal infections (ERFs) have been recently identified as causes of serious healthcare-associated infections (HAI). In the Americas, four countries have reported *C. auris* HAI outbreaks since 2016. To address timely detection and control of *C. auris* and ERFs, the Council of Ministers of Health of Central America and Dominican Republic convened a regional forum for government public health leaders and subject matter experts in August 2017. CDC, in collaboration with PAHO, facilitated lectures and roundtable exercises to improve laboratory and surveillance capacity to detect *C. auris* and other ERFs and review antimicrobial resistance (AMR) policies. A fungal diagnostic capacity survey and an analysis of strengths, weaknesses, opportunities and threats were discussed to define short and mid-term action priorities. Colombia, Costa Rica, Dominican Republic, El Salvador, Guatemala, Honduras, Nicaragua, Panama, the United States and Venezuela were represented by 35 senior public health officials. Attendees included national directors of epidemiologic surveillance departments and public health laboratories (27%), AMR-HAI program coordinators (20%), healthcare epidemiologists and clinical infectious diseases specialists (31%), and laboratory specialists (22%). About 70% of laboratories and healthcare institutions from participating countries reported a low capacity to detect ERFs and report antifungal susceptibility patterns. Action priorities included integration of ERFs into national AMR surveillance systems, public health workforce training, strengthening fungal laboratory capacity and adoption of guidelines for diagnosis, management and surveillance. The *C. auris* regional forum provided an opportunity to increase antifungal resistance awareness and emphasized the need for closer collaborations to implement immediate public health actions. Further expansion of public health partnerships and a continued follow-up of identified action priorities are critical steps to the advancement of ERF surveillance and antifungal stewardship programs in the region.

1495

ADAPTING THE POPULAR OPINION LEADERS (POL) MODEL TO PROMOTE FAMILY PLANNING AND ZIKA PREVENTION BEHAVIORS AMONG ADOLESCENTS IN SANTA ANA, EL SALVADOR

Mathias Pollock[1], James Ayers[1], Jose Ivan Fuentes[2], Carmen Suarez[3], Amanda Kalamar[1], Ashley Sorgi[1]

[1]Population Services International, Washington, DC, United States, [2]Pan American Social Marketing Organization, San Salvador, El Salvador, [3]Population Services International, San Salvador, El Salvador

The arrival of the Zika virus and its established link to congenital malformations has produced a serious global health challenge. El Salvador has been among the countries most heavily impacted by Zika, forcing the government to officially recommend delaying pregnancy until 2018. In a country where one out of every three pregnancies occur in adolescents, there exists a clear need for outreach education and Social & Behavior Change Communication (SBCC) programming on family planning and Zika prevention. In 2017, PASMO El Salvador in collaboration with PSI designed a study to test the impact of an SBCC intervention using the Popular Opinion Leaders (POL) model on adolescent knowledge, attitudes, and practices regarding Zika prevention. POL is a community-based intervention designed to reduce risk behavior through the use of credible opinion leaders who diffuse information and model behavior to their social networks, it has been cited as a high impact intervention by the CDC. Formative research was completed to identify the target population, social networks, opinion leaders, and Zika baseline knowledge on prevention-related norms. A representative sample of student opinion leaders was identified based on social characteristics and a total of 272 students were trained on Zika prevention, family planning, risk reduction methods and effective and communication strategies to change peer norms. Baseline and first line end line surveys were completed by students within the target population to measure impact in 2017, with a further second end line surveys recently completed in January 2018. Preliminary analysis indicated some significant positive results. Regarding knowledge and attitudes about safe sex, 5/6 of indicators showed improvement. Additionally, 3/6 of Zika-specific knowledge indicators showed significant improvement. This study will help to validate that a peer-to-peer channel is a viable channel for increasing knowledge and Zika prevention behaviour amongst adolescents. This study will be used to advise the scale-up of Zika-education activities in other areas of El Salvador and the region.

1496

CHALLENGES OF ACHIEVING EFFECTIVE CONTRACEPTION WOMEN OF REPRODUCTIVE POTENTIAL IN MALARIA VACCINE TRIALS IN EQUATORIAL GUINEA

Basilio Micha[1], Esther Eburi[1], Ally Olotu[2], Antonio E. Sama[1], Stephen R. Manock[3], Carl D. Maas[4], Guillermo A. Garcia[5], Carlos Cortez[2], Salim Abdullah[6], Stephen L. Hoffman[3]

[1]MCDI, Malabo, Equatorial Guinea, [2]EGMVI, Malabo, Equatorial Guinea, [3]Sanaria, Maryland, MD, United States, [4]Marathon EG Production Ltd, Malabo, Equatorial Guinea, [5]MCDI, Silver Spring, MD, United States, [6]IHI, Bagamoyo, United Republic of Tanzania

Past studies have shown that the knowledge and use of contraception among women of reproductive potential in Equatorial Guinea is limited. Additionally, the national family planning program discourages the use of hormonal methods of birth control for females under the age of 18, and instead recommends the use of abstinence or barrier methods. Since a new law established in 2016 banned school attendance for pregnant students, pregnant teens have increasingly sought out induced abortions, which are illegal in the country. A recent clinical trial of PfSPZ Vaccine, which included females age 6 months to 65 years, revealed the difficulties of achieving effective contraception among volunteers who were inexperienced in the use of birth control. Of the 15 female volunteers of

childbearing age enrolled in the trial, 5 (33%) chose oral contraceptives, 5 (33%) chose a medroxyprogesterone injection, 3 (20%) chose abstinence + condoms, and 2 (13%) chose abstinence alone. Three pregnancies occurred among these volunteers during the trial. This experience highlighted the pressing need to expand sex education and contraceptive availability in the country, as well as provide more reliable forms of birth control such as medroxyprogesterone to all trial participants.

1497

DIAGNOSTIC LANDSCAPE FOR OUTBREAK DISEASES - AN OVERVIEW OF THE CHALLENGES

Laura T. Mazzola[1], Devy M. Emperador[1], Virginia Benassi[2], Marie-Pierre Preziosi[2], **Cassandra Kelly-Cirino**[1]

[1]Foundation for Innovative New Diagnostics, Geneva, Switzerland, [2]World Health Organization, Geneva, Switzerland

The 2014-2016 Ebola outbreak in West Africa and 2016-2017 Zika outbreak in the Americas led to an unprecedented response by the global community to rapidly develop new tools for prevention and control. However, challenges remain for developing tools to prepare for future epidemics and pandemics, hindered by limited surveillance data for outbreak-prone pathogens, lack of interest from in-vitro diagnostic companies to invest in products with episodic and small markets, limited resources in both clinical and reference laboratories, and difficulty in predicting the next epidemic or pandemic. To better prepare for future outbreaks, the WHO is leading the R&D Blueprint initiative, which works on the basis of identified priority diseases and collaborative R&D roadmaps, with the goal of accelerating the development and evaluation of medical countermeasures to enable effective and timely emergency response. To support the R&D roadmaps, we conducted diagnostic landscapes for 5 priority pathogens to understand the current technological gaps in affected low and middle income countries (LMICs). Cross-cutting gaps for all pathogens include: the lack of validated and regulated commercial assays that cover all relevant clades/lineages; the need for affordable point-of-care (POC) or near patient (NP) nucleic acid tests to rapidly diagnose and confirm infection; the need for more sensitive POC and NP antigen and antibody-specific immunoassays to support clinical and vaccine trials; the need for screening algorithms and multiplex syndromic panels to differentiate etiologies for acute febrile or respiratory illnesses; and the need for access to well characterized samples and external quality controls for test validation. Shifting from a reactive to proactive response must occur, as diagnostics are essential to building sustainable laboratory capacity that can be leveraged for an accelerated outbreak response, particularly in endemic settings. Understanding diagnostic gaps and en user needs will enable partners working in this area to prioritize product development that builds diagnostic capacity for both endemic and pandemic pathogens.

1498

MATHEMATICAL MODEL FOR QUANTIFYING THE IMPACT OF CONTROLLING DIABETES ON THE SPREAD OF TUBERCULOSIS

Emily E. Meyer, Latha Rajan, James M. Hyman

Tulane University, New Orleans, LA, United States

With the epidemiological transition, populations are now seeing remarkable increases in chronic diseases such as diabetes mellitus (DM). While it is known that tuberculosis (TB) progression is hastened and treatment outcomes worsened with the co-morbidity of DM, other interactions between the two remain to be elucidated. With the global push towards ending TB, it is necessary to broaden our scope of TB control by examining other areas that could be targeted. The goal of this project is to inform policy and programs in effective uses of resources, by focusing cost-effective interventions on targeted populations. Therefore, we have developed a mathematical model to determine the impact of adequate DM control on the progression and development of drug resistance. Our ordinary differential equation model population divides into risk groups based on severity of diabetes and level of diabetes treatment. By simulating the reduction of uncontrolled diabetes and performing sensitivity analysis of the model, we will quantify the impact of controlling diabetes on the spread and resistance of TB. Preliminary results are promising, but the very nature of this project precludes predictions at this point. Up to date results will be presented. By providing a model that can be adapted to individual populations or sub-populations, we hope to enable and enhance the global end-TB strategy.

1499

THE EFFECTIVENESS OF FILM-BASED EDUCATION AND OUTREACH FOR MONKEYPOX IN THE CONGO BASIN

Stephanie Tran[1], Clever Demokolo[2], Benjamin Monroe[3], Cuc Tran[3], Joelle Kabamba[4], Toutou Likafi[5], Robert Shongo Lushima[6], Saturnin Ibata[7], Mary G. Reynolds[3], Cynthia Moses[2], Andrea M. McCollum[3]

[1]Center of Disease Control and Oak Ridge Institute for Science and Education, Atlanta, GA, United States, [2]International Conservation and Education Fund, Kinshasa, Democratic Republic of the Congo, [3]Center of Disease Control, Atlanta, GA, United States, [4]Center of Disease Control, Kinshasa, Democratic Republic of the Congo, [5]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, [6]Ministry of Health, Kinshasa, Democratic Republic of the Congo, [7]International Conservation and Education Fund, Washington, DC, United States

Monkeypox (MPX) is a zoonotic disease endemic to Western and Central Africa. Handling and preparation of bush meat is a known risk factor for human disease; however, the reservoir species is unknown. In the Congo Basin, cases typically occur in remote areas with limited resources to health care. Films about MPX disease recognition, including an emphasis on healthcare and prevention, are shown as part of an outreach program in 49 villages within the Tshuapa Province, in the Democratic Republic of Congo (DRC) in 2011, 2013 and 2015. Educators evaluated the messages in the films by administering a survey to a proportion of participants before and after the films. In total, 1,353 participants completed the survey. 94.1% of respondents reported that they would seek hospital care for MPX after viewing the films, compared to the 77.8% before. There was also significant results of participants being able to identify more than one symptom of MPX, from 34.5% to 63.7% after viewing the film. Behaviors related to primate carcasses showed significance as well. A majority of respondents (90.4%) reported having eaten a primate before, with less than 2.6% of the participants stating they would continue to consume the primate. A similar film-based outreach program was also presented in the Republic of Congo (ROC), with comparable results for healthcare seeking behavior and the ability to better identify signs of disease in humans. However, in ROC, respondents did not report that they would change behaviors that involved consuming primates. Overall, the results suggest there is an improvement of disease knowledge and awareness of high-risk factors associated with MPX with the film based outreach model.

BUILDING BETTER GLOBAL HEALTH DELIVERY: THE EXECUTIVE NURSE LEADER

Viola Karanja[1], Graciela Cadet[2], Angeline Charles[2], Emmanuel Dushimimana[3], Shelia Davis[4], Marc Julmisse[2], Cory McMahon[4], Melissa Ojemeni[4]

[1]Partners in Health, Monrovia, Liberia, [2]Partners in Health, Mirebalais, Haiti, [3]Ministry of Health, Butaro, Rwanda, [4]Partners in Health, Boston, MA, United States

Nurses provide over 90% of primary care and constitute 30% of all health workers globally. They are natural change agents and the backbone of health care systems. As frontline health workers, nurses are often the first to identify emerging outbreaks. As demonstrated with the Zika virus in Haiti, nurses were at the forefront leading epidemiologic investigations,

developing protocols and establishing systems to optimize patient care. Although highly resourceful and systems-thinkers, nurses continue to be severely underrepresented at decision making tables. An inter-professional approach inclusive of nurses at decision-making tables is vital to strengthening health systems and combatting future emerging infectious disease and outbreaks. To begin to address this gap, Partners In Health (PIH) created the PIH Nightingale Fellowship, providing nurse leaders with the knowledge, tools, and confidence to lead at the highest level. The first cohort of Nightingale Fellows consists of four fellows from Haiti, Liberia, and Rwanda. The fellows participate in a one-year executive nurse leadership program. The fellowship includes two intensive in-person boot camps, online learning modules, mentorship from executive nurse leaders, and application of leadership concepts through leadership projects at their home institutions. The first cohort will complete their fellowship in June 2018. Preliminary results have demonstrated improvements in leadership practices, managing others, quality and safety, and strategic planning. All four fellows have become more engaged in the larger global nursing community including presenting at the Global Nursing Caucus, initiating academic partnerships, and actively participating in online global nursing forums. Three out of four fellows have been promoted to higher leadership positions. Fellows have self-reported increased confidence in their leadership abilities to represent nursing at all levels. Because of the preliminary success of this program, a new cohort of PIH Nightingale Fellows will begin in 2019 at the University of Health Equity in Rwanda-opened to nurses beyond PIH.

1501

THE GLOBAL BURDEN OF HELMINTH POLYPARASITISM: A SYSTEMATIC REVIEW AND META-ANALYSIS

Rose E. Donohue, Edwin Michael

University of Notre Dame, South Bend, IN, United States

Multiple human helminthiases are ubiquitous in the global South and epidemiological reports suggest polyparasitism is the norm rather than the exception. Impoverished communities exposed to multiple helminthiases are often also reported to be burdened with intestinal protozoan infections, malaria, tuberculosis, and human immunodeficiency virus (HIV). The objective of this study was to quantitatively evaluate the commonality of human helminth and helminth-protozoa polyparasitism; additionally, mixed infections of helminths with malaria, tuberculosis, and HIV were evaluated due to their extensive overlap in geographical endemicity with the global distribution of human helminthiases. In this ecological meta-analysis, we searched the PubMed and Web of Science databases for studies reporting the prevalence of single and multiple infections of helminth-only, helminth-protozoa, helminth-malaria, helminth-tuberculosis, and helminth-HIV. We used meta-analysis models based on resampling techniques to calculate the mean difference between the prevalence of polyparasitized and monoparasitized individuals. Polyparasitism was found to be significantly more prevalent than monoparasitism among helminth-only (difference 14% [95% CI: 5-23]) and helminth-protozoa infections (difference 15% [95% CI: 5-24]). Additionally, mixed infections of helminths with malaria, tuberculosis, and HIV were found to be common. These findings advance our understanding of the extent to which polyparasitism exists in the global South and the potential factors that could underlie this phenomenon. These findings support the call for more comprehensive disease control strategies that integrate treatment protocols or seek to redress the underlying determinants common across such infections.

1502

REACHING THE UNREACHABLE-LEVERAGING LESSONS LEARNED FROM MALARIA SERVICE DELIVERY PROGRAMS TO EXPAND INTEGRATED COMMUNITY CASE MANAGEMENT IN REMOTE AREAS OF PAPUA NEW GUINEA

Carrie M. Gheen, Shannon McVey

Population Services International, Port Moresby, Papua New Guinea

Access to care remains a challenge for those living in Papua New Guinea (PNG), many of the aidposts are not functional and quality services for malaria, pneumonia and diarrhoea are not always available. The Home-based Management of Malaria (HMM) program managed by Population Services International (PSI) attempted to bridge the malaria service gap in three provinces (East Sepik, East New Britain and Sandaun) using volunteer community-based distributors (CBD). Provinces were selected based on malaria incidence, access to health services and buy-in from the Provincial Health Administration (PHA). The HMM program covered an estimated population of 616,559 with 1,000 active CBDs. In 2016, PSI conducted an evaluation using a household survey, the first of its kind PNG, to compare treatment seeking behaviour for fever among caregivers for children under 5 in HMM and non-HMM communities. To explore potential for integrated community case management (iCCM), the study assessed knowledge, attitudes and treatment seeking practices for diarrhoea and pneumonia. PSI also conducted 13 qualitative interviews with CBDs to understand their experience during the HMM project. Survey results indicated a positive impact of HMM in most rural provinces. In Sandaun, availability of CBDs correlated with fewer caregivers first treating at home and CBDs were their first choice of external care. In East Sepik and Sandaun, CBDs were the preferred source of care by caregivers because they were 'close by or easy to reach'. Results in East New Britain were different, due to increased use of hospitals and less use of CBDs. The results found a high prevalence of diarrhoea, but only 7% of caregivers knew correct treatment. Pneumonia was less reported and understood- 50% of caregivers could not name the main symptoms. Interviews with CBDs indicated a positive perception of HMM and their desire to continue serving. Given the success of HMM in rural areas, we should consider using this channel to roll out iCCM. Discussion on how to ensure continued quality should be considered as well as the operating model with the PHA to deepen integration into the public-sector service provision.

1503

ROLE OF HEALTH-SEEKING BEHAVIOR AND NON-ADHERENCE IN ELIMINATION AND ON DISEASE DYNAMICS OF VISCERAL LEISHMANIASIS IN BIHAR, INDIA

Mugdha Thakur, Anuj Mubayi

Arizona State University, Tempe, AZ, United States

Visceral Leishmaniasis (VL) is one of the neglected vector-borne tropical diseases with an estimated 40,000 cases and 20,000 deaths annually worldwide. Of these almost 45% cases are from India in which more than 90% are from the Bihar state. In 2005, the governments of India, Nepal and Bangladesh in collaboration with the World Health Organization (WHO) launched a regional initiative to eliminate VL. Elimination is defined as reducing incidence to less than one per 10,000 inhabitants per year at sub-district level so that it would cease to be of public health importance. Elimination was not achieved in spite of multiple target efforts and years (2015 and 2017 successively); WHO has now set the target to year 2020. The national strategy for elimination, which is in line with the regional strategic framework for Southeast Asia, includes early case detection, integrated vector management, surveillance, strengthening human resource capacity, control program management etc. However, these efforts fail to monitor hidden population of patients initiating treatment but not following it properly. Thus, the current challenges in controlling VL in Bihar include (may not be limited to) delay in seeking healthcare, treatment non-adherence, immunodeficiency due to protein malnutrition,

supply and availability of drugs and poor surveillance. This study highlights the critical mechanisms like health-seeking behavior of infected individuals, their treatment non-adherence and the role of self healing individuals as potential for disease elimination via data-driven dynamic mathematical models. These mechanisms are crucial because they act as hindrance in the elimination process delaying the achievement of the target. This work also assesses the combined effects of improving efforts in this direction along with enhanced integrated vector management programs. We conclude that, although it is important to put efforts in decreasing delay in health-seeking and increasing perfectly adherent cases, the highest impact would be caused by completely treating temporarily recovered non-adherent individuals who act as the hidden reservoirs for infection.

CONNECTING GLOBAL AND LOCAL PUBLIC HEALTH: WHY GLOBAL HEALTH SECURITY MATTERS TO LOCAL JURISDICTIONS IN THE U.S.

Zara Ahmed, Megan Ramsden, Rebecca Bunnell

US Centers for Disease Control and Prevention, Atlanta, GA, United States

Global health security (GHS) requires public health capacity to identify health threats, stop outbreaks, and save lives. In addition to health, there are many other ways in which GHS benefits the US. To assess global and local interconnectivity, we examined ways GHS relates to health and economic threats at the state and local level throughout the U.S. We assessed potential connections of GHS to domestic concerns, namely: state and local preparedness, travel, tourism, education, exports, jobs, agriculture, and partnerships. Publicly available data were gathered from seven US Government Departments (Agriculture, Commerce, Defense, Health and Human Services, Homeland Security, State, and Transportation) and from all 50 state government websites. A total of 22 data points were abstracted from these sources. Case examples of human imported diseases, zoonotic disease outbreaks, global health partnerships, and economic impact of outbreaks were drawn from news media and US government reports. The nature of interconnectivity varied by state, highlighting the importance of different facets of GHS across the country. For example, Texas has been the lead state exporter since 2010, with $264.1 billion in goods exported overseas in 2017 and over 900,000 export-supported jobs. Comparatively, poultry is the top sector of Georgia's top industry (agriculture), with 1.4 billion broiler chickens produced in 2016, making avian influenza a major concern. For smaller states, data helped underscore that GHS's relevance is not limited to states with a high volume of travelers; statistics about state residents overseas and companies with global ties further made this connection. Challenges in assessing interconnectivity using public domain data include the need for rigorous validation of data and reputable sourcing. However, data aids in making clearer the benefits of stopping outbreaks overseas and shows linkages to states. Although there are differences across states, using local data may illuminate the links between domestic issues and GHS. The number and variety of connections between GHS and states may make GHS more relevant to US stakeholders.

1505

PREGNANT WOMEN AND VACCINES AGAINST EMERGING PATHOGENS: ETHICS GUIDANCE ON AN INCLUSIVE AND RESPONSIVE RESEARCH AGENDA AND EPIDEMIC RESPONSE

Carleigh Krubiner[1], Ruth Faden[1], Ruth Karron[2], Margaret Little[3], Anne Drapkin Lyerly[4], The PREVENT Working Group[5]

[1]Johns Hopkins Berman Institute of Bioethics, Baltimore, MD, United States, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [3]Georgetown University Kennedy Institute of Ethics, Washington, DC, United States, [4]Center for Bioethics at University of North Carolina, Chapel Hill, NC, United States, [5]Various institutions

Zika virus, H1N1, and Ebola have called attention to how infectious disease outbreaks can severely - and at times uniquely - affect the health interests of pregnant women and their offspring. These examples highlight the critical need to proactively consider pregnant women and their offspring in vaccine research & development (R&D) to combat emerging infectious diseases. New vaccines are rarely designed with the specific needs of pregnant women in mind, and evidence about their safety and efficacy in pregnancy is often limited and late in coming. Significant questions remain about what is required to ensure that pregnant women and their offspring are adequately protected and fairly accounted for in vaccine development and deployment for emerging epidemic threats. To develop guidance, we convened an expert working group comprised of ethicists, public health practitioners, vaccine researchers, and maternal and child health specialists. We also conducted consultations with more than 70 leading experts in vaccine science, maternal-fetal medicine, public health preparedness and response, regulatory affairs, and ethics oversight. Literature reviews supplemented findings from consultations and working group meetings. The guidance highlights a vision in which: pregnant women and their offspring have safe, effective, and accessible vaccines to protect them against emerging epidemic threats; pregnant women and their offspring can benefit from advances in vaccine technologies and are note left behind as new products are developed; and pregnant women are not unjustifiably denied opportunities to participate in vaccine trials from which they may benefit solely because they are pregnant. A set of strategic objectives and concrete recommendations are put forth, focusing on: (I) Public Health & Science Preparedness, (II) Vaccine R&D, (III) Vaccine Deployment During Outbreaks. Adequately addressing the interests of pregnant women in the development and deployment of vaccines against emerging pathogens is essential to mitigating the potential harms they and their offspring face in epidemics. It is also a matter of justice and respect.

1506

INTERNATIONAL BIOLOGICAL REFERENCE PREPARATIONS FOR EMERGING INFECTIOUS DISEASES: VITAL TOOLS IN EPIDEMIC PREPAREDNESS

Tommy Rampling[1], Mark Page[2], Peter Horby[3]

[1]University College London, London, United Kingdom, [2]National Institute of Biological Standards and Control, Potters Bar, United Kingdom, [3]University of Oxford, Oxford, United Kingdom

Recent years have seen unprecedented investment in research and development (R&D) for countermeasures for high threat pathogens, with specific and ambitious objectives for development of diagnostics, therapeutics, and vaccines. Biological reference materials (BRMs) are materials, such as antigens, antibodies and nucleic acids, with carefully standardised biological activity. The inadequate availability of BRMs for high-threat diseases with epidemic potential poses a genuine obstacle in pursuit of R&D objectives, and the lack of a comprehensive and equitable framework for developing BRMs is a weakness. BRMs are essential for calibration of bioassays and standardisation of vaccines and bio-therapeutics, allowing for data comparison and harmonisation. In 2016, the WHO launched the R&D Blueprint, an initiative that seeks to enhance global health security by building upon the successes, and addressing the gaps identified during the 2014 Ebolavirus disease (EVD) epidemic. Central to the blueprint is a list of priority diseases and a roadmap for each disease that encompasses diagnostics, vaccines and therapeutics. During the 2014 EVD outbreak the lack of Ebola RNA, antigen and antibody BRMs hampered the development of accurate diagnostics and vaccines. This is echoed in the recent MERS-CoV and Zika virus epidemics. Interim antibody reference standards for Ebola were approved in 2015, otherwise no international serology BRMs exist for any other disease on the R&D Blueprint. Availability of BRMs for these diseases prior to occurrence of outbreaks would facilitate product development and research activities. In this presentation we outline the need for internationally standardized BRMs for high threat pathogens, as a core element of global health security. We outline key components of a structured framework to address this deficiency, with the aim of standardising approaches to sourcing and acquiring material for BRM development for priority high-threat pathogens

to allow for production of BRMs in advance of outbreaks, or the early initiation of sample acquisition and BRM development, in the event that an outbreak occurs.

1507

IMPROVING PRECISION OF HEALTH CAMPAIGNS THROUGH AN API FOR IDENTIFYING RESIDENTIAL BUILDINGS

Kehsin Su[1], **Ricardo Andrade-Pacheco**[2], Evelyn Li[1], Legeng Liu[1], Max Feng[1], Hugh J. Sturrock[2]

[1]University of California Berkeley, Berkeley, CA, United States, [2]University of California San Francisco, San Francisco, CA, United States

Health programs focused on delivering services at the household level, such as vaccination or indoor residual spraying of insecticide campaigns, can benefit from accurate maps of residential buildings. Most open building footprint data lack information as to whether buildings are residential or not. While previous work has demonstrated how building data from OpenStreetMaps (OSM) can be classified as residential and non-residential by means of machine learning techniques, many field workers do not have the capacity to implement these algorithms. Here we present the development of an Application Programming Interface (API) where we make these models available to users online. By defining a polygon of interest, the user can receive a geojson file of all OSM buildings with their predicted residential/non-residential classification. The results of the query can be downloaded and integrated into the health program workflow if needed.

1508

MULTI-LEVEL CORRELATES INFLUENCING PROVIDER DEVIATIONS FROM ESTABLISHED PEDIATRIC TREATMENT GUIDELINES: A SYSTEMATIC REVIEW AND META-ANALYSIS

Chantal L. Donahue[1], Dorothy L. Mangale[2], Kirk D. Tickell[2], Donna M. Denno[2], Judd L. Walson[2], Arianna R. Means[2]

[1]University of Washington, Seattle, WA, United States, [2]University of Washington, Childhood Acute Illness and Nutrition Network, Seattle, WA, United States

Household surveys from 39 countries indicate that many acutely ill children are not provided necessary evidence-based interventions upon presentation at health facilities; half of children with suspected pneumonia receive antibiotics, one-third of children with diarrhea receive ORS, and <1% of children with diarrhea receive zinc. Additionally, evidence from multiple settings indicates that training alone does not improve adherence to guidelines. The purpose of this systematic review is to identify the multi-level correlates that influence provider deviations from established pediatric treatment guidelines. This systematic review followed PRISMA guidelines and included studies indexed on Medline and Embase. Eligible studies included pediatric populations (ages 10 and under) and were conducted in low-and-middle-income settings. Studies included randomized designs, quasi-experimental designs, and observational studies. Of the 2,896 titles retrieved, 339 studies were identified for full-text review, and 41 full-text articles met inclusion criteria. 16 full-text articles remain under review, pending disaggregated data contributions from study authors. It is estimated that all data will be made available by May 2018 and meta-analyses will be completed in July 2018. Included studies identified patient-, provider-, facility-, intervention-, and guideline-level correlates of guideline adherence and deviation. Thus far, 18 distinct correlates have been identified, with provider training, perceived disease severity, and patient age emerging as the most commonly studied. We will conduct meta-analyses to derive pooled estimates of the relative influence of each correlate on guideline adherence or deviation. Interim results indicate that there is extensive research on factors associated with training and provider experience and that there is less research on multi-level factors influencing practice behaviors, above and beyond the providers themselves. Identification and appreciation of multi-level factors will be important for identifying health systems solutions for the complex drivers of guideline deviation.

1509

USING PARTICIPATORY WORKSHOPS TO ASSESS COMMUNITY ALIGNMENT OR TENSION FOR CHILD MORTALITY SURVEILLANCE INVOLVING MINIMALLY INVASIVE TISSUE SAMPLING

Ahoua Kone[1], Emily Lemon[1], John Blevins[1], Saquina Cossa[2], Faruqe Hussain[3], Kennedy Ochola[4], Yosef Zegeye[5], Zerihun Girma[5], Nonhlanhla Ngwenya[6], Maria Maixenchs[7], Elizabeth O'Mara[8]

[1]Rollins School of Public Health, Emory University, Atlanta, GA, United States, [2]Centro de investigacao de Saude de Manhica, Manhica, Mozambique, [3]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [4]Kenya Medical Research Institute, Kisumu, Kenya, [5]Haramaya University, Harar, Ethiopia, [6]Medical Research Council: Respiratory and Meningeal Pathogens Research Unit, University of the Witwatersrand, Johannesburg, South Africa, [7]Barcelona Institute for Global Health, Barcelona, Spain, [8]Centers for Disease Control and Prevention, Atlanta, GA, United States

The Child Health and Mortality Prevention Surveillance (CHAMPS) Network aims to address gaps in knowledge about under-5 mortality by determining the causes of death in seven countries through multiple methods of data collection, including minimally invasive tissue sampling (MITS). Adapting earlier methods of community health asset mapping, we developed a novel community entry activity designed to introduce child mortality and pregnancy surveillance activities. Workshops for community members and community leaders were conducted to elicit perspectives related to child death and dying; autopsy; medical/clinical care and antenatal care; and alignments/tensions between CHAMPS and community priorities. In total, 72 workshops were conducted with 1,579 participants in five CHAMPS sites - Bangladesh, Ethiopia, Kenya, Mozambique, and South Africa - between October 2016 and March 2018. In the aggregate, 80% of participants' responses reflected alignment between mortality surveillance (including MITS) and community norms. However, there was tension in the context of certain cultural factors, most notably religious beliefs. 57% of participants agreed that any procedure (including MITS) conflicting with the burial practices of a religious tradition should not be conducted and 48% agreed that care of the body after death was a religious/spiritual issue and the work of God. The majority of those who held such beliefs did not indicate that they would have negative perceptions of others who consented to MITS. However, for a significant minority, such beliefs could support stigmatizing attitudes toward anyone who participated: 21% of all participants said that no parents should consent to MITS and 10% stated a general belief that tissue removal was always wrong. The results underscore the importance of engaging communities to understand cultural and religious beliefs that may influence the feasibility, including acceptability and gain appreciation for CHAMPS post mortem procedures.

FOCUSING BEHAVIOR CHANGE EFFORTS TO MAXIMIZE USAID-LED ZIKA PREVENTION EFFORTS IN CENTRAL AMERICA AND THE CARIBBEAN: LESSONS FOR FUTURE PUBLIC HEALTH EMERGENCIES

Jessie Pinchoff[1], Alice Payne Merritt[2], Arianna Serino[3], Martha Silva[4], Priya Parikh[2], Gabrielle Hunter[2], Paul Hewett[5]

[1]Population Council, New York, NY, United States, [2]Johns Hopkins Center for Communication Programs, Baltimore, MD, United States, [3]U.S. Agency for International Development, Washington, DC, United States,

[4]Tulane University, New Orleans, LA, United States, [5]Population Council, Washington, DC, United States

Since the Zika outbreak in 2015, there has been a proliferation of behavior change messages and campaigns, with over 30 specific preventive behaviors being promoted one year after the initiation of USAID's response. This large number of behaviors presents a challenge to the potential effectiveness of social and behavior change (SBC) programming efforts to prevent Zika at the household and community level. Clear, specific, and concise messages that can be repeated multiple times are necessary to effectively promote behavior change. This situation prompted USAID and partners to develop an evidence-based strategy to select focus behaviors and harmonize messaging across the USAID response. The process began with a literature review of all behaviors being recommended, with five excluded due to lack of strong evidence for efficacy. Two behaviors were also excluded from the prioritization process because USAID was not procuring the required materials. Lastly, the focus was on individual or household level behaviors, those whose locus of control remained within individuals in the household. The literature review included all peer-reviewed journal articles published between 2010 and 2018, including any reports or seminal publications prior to 2010, regarding any *Aedes aegypti* spread diseases. Grey literature or unpublished data provided by implementing partner organizations was also collected through the Zika Communication Network. The findings were compiled into an evidence matrix combining evidence on efficacy and effectiveness of behaviors. Subsequently, four criteria were developed to aid in the prioritization: 1) efficacy of the behavior to prevent negative pregnancy outcomes; 2) potential to reduce Zika transmission at population level; 3) Frequency required to be effective; 4) Ease of access to materials required. Criteria were ranked high, medium or low for each behavior through a combination of evidence review, and discussions with key informants and implementing partners. The goal is to harmonize Zika response efforts around a shorter and more specific set of key prevention behaviors to reduce the risk of Zika transmission.

1511

THE USE OF A CAMPAIGN INFORMATION MANAGEMENT SYSTEM FOR RAPID AND EFFICIENT MASS DISTRIBUTION AND MONITORING OF LONG-LASTING INSECTICIDAL NETS IN AN URBAN SETTING OF BIOKO ISLAND

Jose Osa Osa Nfumu[1], Godwin Fuseini[1], Jordan Smith[1], Jeremias Nzamio[1], Brent Atkinson[1], Carlos Cortes Falla[1], Wonder Philip Phiri[1], Christopher Schwabe[2], Guillermo Garcia[2]

[1]*Medical Care Development International, Malabo, Equatorial Guinea,* [2]*Medical Care Development International, Silver Spring, MD, United States*

It is well established that long-lasting insecticidal nets (LLINs) can be used as a core vector control tool to reduce malaria transmission in endemic countries. LLINs provide both personal and community protection against malaria. For LLINs to provide community protection, universal coverage of every household having at least one LLIN for every two people in a given population is recommended. Ensuring universal coverage during mass distribution campaigns, and monitoring the use and durability of nets in urban settings characterized by high population density and mobility, particularly where houses are not enumerated, poses a major challenge. The Bioko Island Malaria Control Project (BIMCP) developed an Open Data Kit (ODK) and Geographical Information System (GIS) based Campaign Information Management System (CIMS) in 2014 for efficient and rapid household enumeration, LLIN distribution, and campaign monitoring on Bioko Island. The CIMS continues to be used in 2018 to carry out a mass LLIN distribution campaign on Bioko Island. Approximately 175,000 LLINs will be distributed door-to-door to a population of about 330,000 people in 85,000 households during a five-month period by a team of 50 enumerators and 100 volunteers. This system helps to identify enumerated households for field teams, facilitates revisiting closed or rejecting households to increase coverage, and can track nets distributed at the household level. Household information can be captured and analyzed in near-real-time to estimate coverages within defined geographic areas and used to allocate and mobilize additional resources if desired coverages have not been reached. The use of the CIMS tablet application has required substantial training for enumerators, but has ultimately increased operational efficiency and programmatic integrity, and has been adapted for use in multiple concurrent large-scale campaigns.

1512

FINE-SCALE MAPPING OF LOCALITIES HOUSEHOLDS TO PLAN, IMPLEMENT, MONITOR AND EVALUATE MALARIA CONTROL CAMPAIGNS ON BIOKO ISLAND, EQUATORIAL GUINEA

Jeremias Nzamio[1], Jordan Smith[1], Jose Osa Osa Nfumu[1], Wonder Philip Phiri[1], Carlos Cortes Falla[1], Megan Perry[2], Christopher Schwabe[2], Guillermo Garcia[2]

[1]*Medical Care Development International, Malabo, Equatorial Guinea,* [2]*Medical Care Development International, Silver Spring, MD, United States*

The Bioko Island Malaria Control Project (BIMCP), in collaboration with the National Malaria Control Program (NMCP) of the Ministry of Health and Social Welfare (MOHSW) of Equatorial Guinea, has been implementing malaria control activities on Bioko Island for at least 14 years. Like many developing nations, the urban environment of Bioko Island is characterized by informal housing, a lack of a household address system, and the absence of formalized geospatial administrative units. In 2011, the BIMCP established a Geographic Information System (GIS) to enumerate households to track household interventions and has collaborated with the Ministry of the Interior to delineate geopolitical administrative units. The GIS mapping efforts have allowed the BIMCP and the Equatorial Guinea Malaria Vaccine Initiative (EGMVI) to plan, mobilize, monitor, evaluate interventions at the household level, and aggregate results at different spatial scales depending on their needs. The system has been possible largely due to considerable support from project donors, collaboration with the government of Equatorial Guinea, and also due to the size of the island (2,017 km2), with less than 100 km2 of which is populated. These factors have made it possible to map populated areas at very fine-scales within small geopolitical units undergoing rapid change due to the country's economic development. Fine-scale urban mapping has been a challenge on Bioko, as 95% of the inhabitants live in a densely populated urban core representing more than half of the island's total populated area. High-resolution mapping of localities and households has enabled the BIMCP to track household interventions in near-real-time, and the outputs have empowered local authorities and leaders to take action in their communities to increase intervention coverage and individual uptake.

1513

ASSESSING IRS PERFORMANCE AND BARRIERS IN A GENDER-INTEGRATED VECTOR CONTROL PROGRAM ON BIOKO ISLAND, EQUATORIAL GUINEA

Jamie Mullaney[1], Megan Perry[1], Liberato Motobe[2], Lucas Ondo Nze[2], Matilde Riloha Rivas[3], Wonder Philip Phiri[2], Carlos Cortes Falla[2], Guillermo Garcia[1]

[1]*Medical Care Development International, Silver Spring, MD, United States,* [2]*Medical Care Development International, Malabo, Equatorial Guinea,* [3]*Ministry of Health and Social Welfare, Malabo, Equatorial Guinea*

Due to social, economic and physiological barriers, women have historically been underrepresented in spray programs across Sub-Saharan Africa. The Bioko Island Malaria Control Project (BIMCP) has implemented IRS as one of the primary vector control strategies for malaria control on Bioko Island since 2004. This study aims to assess the performance and barriers for engaging women to become IRS operators and assume supervisory positions using data from 2012 to 2018, where approximately 35% of all spray operators have been female. In part, this gender balance has been achieved through guidelines such as equal pay for men and women,

ensuring physical work environment provides safe and private areas for women, pregnancy testing for female operators before every round for safety reasons, and continued financial support for women during maternity leave. The BIMCP collects routine IRS data for every sprayer, assesses the quality of spraying techniques and guidelines through direct observation, and quantifies the insecticide sprayed on walls with high-performance liquid chromatography (HPLC) for assessing sprayer quality control. This study will evaluate the gender policies in place to assess the engagement of women in vector control. It will evaluate not only the productivity of male and female counterparts, comparing attendance and the average number of households and rooms sprayed daily; it will also evaluate the quality of insecticide coverage achieved by male and female operators using results from the HPLC studies and the number of performance infractions recorded by supervisors. As it enters Phase IV of implementation, the BIMCP hopes to continue to engage female spray operators and encourage them to seek higher positions as supervisors and team managers.

1514

IMPACT OF POPULATION MODELING CHOICES ON EPIDEMIOLOGICAL ESTIMATES: IMPLICATIONS FOR INTEGRATED DISEASE CONTROL

Corinna Y. Keeler, Varun Goel, Michael Emch

University of North Carolina - Chapel Hill, Chapel Hill, NC, United States

Epidemiological analyses rely on accurate population counts. Increasingly, in locations with scarce or infrequent census data, modeled population estimates based on satellite data or demographic surveys are used as the denominator for infectious disease prevalence estimations and intervention targeting, in place of empirically determined population counts. While these modeled population datasets serve a useful function, there have been few studies evaluating how the selection of population data impacts the resultant disease prevalence estimates or other relevant public health measurements. This project uses malaria control in the Democratic Republic of Congo (DRC) as a case study to examine how the choice of population dataset impacts how underlying spatial distributions of human populations are understood, and therefore how the selection of population data effects the calculated estimates of malaria prevalence and unmet bednet need. The DRC is a particularly salient study site for this work since there has not been a comprehensive national census since 1984, and health studies in the country frequently draw on modeled population estimates. Using spatial methods, this study compares three widely available modeled population datasets to identify the health zones and provinces in the DRC displaying significantly high variability in population size across different population data sources. Of the 515 health zones in the DRC, 263 exhibit a difference in modeled population size of 50,000 or more between the LandScan and WorldPop population datasets. Health zones with the highest variability between population datasets are examined to identify environmental, demographic, and infrastructure characteristics that correlate with low consistency in population estimation. The variability in population estimates in each health zone is applied to understanding variation in the burden of malaria among key population groups in the DRC and targeting bednet distribution campaigns. Implications for selecting sites for future microcensuses to guide malaria interventions are discussed.

1515

UPTAKE OF CONTRACEPTIVES AFTER ABORTION AMONG ADOLESCENT GIRLS AT QUEEN ELIZABETH CENTRAL HOSPITAL IN BLANTYRE, MALAWI

Thokozani Ireen Mtonda, Mercy Pindani, **Elizabeth Glaser**

Kamuzu College of Nursing-University of Malawi, Blantyre, Malawi

In Malawi, contraceptive use among adolescents is low, resulting in early childbearing with increased risk of obstetric complications and maternal death. However, there are opportunities to provide contraceptive counseling even after an initial pregnancy has occurred. This study, therefore, explored factors influencing uptake of contraceptives among adolescent girls receiving post abortion care at a large urban facility, Queen Elizabeth Central Hospital, in Blantyre, Malawi. We employed a descriptive cross-sectional quantitative study, randomly sampling 97 adolescent girls meeting the inclusion criteria. Participants were interviewed using a structured questionnaire. Data were entered on EPIDATA and analyzed via SPSS version 20.0. We analyzed socio-demographic statistics, chi-square, and fisher's exact tests to explore associations between socio-demographic characteristics and uptake of contraceptives. Over half 58 (59.8%) of 97 adolescent girls who came for PAC services accepted a contraceptive method. Fifty-six (96.6%) of those that chose to use contraceptives were between 16 and 19 years old with the most common method of choice being the oral contraceptive pill. The main source of information on contraceptive use and sexuality were peers, and the most common reason for refusing contraceptives was fear of side effects. Privacy and confidentiality were the main facilitating factors in accepting contraceptives while parental disapproval was found to be the main hindering factor. Contraceptive uptake was significantly associated with education (fisher's exact p=0.022), religion (fisher's exact p=0.034), and significantly associated with age (fisher's exact p=0.044). Based on the results, we encourage strengthening youth-friendly services at PAC sites, family planning outreach to very young teens, programs that focus on retaining young women in school, and collaboration with local youth agencies to potentially avert unwanted pregnancies and unsafe abortions in teens.

1516

HOUSEHOLD HEALTH EXPENDITURES FOR BIRTH IN BLANTYRE, MALAWI

Annielisa Kambale, Gibson Masache, **Elizabeth Glaser**

Kamuzu College of Nursing-University of Malawi, Blantyre, Malawi

Health financing is one of the seven priority areas identified in the Malawi National Health Policy, noting that the nation struggles with inconsistent domestic funding, and inefficient and inequitably allocated resources. These larger issues filter down to impact households in paying for normal life events. In this study we examined health expenditures for births in Malawi, recruiting 388 participants using purposive sampling, collecting data via structured questionnaires on expenditures incurred while planning for an impending birth. We then asked participants to make discrete choices on funding future births. Data analysis was conducted using SPSS version 20.0. Statistics were presented using frequencies and percentages. The results indicate that 97% of the sample paid for birth services of which 33% of participants had been asked to pay informal fees while accessing birth services at public health facilities, the site of most births (87%). Fees were requested for services or commodities such as medicines, ultrasound services, and pregnancy tests. More than 58% of the costs were paid out of pocket as only 10% of participants had Health Insurance as a mode of prepayment. Other expenses such as transport, medicines from private pharmacies, food, and materials that hospitals require laboring women to provide (tarp, sheets, etc) contribute additional oop costs. Participants rely on public health facilities for birth because they offer "free "services. Yet, in most cases the cumulative payments associated with birth and the perinatal period can exceed 10% of income in period, constituting a catastrophic cost. When offered the choice, 57% of participants expressed willingness to enroll in a health scheme. When offered five choices for financing, 32.8% of participants chose bank savings, 32.3% health insurance , 21.7 community based, 7.6% group financing, and 5.6% chose to pay solely out of pocket. Malawians in an urban setting expressed interest in alternate means of paying for birth. The government of Malawi could improve access to maternal health services via financial risk protections rather than relying solely on out of pocket financing.

1517

BROAD CONSENT FOR DATA SHARING

Phaik Yeong Cheah[1], Nattapat Jatupornpimol[1], Borimas Hanboonkunupakarn[2], Napat Khirikoekkong[1], Nicholas P. Day[1], Michael Parker[3], Susan Bull[3]

[1]Mahidol Oxford Tropical Medicine Research Unit, University of Oxford, Bangkok, Thailand, [2]Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [3]The Ethox Centre, University of Oxford, Oxford, United Kingdom

There is now increasing expectation from research funders, regulatory agencies, and journals for greater sharing of individual-level data from health research. Broad consent appears to be the preferred mechanism to obtain consent for such sharing. There is a paucity of empirical data on broad consent especially in tropical medicine research. The present study seeks to understand what aspects of data sharing are considered most important to inform participants about in the context of broad consent, and the best ways to explain complex and abstract topics relating to data sharing. This was a qualitative study conducted in Bangkok and at the Thai-Myanmar border town of Mae Sot. We conducted 18 semi-structured interviews and four focus group discussions with a total of 37 participants from three stakeholder groups. Our study identified the type of information that participants thought was important to provide: that data sharing has potential benefits, the data will be de-identified, that mechanisms are in place to minimize potential harms to participants, and participants will not be inconvenienced by such sharing. There was however, no consensus among participants on how much information about data sharing to provide. Our data suggest that how much information should be dependent on the primary study, the study population, the individual research participant and the context. During the qualitative study, we found that communicating data sharing to participants was challenging. Additionally, participants thought that, in most cases, research participants should be able to take part in the primary biomedical study without consenting to data sharing. Communicating the concept of data sharing to participants was found to be challenging, with the level of understanding of data sharing and views on how best to consent to data sharing varying with context and participant population.

1518

GEOGRAPHICAL ASSESSMENT OF SIX MOST COMMON INFECTIOUS DISEASES IN SEVEN LARGE CITIES IN INDONESIA USING GEOGRAPHICAL INFORMATION SYSTEMS

Antonius Arditya Pradana[1], Akbar Fahmi[2], Nurhayati Nurhayati[1], Mochamad Helmi Aziz[1], Herman Kosasih[1], Muhammad Karyana[3]

[1]Indonesia Research Partnership on Infectious Disease (INA-RESPOND), Jakarta, Indonesia, [2]Airlangga University/Dr. Soetomo Hospital, Surabaya, Indonesia, [3]National Institute of Health Research and Development (NIHRD), Ministry of Health Republic of Indonesia, Jakarta, Indonesia

Infectious disease is a major burden in tropical countries like Indonesia. To reduce the transmission when certain pathogens are spreading in an area, early case detection and fast mobilization of resources are needed. Maps are commonly used to depict where infectious disease cases most frequently occur. Geographic Information System (GIS) technology, an open source software, has greatly increased the speed and accuracy which spatial information on infectious disease cases can be collected, integrated with other information to obtain the dynamic of pathogen transmission, and easily accessed by users in limited resource setting. To have a better understanding of where the six most common infectious diseases were distributed in 7 large cities in Indonesia and the dynamic of the pathogens, data from acute febrile illness requiring hospitalization (AFIRE) study were used. These data included GPS coordinate of participants' address, date of fever, onset of illness, and probable pathogens, which were identified by blood culture, molecular and serology assays. 823 from 1486 subjects had etiology confirmed with dengue (483 cases), *Rickettsia typhi* (103 cases), *Salmonella spp.* (103 cases), influenza (68 cases), *Leptospira spp.* (44 cases), and chikungunya (37 cases) as the most prevalent pathogens. Each case was grouped by date of illness and plotted based on coordinate of the address using open source GIS. Dengue cases were scattered in all areas of the cities, whereas *R. typhi* and *Leptospira spp.* cases were clustering in the center. Sporadic transmission occurred for three most prevalent viruses, dengue, chikungunya and influenza. Dengue serotypes were distributed through the year, with one serotype dominating for a specific duration before being replaced by the other serotypes. The application of GIS for integration of health surveillance systems proven to be useful tool to provide real-time information regarding the pathogens dynamic transmission in Indonesia. If the health providers aware of the prevalence and spatial distribution of the disease within their communities, an early detection could occur thus improve the health outcomes.

PUBLICATION RATES OF ABSTRACTS PRESENTED AT THE AMERICAN SOCIETY OF TROPICAL MEDICINE AND HYGIENE ANNUAL MEETINGS

Jhonatan R. Mejia[1], Ángel J. Quincho-Estares[1], Jessica E. Barrientos-Cochachi[1], **Antonio M. Quispe**[2]

[1]Facultad de Medicina Humana, Universidad Nacional del Centro del Perú, Huancayo, Peru, [2]Johns Hopkins Bloomberg School of Public Health, Lima, Peru

Annual research meetings represent an important opportunity for researchers to share their research and obtain feedback, previous its publication. However, a significant fraction of the abstracts accepted at these meetings is never published. We aimed to determine the publication rates of abstracts presented at the American Society of Tropical Medicine and Hygiene (ASTMH) annual meetings in the last decade. We performed a retrospective cohort study and assessed a random sample of the totality of abstracts presented at the ASTMH Annual Meetings (2008-2014). The study outcome was the publication rate in peer-reviewed journals indexed in Pubmed, Scopus, Embase, or Web of Science using first author last name and the primary medical subject heading term. Covariates of interest included study design, number of authors, first author's affiliation, first author's affiliation' country, year of publication, journals metrics, and institution. A random sample of 2,564 abstracts was obtained (~20%, N=12,875), for an average of 1,839±318 abstracts per annual meeting. Of these, around 25±1% were accepted for oral presentations. The overall publication rate was 46% (95% Confidence Interval, 38-53%) with no tendency to increase (p-value=0.34). This publication rate seems to be positively associated with the study design (Experimental vs. Observational studies), number of authors (more than five authors vs. five or less), and journal (AJTMH vs. Other); but negatively associated with the first author's affiliation (Public vs. non-public), first author's affiliation' country (High-income countries vs. low/middle-income countries), and type of abstract (oral vs. poster). However, at the multivariable model most important predictors of publication rate was an oral presentation (55% vs. 43%, RR 1.3, 95%CI 1.2-1.4) and experimental design (67% vs. 40%, RR 1.7, 95%CI 1.5-1.8). The publication rate of the abstracts accepted at the ASTMH seems to be low and steady in the last decade, which seems to be related to a variety of factors including study's design and oral presentation.

1520

WHAT WOMEN WANT DURING INSTITUTIONAL DELIVERY: EXPLORING THE DIS-UTILITIES ASSOCIATED WITH ATTRIBUTES OF DISRESPECT AND ABUSE DURING INSTITUTIONAL BIRTH

Nasir Umar, Tanya Marchant

London School of Hygiene & Tropical Medicine, London, United Kingdom

Achieving universal health coverage, an important part of sustainable development goals, will require not only that health services are

available, but people would want to access the services. Recent studies have highlighted the relationship between disrespect and abuse during institutional delivery and women willingness to subsequently access health care in health facilities. This study explored the values women attached to attributes of respectful care. We conducted a cross-sectional study of women with recent facility birth 0-6months in Gombe state Nigeria. We assessed their preferences for different attributes of respectful maternity care using discrete choice experiment. Women preferences for place of delivery and willingness to deliver in a health facility are strongly and negatively associated with attributes of dis-respect and abuse during institutional birth, including poor communication such as not informing the woman what is being done to her or what to expect during labour, allowed to ask question or being answered to politely during labour and delivery (B – 0.82, p <0.000), denied safe traditional birth practices during labour and delivery (B – 1.70, p <0.00), non-supportive care (B – 0.59, p <0.005). Women attached strong dis-utility to shortage of staff or the likelihood of not meeting a health worker (B – 2.08, p <0.000). In conclusion, our results suggest that women have a clear and strong negative preferences for attributes of disrespect and abuse practices during institutional delivery. Understanding and recognizing these preferences may be particularly useful in designing effective interventions aimed at increasing the demand and delivery of quality and respectful maternity care.

A QUALITATIVE STUDY OF BARRIERS AND ENABLERS TO THE ESTABLISHMENT OF ROBUST CLINICAL RESEARCH DATA MANAGEMENT SYSTEMS IN LOW AND MIDDLE INCOME COUNTRIES

Amélie M. Julé[1], Magatte Ndiaye[2], Oumar Gaye[2], Félix Koukouikila[3], Francine Ntoumi[3], Piero L. Olliaro[4], Philippe J. Guérin[5], Trudie A. Lang[6], Vicki Marsh[7]

[1]Centre for Tropical Medicine and Global Health, University of Oxford, Oxford, United Kingdom, [2]Service de Parasitologie et Mycologie, Université Cheikh Anta Diop, Dakar, Senegal, [3]Fondation Congolaise pour la Recherche Médicale, Brazzaville, Republic of the Congo, [4]Special Programme for Research and Training in Tropical Diseases (TDR), World Health Organization (WHO), Geneva, Switzerland, [5]WorldWide Antimalarial Resistance Network (WWARN) and Infectious Diseases Data Observatory (IDDO), Oxford, United Kingdom, [6]The Global Health Network, Oxford, United Kingdom, [7]Kenya Medical Research Institute (KEMRI), Nairobi, Kenya

Data Management (DM) is an essential component of clinical research, which is however poorly developed, especially in Low and Middle Income Countries (LMICs). Strengthening capacity for DM is essential, so that investigators in LMICs have the skills and resources to organise and analyse their data, and to use the information to guide policy, while also responding to increased demands for data sharing. While the need to understand the barriers and enablers to the establishment of robust clinical research Data Management Systems (DMS) is clear, little empirical research has been performed on this topic, particularly in LMICs. We therefore have conducted a qualitative study, recruiting participants in Dakar, Senegal and Brazzaville, Republic of the Congo. Our objective was to explore the current DM practices and to identify areas where additional training and resources are most needed. We have interviewed eight to twelve clinical research staff involved in data management or quality control at each site. Data from these in-depth interviews were complemented by informal conversations with key informants, and by observations made by the primary researcher (and interviewer) during an immersive fieldwork period of 3-4 weeks at each site. Our findings confirm that running robust DMS requires adequate financing and the existence of strong Information and Technology (IT) infrastructure (the 'hard components' of the DMS). More importantly, they highlight the significance of 'soft components', including good communication and social interactions among those involved in clinical research DM. Our data also emphasise the necessity to establish DM as a recognised and valued professional role in academia and disease control programmes; as well as the need to raise awareness of the complexity of this field and of the critical role of well-trained data managers. We will discuss the contribution of these findings to strengthening clinical research DM capacity in similar LMIC settings.

1522

MULTI SECTORAL APPROACHES TO PREVENT AND CONTROL MALARIA AND ARBOVIRAL DISEASES

Konstantina Boutsika[1], Florence Fouque[2], Zee Leung[3], Karin Gross[4]

[1]Swiss TPH, Basel, Switzerland, [2]WHO/TDR, Geneva, Switzerland, [3]International Development Research Centre, Ottawa, ON, Canada, [4]Swiss Agency for Development and Cooperation, Bern, Switzerland

Vector-Borne Diseases (VBDs) including malaria and emerging arboviral diseases account of about one quarter of all infectious diseases. Although some progress has been seen for malaria, other diseases such as those caused by arboviruses such as Dengue, Chikungunya, Yellow fever and more recently Zika, are expanding, with increased number of cases and fatalities.It has become evident that the prevention and control of these diseases have to go beyond health and to include more than a single sector approach since the transmissions patterns are driven by vector-host-pathogen- relationships which dynamically interact with natural conditions, human societies and vector parameters. The importance of multi sectoral collaborations has, therefore, been unanimously been recognized by countries when approving the Global Vector Control Response (GVCR) at the 70th World Health Assembly in May 2017. The GVCR includes multi-sectoral approaches as one the four pillars to develop an appropriate and sustainable response. The Swiss Agency for Development and Cooperation (SDC), the Canada' International Development Research Centre (IDRC), the Swiss Tropical and Public Health Institute (STPH) and the Vector Environment and Society Unit of TDR/WHO have joined forces with the ultimate aim to build a conceptual framework for multi sectoral approaches to prevent and control malaria and emerging arboviral diseases based on available evidences and subsequent implementation case studies. In a first step, five scientific reviews were commissioned to explore the landscape of the multi-sectoral approaches for the prevention and control of vector-borne diseases. In a second step, we now aim to use the available evidences to discuss priorities topics for implementation activities, and - on this basis - to develop a conceptual framework to provide to stakeholders some guidelines on how to develop multi-sectorial VBDs control.

1523

COMMUNITY-BASED SURVEILLANCE OF NOTIFIABLE DISEASES THROUGH THE STRATEGY OF COMMUNITY WATCH AND ALERT COMMITTEE (CWAC) IN SENEGAL

Fatou C. Niang[1], Chrestien Yameni[1], Suzanne Van Hulle[2], Coraldine Roka Loko[3], Kristina Sene[1]

[1]Catholic Relief Services, Dakar, Senegal, [2]Catholic Relief Services, Baltimore, MD, United States, [3]Centers for Disease Control and Prevention, Dakar, Senegal

Early response to an epidemic, depends on early detection, which cannot be done without effective involvement of the community. In Senegal, an external joint evaluation, highlighted shortcomings in the national surveillance system, including those at the community level. Catholic Relief Services, with funding from the CDC, supports the Ministry of Health and Social Services' (MHSS) priority of strengthening community disease surveillance. In Diourbel region, community surveillance of diseases, having epidemic outbreak potential, is managed through the Community Watch and Alert Committee (CWAC) strategy. Each CWAC member investigates suspected cases of 1 of 8 diseases under surveillance (cholera, yellow fever, measles, neonatal tetanus, bloody diarrhea, poliomyelitis, meningitis and Ebola), or any unusual event/rumor, according to community case definitions. Identified alerts are immediately notified by telephone to

the Head of Health Post known as "Infirmier Chef de Poste" (ICP) who will carry out the necessary investigations within 48 hours to confirm or cancel the alert. Once the alert is confirmed, the ICP will follow instructions from the central level for the management of suspected cases, including removal of the suspected case to transport of samples to the reference laboratory for analysis. Program activities include training of community actors, regular supervision, and an evaluation after 6 months of implementation to share the results, and better understand the level of national ownership at all levels of the health system.After six months of implementation, 108 alerts were received. The top 5 disease alerts included: Bloody diarrhea: 50 alerts (42 investigated and 30 confirmed suspected cases); Cholera: 16 alerts (16 investigated and 0 confirmed); Measles: 14 alerts (12 investigated and 5 confirmed suspected cases); Yellow fever: 13 alerts (12 investigated and 10 confirmed suspected cases); and, Poliomyelitis: 5 alerts (4 investigated and 4 confirmed suspected cases). Strengthening surveillance at the community level has enabled the Diourbel Region to improve its performance in epidemiological surveillance.

1524

STRENGTHENING THE HEALTH INFORMATION SYSTEM IN GUINEA

Donatien Ntambue

Catholic Relief Services, Conakry, Guinea

Management of health information remains a thorny problem to ensure quality, promptness and completeness of health data for efficient decision making in West Africa. In 2014, the evaluation of the National Health Information System (NHIS) of Guinea, according to the PRISM (Performance of Routine Health Information System Management) approach, revealed the following weaknesses: absence of strategic and normative documents; absence of an electronic tool for data management; only about 20% of health reports were complete; absence of standard and harmonized data collection tools; and, no effective supervisions, all leading to a weak system unable to provide health information in real time. To address these issues and strengthen the health information system, Catholic Relief Services provided support focusing on 3 key areas: 1. Strengthening normative frameworks such as: the 2016-2020 National Health Information System Strategic Plan; developing a catalog of indicators for the health sector; manual of procedures for data management; as well as, monitoring tools focused on the Health Information System. 2. Strengthening routine data collection with the establishment of the DHIS2 national deployment management team. This resulted is 320 managers trained on DHIS2 (7 on Level 1 in Lomé), 260 executives trained in basic computer science and 2 in advanced DHIS2 in Oslo. 3. Capacity strengthening of operations in terms of various equipment. This support enabled the deployment of the DHIS2 and the data capture from 2015 to 2017. The rate of national level supervision on the function and us of the HMIS increased from 0% at the end of 2015 to 80% at the end of 2017, and data completeness improved from 20% to 97% at the end of 2017. The country now has standardized data collection tools, harmonized and available at each level of the health pyramid, and all health entities report in the DHIS2 software. Two challenges remain: the existence of parallel software systems by some of Ministry programs, and the inadequate use of DHIS2 data for decision-making. To address these challenges, discussions are underway to allow programs to migrate to DHIS2.

1525

MULTI-LOCUS SEQUENCE TYPING OF THE SHEEP TICK *IXODES RICINUS* AND ITS SYMBIONT *CANDIDATUS* MIDICHLORIA MITOCHONDRII ACROSS EUROPE REVEALS EVIDENCE OF LOCAL COEVOLUTION IN SCOTLAND

Alaa M. Al-Khafaji[1], Simon R. Clegg[2], Alice C. Pinder[1], Kayleigh M. Hansford[3], Frederik Seelig[4], Ruth E. Dinnis[4], Gabriele Margos[4], Jolyon M. Medlock[3], Edward J. Feil[4], Alistair C. Darby[1], John W. McGarry[1], Lucy Gilbert[5], Olivier Plantard[6], Davide Sassera[7], **Benjamin Makepeace**[1]

[1]University of Liverpool, Liverpool, United Kingdom, [2]University of Lincoln, Lincoln, United Kingdom, [3]Public Health England, Salisbury, United Kingdom, [4]University of Bath, Bath, United Kingdom, [5]James Hutton Institute, Aberdeen, United Kingdom, [6]Oniris, Nantes, France, [7]University of Pavia, Pavia, Italy

Ticks have complex microbiomes, but only a small proportion of the bacterial symbionts recorded from ticks are vertically transmitted. Moreover, co-cladogenesis between ticks and their symbionts, indicating an intimate relationship over evolutionary history driven by a mutualistic association, is the exception rather than the rule. One of the most widespread tick symbionts is *Candidatus* Midichloria, which has been detected in all of the major tick genera of medical and veterinary importance. In some species of *Ixodes*, such as the sheep tick *Ixodes ricinus* (infected with *Ca*. Midichloria mitochondrii), the symbiont is fixed in wild adult female ticks, suggesting an obligate mutualism. However, almost no information is available on genetic variation in *Ca*. M. mitochondrii or possible co-cladogenesis with its host across its geographic range. Here, we report the first survey of *Ca*. M. mitochondrii in *I. ricinus* in Great Britain and a multi-locus sequence typing (MLST) analysis of tick and symbiont between British ticks and those collected in continental Europe. We show that while the prevalence of the symbiont in nymphs collected in England is similar to that reported from the continent, a higher prevalence in nymphs and adult males is apparent in Wales. In general, *Ca*. M. mitochondrii exhibits very low levels of sequence diversity, although a consistent signal of host-symbiont coevolution was apparent in Scotland. Moreover, the tick MLST scheme revealed that Scottish specimens form a clade that is partially separated from other British ticks, with almost no contribution of continental sequence types in this north-westerly border of the tick's natural range. The low diversity of *Ca*. M. mitochondrii, in contrast with previously reported high rates of polymorphism in *I. ricinus* mitogenomes, suggests that the symbiont may have swept across Europe recently via a horizontal, rather than vertical, transmission route.

1526

ENTOMOLOGIC INVESTIGATIONS OF RE-EMERGING CHIKUNGUNYA OUTBREAKS IN MOMBASA CITY, KENYA, 2018

Joel Lutomiah[1], Hellen Koka[2], Edith Koskei[2], Albert Nyunja[2], James Mutisya[2], Francis Mulwa[2], Samuel Owaka[2], James Mancuso[2], Fredrick Eyase[2], Rosemary Sang[1]

[1]Kenya Medical Research Institute, Nairobi, Kenya, [2]United States Army Medical Research Directorate-Kenya, Nairobi, Kenya

Chikungunya virus (CHIKV) is a mosquito borne Alphavirus, primarily transmitted by *Aedes aegypti* and *Ae. albopictus*. The first major chikungunya outbreak in Kenya was in 2004-2005. Since then, no transmissions were reported until a resurgence of the virus in Mombasa city in 2017. Entomologic investigations were conducted in January 2018 to determine mosquito spp. causing the outbreak, identify breeding sites associated with the vectors and estimate vector densities. BG-sentinel and CDC light traps were set during the day and night to collect adult mosquitoes which were processed and screened for CHIKV. Residential houses were stratified and water holding containers inside and outside of dwellings inspected for immatures of *Ae. aegypti*. Breeding habitats and

their locations were determined and container index (CI), house index (HI), breteau index (BI), pupal index (PI) and pupae per person index (PPI) calculated. A total of 6940 adult mosquitoes were collected by BG sentinel (91%) and CDC light traps (9%) identified to species and analyzed for infection. *Culex pipiens* were the most abundant (69%), *Ae. vittatus* (14%) and *Ae. aegypti* (13%). CHIKV was isolated from a pool of *Ae. aegypti* mosquitoes. A total of 131 houses with a population of 547 households were surveyed, representing mean population of 4.2/house. 528 immature mosquitoes were collected comprising *Ae. aegypti* (n=524;99.2%), *Ae. vitattus* (n=2;0.4%) and *Cx. pipens* (n=2;0.4%). *Ae. aegypti* immatures were observed in 48 houses (HI=37) and 70 out of 668 water containers (CI=11;BI=53). 70 pupae were collected representing pupal index of 53 and PPI of 0.53. Jerry cans were the predominant containers inspected (n=437;65%) but plastic drums (n=127) recorded the highest positivity rate (35%) and plastic tanks (n=115;20%) for immatures. Indoor and outdoor containers were positive with no significant difference in positivity (*P<0.05*). The risk of chikungunya transmission in Mombasa city was high and therefore vector control programs should be initiated to reduce vector population. The role of *Ae. vittatus* in CHIKV transmission needs to be investigated.

1527

SALIVARY AND ANTENNAL TRANSCRIPTOMES OF *CIMEX LECTULARIUS* AND FUNCTIONAL STUDIES OF SALIVARY NITROPHORIN

Austin L. Drury, Travis C. van Warmerdam, Federico Hoffman, Jerome Goddard, Jonas King

Mississippi State University, Starkville, MS, United States

Cimex lectularius, the bed bug, was nearly eradicated in the developed world shortly after World War II using DDT and other pesticides. A recent resurgence of bedbug infestations in urban areas of developed countries has caused concern among the public and researchers. Although *C. lectularius* is not known to transmit pathogens to humans, they do elicit a type I hypersensitivity reaction known as cimicosis. *Cimex* salivary proteins, including nitrophorin, have been linked to cimicosis, but the mechanism is still unknown. Using an Illumina-based RNA-seq analysis we characterized the differentially expressed transcripts of the salivary glands of *C. lectularius*. This data offers insight into the major transcripts expressed in the salivary glands of bed bugs and identifies targets for potential knock down screening. Results from RNAi trials indicate notably high silencing efficiency of salivary nitrophorin using double-stranded RNA and ongoing *in vivo* studies aim to to shed light on the immunological connection between *Cimex* salivary nitrophorin and cimicosis. A parallel study is underway to complete the first global analysis of the *Cimex* antennal transcriptome and an update on current progress will be included.

1528

DISTRIBUTION OF TICK SPECIES COLLECTED FROM SEVEN SITES IN NORTHERN AND SOUTHERN AREAS OF GHANA

Danielle Ladzekpo[1], Charlotte A. Addae[1], Janice A. Tagoe[1], Joseph W. Diclaro II[2], Andrew Letizia[3], Seth Offei Addo[1], Mba-Tihssommah Mosore[1], Eric Behene[1], Mawuli Dzodzomenyo[4], Shirley Nimo-Paintsil[3], Samuel K. Dadzie[1]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]Navy Entomology Center of Excellence, Jacksonville, FL, United States, [3]United States Naval Medical Research Unit No. 3, Ghana Detachment, Accra, Ghana, [4]School of Public Health, University of Ghana, Accra, Ghana

Ticks are important vectors and reservoirs for many zoonotic disease-causing pathogens worldwide. Africa has nearly 50 endemic tick species that are noted to infest domestic animals and livestock with the genera *Amblyomma, Rhipicephalus* and *Hyalomma* known to have the health effects on livestock among these endemic species in Africa. Some African countries have reported tick-borne infections like Crimean-Congo haemorrhagic fever including Ghana. However, there is scarce information on the diversity and distribution of the tick vector in Ghana. Identification of tick species and knowledge of their densities is critical for an effective vector control program. The distribution of arthropods is generally known to be influenced by environmental factors such as rainfall, humidity, temperature and vegetation thus ticks were collected from cattle, sheep and dogs within two ecological zones in Ghana (northern sahel savannah and coastal savannah) was assessed. A total of 1,925 ticks were collected from seven sites and morphologically identified. The combined results showed that *Amblyomma* (60.94%)*, Rhipicephalus (30.55%)* and *Hyalomma (8.51%)* genera were predominant in the study sites. 1240 ticks were collected in the northern sahel, which included four sites with Navrongo and Tamale, the species distribution was Amblyomma (60.6%), Rhipicephalus (28.5%) and Hyalomma (10.9%). 685 ticks were collected in the coastal savannah, which included three sites in Accra, Afienya and Shai Hills and the species distribution was Amblyomma (61.46%), Rhipicephalus (34.3%) and Hyalomma (4.24%). The *Amblyomma variegatum (60.94%)* species was the most common in both ecological zones. *Amblyomma variegatum* in addition to having a high impact on livestock health and productivity has been implicated in the transmission of tick-borne pathogens such as Crimean-Congo haemorrhagic fever virus and Dugbe virus, both of which have been isolated in Ghana. The prevalence of these three genera of ticks in the study sites highlight the need for continuous tick surveillance to give a clearer understanding of vector dynamics for that will contribute to a control strategy.

1529

FIRST REPORT OF SAND FLIES NATURALLY INFECTED WITH *LEISHMANIA NAIFFI* AND *BARTONELLA* SPP. IN THE PERUVIAN AMAZON

Marisa E. Lozano[1], Liz J. Espada[1], **Victor O. Zorrilla**[1], Michael Y. Kosoy[2], Clifton D. McKee[2], Lynn M. Osikowicz[2], Heriberto Arevalo[3], Mario Troyes[4], Craig A. Stoops[1], Michael L. Fisher[1], Gissella M. Vasquez[1]

[1]U.S. Naval Medical Research Unit No. 6, Bellavista, Peru, [2]Centers for Disease Control and Prevention, Fort Collins, CO, United States, [3]San Martin Regional Health Directorate, San Martin, Peru, [4]Jaen Health Directorate, Jaen, Cajamarca, Peru

In Peru, *Lutzomyia verrucarum* and *Lu. peruensis* are known vectors of cutaneous leishmaniasis and bartonellosis in the Andean region. However, there is limited or no information regarding sand fly vectors of these diseases in the Amazon region. In this study, we carried out sand fly collections from lowland and highland jungle areas of the Peruvian Amazon and tested them for *Leishmania* and *Bartonella* DNA. Sand flies were collected from Madre de Dios (292 m.a.s.l.) in July 2014, San Martin (421 m.a.s.l), and Cajamarca (1,231 m.a.s.l) in January 2015 using CDC light traps and Mosquito Magnet trap. A total of 277 female sand flies from Madre de Dios, 153 from Cajamarca, and 611 from San Martin were pooled by species, site, and trap type (1-10 individuals per pool) for molecular screening. *Leishmania* detection was performed by kDNA PCR followed by nested cytB PCR and sequencing. *Bartonella* screening was performed by ITS PCR followed by nested gltA PCR and sequencing. Seven of 48 pools (0.03 infection rate) from Madre de Dios and 11 of 146 pools (0.02 infection rate) from San Martin were kDNA PCR positive for *Leishmania* spp. One *Lutzomyia hirsuta* pool from San Martin was found infected with *Leishmania naiffi* and one *Lu. carrerai* pool from Madre de Dios with *L. guyanensis*. Two of 48 pools (0.01 infection rate) from Madre de Dios, 17 of 146 pools (0.03 infection rate) from San Martin, and 2 of 43 pools (0.01 infection rate) from Cajamarca were ITS/gltA PCR positive for *Bartonella* spp. One *Lutzomyia nevesi* pool from San Martin and one *Lu. maranonensis* pool from Cajamarca were positive for *Bartonella* DNA closely related to *Candidatus* B. rhondoniensis found in triatomine bugs from French Guiana. Seven *Lutzomyia nevesi* pools and two *Lu. hirsuta* pools from San Martin, and one *Lu. whitmani* pool from Madre de Dios were positive for *Bartonella* DNA closely related to *B. bacilliformis*. Molecular screening with additional markers will confirm *Bartonella* and *Leishmania* species. This is the first report of *Leishmania naiffi* and

Bartonella spp. molecular detection in sand flies from the Peruvian Amazon, suggesting that these pathogens may be circulating in this region of Peru.

1530

PROFILES AND SWARM DYNAMICS IN *ANOPHELES GAMBIAE* MOSQUITOES AT SELECT TARGET MALARIA STUDY SITES

Danspaid M. Paul.[1], Krystal Birungi[1], Matilda C. Collins[2], Jonathan Kayondo[1]

[1]Uganda Virus Research Institute, Etebbe, Uganda, [2]Imperial College London, London, United Kingdom

The *Anopheles gambiae* complex (*s.l.*) is the major Afro-tropical vector of malaria. Innovative methods, including genetic modification and sterile male techniques are being developed to precisely target such malaria vectors. Estimation of the proportion of male and female mosquitoes sampled is also vital for monitoring and control purposes but due to none or limited surveillance in East Africa little is known anopheles swarm. This requires detailed understanding of current mosquito diversity, abundance, sex ratio, mating behaviour and dynamics in different ecological environments. This baseline study was aimed at identifying factors that enhance swarming and collection of *An. gambiae s.l.* male populations at three mainland sites for the target malaria project in Uganda. Mosquito swarms were surveyed by local trained volunteers from March 2017 to date in three villages Kibbuye, Katuuso and Kayonjo in Uganda. Aspiration of house eaves was done in the morning. Swarm markers were identified and sweep nets were used to sample. Swarms GPS location was mapped. A total of 113 *Anopheles* swarms were identified, characterized and mapped. Mean swarm height was 2.6m and common markers included bare ground, roads, abandoned bricks covered with grass and sand. 70% of swarm were collected from bare ground grass thatched compound and there was high number of swarm during rainy season. Aspiration of eaves especially grass thatched houses as a location of swarm in time of low density is very important. The study also hopes to promote open dialogue with community members on existing and promising strategies on identification of mosquito swarms.

1531

SPATIAL ANALYSIS OF TRANSPORT NETWORKS IN NORTHERN UGANDA FOR GUIDING VECTOR CONTROL ACTIVITIES FOR SLEEPING SICKNESS

Michelle C. Stanton[1], Joshua Longbottom[1], Ana Krause[2], Johan Esterhuizen[2], Steve J. Torr[2]

[1]Lancaster University, Lancaster, United Kingdom, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Sleeping sickness, also known as human African trypanosomiasis (HAT), is a disease transmitted by the bite of a tsetse fly. Control of Gambian sleeping sickness, the most common form of HAT, is primarily achieved through active and passive surveillance and subsequent treatment plus vector control. A cost-effective method of controlling riverine species of tsetse that transmit Gambian sleeping sickness is to deploy insecticide-impregnated '*tiny targets*' in high transmission risk areas. These targets have been shown to reduce the tsetse population by over 90%, hence significantly reducing the risk of sleeping sickness transmission. In areas where the intervention is implemented, traps are used to monitor the tsetse population at regular intervals to evaluate the impact of the intervention on the tsetse population. As the intervention scales up to cover larger geographical areas, maintaining a cost-effective monitoring programme becomes more challenging. This study therefore focussed on the logistical challenges associated with tsetse monitoring within an historical HAT focus in north-west Uganda. Staff involved in the monitoring programme were requested to record GPS data during their monitoring activities over six weeks which enabled accurate information on travel routes and speeds to be established. Additional travel network data (locations of roads, category of road) were also obtained from OpenStreetMap plus through image classification of high resolution (<3m) remotely sensed images. Using this information, friction surfaces representing the time-cost of travelling along each section of road within the area covered by the monitoring programme were developed. A 'least-cost path' analysis was then undertaken to estimate the travel times between key locations within the study area and current and proposed tsetse monitoring locations. This resource has the potential to improve the planning of monitoring activities within the current intervention area. Further, the methods used to establish the friction surfaces can be extrapolated to assist in the expansion of the tsetse plus other vector control programme to new areas.

1532

CHARACTERIZING WILDLIFE, DOMESTIC ANIMALS, AND HUMANS AS SOURCES OF TRIATOMINE BLOODMEALS: COMPARISON OF SANGER SEQUENCING AND AMPLICON DEEP SEQUENCING

Sujata Balasubramanian, Rachel Curtis-Robles, Bhagath Chirra, Lisa D. Auckland, Charles D. Johnson, Richard P. Metz, Shichen Wang, Gabriel L. Hamer, Sarah A. Hamer

Texas A&M University, College Station, TX, United States

Knowledge of host associations of blood-feeding vectors may afford novel insight for managing disease systems in order to protect public health. Triatomine insects vector the causal agent of Chagas disease, *Trypanosoma cruzi*. Across the southern US, this parasite is mainly transmitted among triatomines and wildlife, with occasional spillover into humans and domestic animals. We used two methods—Sanger sequencing and amplicon deep sequencing—to characterize the vertebrate host community previously fed upon by these insects. A collection of 119 triatomines from across Texas were dissected, and the amount of visible blood in the hindgut was scored. DNA was extracted from the hindgut, and PCR amplification of a 228bp region of vertebrate cyt *b* was completed. 37 (31.1%) samples produced amplicons of the target size successfully sequenced by Sanger. The frequency of success was significantly higher (OR 4.8, CI 2.0-13.2, $p<0.001$) in recently fed bugs vs. those with desiccated bloodmeals. Sanger sequencing revealed 15 distinct host species, which included domestic animals (e.g., dogs, chickens, cats, cows), wildlife (e.g. rats, raccoons, ringtails, crickets), and humans. Illumina MiSeq amplicon deep sequencing on the same PCR products (average of >172,000 usable reads per triatomine sample) replicated the host community data set found using Sanger sequencing, but also afforded detection of multiple hosts in 5 (13.5%) triatomines, including a triatomine with four detected bloodmeal sources (toad, human, dog and squirrel). Current efforts are underway for amplicon deep sequencing of bloodmeal hosts from 400 additional vectors collected in domestic, peridomestic, and sylvatic environments across the southern states for which *T. cruzi* infection status and parasite strain are already known, affording a robust assessment of host associations in relation to infection parameters. An enhanced understanding of vector-host-parasite networks may allow for integrated vector management programs to target interventions specific to highly-utilized and highly-infected host species.

1533

SURVEILLANCE OF *AEDES AEGYPTI* IN SIERRA LEONE, WEST AFRICA

Christopher Sandi[1], Samuel Juana Smith[2], Lucrecia Vizcaino[3], Audrey Lenhart[3], Matthew Burrows[3], Rebecca Levine[3]

[1]Emory University, Atlanta, GA, United States, [2]Ministry of Health and Sanitation, Freetown, Sierra Leone, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States

The prevalence of arboviral diseases transmitted by *Aedes aegypti* mosquitoes in West Africa has increased dramatically in recent years, with large outbreaks of Dengue, Yellow Fever, and Chikungunya reported

throughout most of the region. However, very little basic entomological information is known about the vector in the region, which limits the ability to prevent and control their spread and hence transmission of these viruses. Therefore, we performed an entomological survey of *Ae. aegypti* in Sierra Leone, where it has not been studied before. Between June and August 2017, we conducted egg, immature, and adult sampling of *Ae. aegypti* in two locations in Sierra Leone (Bombali and Bo Districts). Eggs were counted to determine densities and then used to rear adults in the insectary. Lab-reared females were tested for resistance to six different insecticides as well as for the prevalence of knock-down resistance (KDR) genotypes. Immature sampling was done to identify breeding sites and calculate standard *Ae.* indices. Wild-caught adult females were preserved and tested for arboviruses. The mean eggs per trap was 23.7 while 58 adult females were captured. For immatures, indices were high in general, ranging from 13-17 for Container, 18-61 for house, and 65-153 for Breteau. Tires and bottles were the most common breeding sites, accounting for 44% and 20% (respectively) of all positive container types. Adults reared from eggs in both locations were 100% susceptible to Deltamethrin and resistant to Permethrin (53% mortality). Evidence of higher KDR genotypic frequencies among Permethrin-resistant mosquitoes was found in one of the locations (Bombali). Viral testing on adults for Flaviviruses and Chikungunya Virus was negative, however the sample size was small. A serosurvey conducted in one of the locations (Bo) in 2013 showed a high seroprevalence for Chikungunya, therefore, additional sample collection and testing is warranted. Further recommendations are to focus on tires and bottles for clean-up campaigns, and if chemical control measures begin for *Ae. Aegypti* in either location, they should use Deltamethrin and discontinue use of Permethrin.

1534

THE GEOGRAPHIC DISTRIBUTION OF SUSPECTED LYME BORRELIA IN MONGOLIA

Madeline Illar[1], Lkhunrev Rolomjav[2], Doniddemberel Altantogtokh[2], Kathryn M. Hogan[1], Nyamdori Tsohbadrakh[2], Baasandagya Uyanga[3], Dalantai Ganbold[2], Michael E. von Fricken[1]

[1]Department of Global and Community Health, George Mason University, Fairfax, VA, United States, [2]National Center for Zoonotic Diseases, Ulaanbaatar, Mongolia, [3]Division of Infectious Disease, Duke Global Health Institute, Duke University, Durham, NC, United States

In Asia, *Borrelia garinii, B. afzelii,* and *B. miyamotoi* are transmitted by the *Ixodes persulcatus* tick and clinically present with a wide range of neurological and arthritic symptoms. *B. garinii* has been reported to cause neuroborreliosis in Europe, Russia and China, but no studies to date have described the clinical manifestations of Lyme borreliosis (LB) in Mongolia. This case series examines 150 cases of suspected Lyme borreliosis in Mongolia from 2007 to 2017 to describe the frequency of symptoms, potential regions of interest, and case demographics associated with suspected LB. Data regarding sociodemographics, dates and origin of reported infection, clinical symptoms, and methods of diagnosis (IIFA and/or ELISA test) were collected from individuals across 13 aimags (provinces). Zavkhan and Selenge, located in northern Mongolia, where vegetation density is high, had the highest percentage of reported suspected cases, with 25% and 20% respectively. Ages ranged from 1 to 78 years old with a mean of 26 years, however 37% of individuals were under age ten. Most frequently reported symptoms include fever, rash, headache, and enlarged lymph glands. Peak months of tick bite and treatment seeking occurred between April and June. More than twice as many women sought treatment as men, and the distribution of men who sought treatment was skewed toward children and the elderly. LB surveillance and monitoring should be expanded in the northern region of Mongolia and be considered in differential diagnosis in those reporting a recent tick bite.

1535

MOLECULAR ANALYSIS OF TICK SPECIES IN COSTA RICA AND PANAMA

Rolando D. Moreira-Soto[1], Dione Palma-Carranza[1], Diana Rojas-Araya[1], Sergio Bermudez[2], Olger Calderon-Arguedas[1], **Adriana Troyo**[1]

[1]Universidad de Costa Rica, San Jose, Costa Rica, [2]Instituto Conmemorativo Gorgas de Estudios de la Salud, Panama City, Panama

Different tick species may vary in behavior and vector competence, so a correct identification is necessary to understand the epidemiology of tick-borne diseases. Analysis of gene sequences is a useful tool to confirm species and detect possible cryptic species. The aim of this study was to compare ticks from Costa Rica and Panama using the mitochondrial 16S rDNA gene. A fragment of the mitochondrial 16S rDNA gene was amplified (primers 16S+1 y 16S-1; 460 bp) from 93 tick samples from Costa Rica (16 species identified morphologically and unidentified samples) and 15 from Panama (9 species). DNA sequences were compared with sequences in GenBank, and phylogenetic trees were constructed. Results were complemented with amplification, sequencing, and analyses of cytochrome C oxidase subunit I (Cox-1) and internal transcribed spacer 2 (ITS2) gene fragments. Most 16S rDNA sequences obtained were highly similar (>99%) to corresponding sequences in GenBank: *Amblyomma calcaratum, A. geayi, A. naponense, A. nodosum, A. ovale, A. sabanerae, A. mixtum, A. dissimile, A. rotundatum, A. varium*, *Rhipicephalus sanguineus* s.l. (tropical lineage), *R. microplus, Dermacentor nitens, Ornithodoros knoxjonesi*. Sequences from *Amblyomma naponense* and *A. pecarium* from Panama had lower similarity to those available (98.7-99%). Two sequences of *Amblyomma oblongoguttatum* s.l. were 98.7% similar to sequences from Brazil, but another sequence was only 91.9% similar to it. Ticks identified as *A. parvum* and *Ixodes boliviensis* had sequences <94% similar to those from South America. Sequences of *Haemaphysalis yuxtakochi* were only 96.2% similar to a sequence from Uruguay. 16S rDNA sequences for *Amblyomma tapirellum* and *Dermacentor latus* were not available for comparison. Evaluation of Cox-1 and ITS2 gene fragments allowed confirmation of results. Phylogenetic analyses also showed similar relationships. Results showed possible intraspecific variations and cryptic tick species in the region. Detailed morphological and biological studies will be necessary to determine their final taxonomic status.

1536

MAPPING MALARIA RISK IN PACIFIC REGION OF COLOMBIA USING ENVIRONMENTAL VARIABLES RELATED TO THE INCIDENCE

Estefani A. Piedrahita-Hernández[1], Mariano Altamiranda-Saavedra[1], Carlos Marcelo Scavuzzo[2], Margarita M. Correa-Ochoa[1]

[1]Grupo de Microbiología Molecular, Escuela de Microbiología. Universidad de Antioquia, Medellín, Colombia, [2]Instituto de Altos Estudios Espaciales-Mario Gulich, Centro Espacial Teófilo Tabanera, CONAE, Córdoba, Argentina

Colombia ranks third in Latin America in the number of malaria cases. Currently, the Colombian Pacific is the main endemic region reporting more than 60% of total cases. Although, efforts have been made to map and categorize malaria risk at the municipality level, topographic and environmental complexities suggest the necessity to categorize malaria risk at a finer spatial scale. Therefore, this study aimed to the design a malaria risk map of the Colombia Pacific region and to the determination of the environmental variables influencing malaria incidence. The relationship of the variables NDVI, NDWI, TWI, precipitation and temperature with the annual parasitic index (observed API) was evaluated using a Generalized Linear Model (GLM). An incidence risk map at a spatial scale of 1 Km^2 was constructed through a Bayesian Logistic Regression analysis. A significant correlation was found for the incidence of malaria with the variables precipitation and NDVI (R^2 = 0.98, p <0.05). The moderate to high risk areas were located mainly in central Chocó Department, along the San

Juan and Atrato rivers, and in areas west of the Cauca river and Pacific lowlands of the Andes Mountains. A linear regression used to validate the model showed a statistically significant relationship between the observed and estimated API (R^2 = 0.86588, $p < 0.05$). Finally, the risk map obtained could be used to inform public entities of the malaria risk in particular places of this region, in order to optimize the economic resources allocated for vector control and surveillance.

1537

COMPARATIVE ANALYSIS OF THE SALIVARY N-GLYCOMES OF THREE NORTH AMERICAN TICK SPECIES

Gary Crispell, Shahid Karim

The University of Southern Mississippi, Hattiesburg, MS, United States

Ticks are parasitic arthropods of great medical and veterinary importance because of their capability of transmitting various viral and bacterial pathogens. We believe that the prolonged duration of tick feeding, as compared to other blood-sucking arthropods, contributes to their success as vectors. During attachment, there is an ongoing exchange of tick saliva and host blood, where the nutrients for tick growth are derived. We hypothesize that as the tick feeds, the salivary N-glycome is dynamic, possibly to mimic the host glycans and evade detection by the immune system. Tick saliva and salivary gland proteins were isolated from *Amblyomma americanum, Amblyomma maculatum*, and *Ixodes scapularis* ticks and then were reduced, alkylated, and digested with trypsin. Dried glycopeptides were incubated with Peptide-N-Glycosidase A (PNGase A) and PNGase F to release the N-linked glycans, and the glycans were then recovered by passing through a C18 sep pak cartridge. Analysis of the glycans present in tick salivary samples were performed using MALDI-TOF/TOF-MS. The N-linked glycan profiles of these three tick species have revealed a wealth of knowledge concerning the variation of tick salivary protein glycosylation during growth and feeding. We have noticed similarities of the profiles between the antennary structures and glycoforms of all assessed tick species, but the individual composition of each is unique. This research establishes a foundation to better understand the purpose of tick N-glycan synthesis during the blood meal.

1538

"CROSS-VECTOR MONITORING": UTILIZING MOSQUITO EXCRETA/FECES TO SCREEN FOR PATHOGENS VECTORED BY NON-MOSQUITO HOSTS

Nils Pilotte[1], Corrado Minetti[2], Darren A. Cook[2], Michael F. Zulch[1], Lisa J. Reimer[2], Steven A. Williams[1]

[1]Smith College, Northampton, MA, United States, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

By limiting biological mass, the molecular testing of mosquito-derived excreta/feces (E/F) has the potential to increase the throughput of xenomonitoring efforts and expand its utility for the sensitive screening of infectious agents. Equally promising, previous proof-of-concept work has exhibited the capacity for "cross-vector monitoring" as the real-time PCR-based detection of *Trypanosoma brucei brucei* DNA within the excreta/feces (E/F) of mosquitoes has been demonstrated following the provision of a *T. brucei*-positive bloodmeal. However, to date, the capability of this technique to serve as a methodology for the detection of non-mosquito vectored pathogens has not been evaluated using field-collected samples. Accordingly, human bloodspots, mosquitoes, and mosquito-derived E/F were collected from two rural communities in the Northern region of Ghana. Following DNA extraction, real-time PCR testing of mosquitoes and the corresponding E/F from those same mosquitoes resulted in the detection of *Mansonella ssp.* Detection of the same pathogen occurred following similar testing of DNA extracted from human bloodspots collected in the same region. This capacity to detect pathogens vectored by non-mosquito arthropods in the E/F of mosquitoes expands the utility of molecular xenomonitoring and increases the potential for integrated evaluation among various monitoring and evaluation programs. Furthermore, the adaptation of E/F testing to the detection of blood-borne pathogens altogether lacking a vector host should also be evaluated.

1539

RELATIVE VECTOR COMPETENCE OF *AEDES AEGYPTI* AND *AE. ALBOPICTUS* FOR AN EPIDEMIC STRAIN OF ZIKA VIRUS UNDER SIMULATED FIELD CONDITIONS

Leon E. Hugo[1], Liesel Stassen[2], Gregor J. Devine[1], Francesca D. Frentiu[2]

[1]QIMR Berghofer Medical Research Institute, Herston, Australia, [2]Queensland University of Technology, Brisbane, Australia

The major arbovirus vector *Aedes aegypti* was firmly implicated in the transmission of the Asian lineage of Zika virus (ZIKV) during the pandemic affecting French Polynesia and the Americas. However, the contribution of the invasive mosquito *Aedes albopictus* is more uncertain given varying estimates of the vector competence of this species. Mosquito vector competence depends on factors that include the compatibility of mosquito/virus strains and environmental variation. We determined the vector competence of an Australian strain of *Ae. aegypti* and a strain of *Ae. albopictus* threatening the Australian mainland, for a strain of ZIKV isolated from Joao Pessoa, Paraiba state, Brazil during the pandemic. We maintained mosquitoes under a natural cyclical temperature regime and a standard regimen of constant 28°C and tracked virus dissemination within mosquitoes over time by quantifying viral copy number, performing whole-mosquito immunofluorescence analysis, and testing for live virus in saliva. Overall, infection rates at 14 days post inoculation were 69.2% for *Ae. aegypti* and 90.0% for *Ae. albopictus* and viral dissemination rates to legs and wings were 56.4% and 70.0% for the two species, respectively. However, while 56.4% of *Ae. aegypti* had infectious virus in the saliva, the same parameter of transmission was only 15% for *Ae. albopictus*. Both species supported heavy viral loads indicated by means of $> 10^8$ copies per mosquito at 14 days and a characteristic 'saturated infection' pattern through most body tissues. However, there were significant differences in viral copy number at earlier time points between cyclical and constant temperature regimes. These results indicate the presence of a barrier to virus transmission for this strain of *Ae. albopictus*. However, the lower vector competence of *Ae. albopictus* should be factored in with its greater range when determining its contribution to ZIKV transmission.

1540

CHARACTERISTICS AND TREATMENT PATTERNS OF OUTPATIENTS WITH RICKETTSIAL DISEASES IN A LARGE, COMMERCIALLY INSURED POPULATION, UNITED STATES, 2005-2016

Alison M. Binder, Amy E. Peterson, Paige A. Armstrong

Centers for Disease Control and Prevention, Atlanta, GA, United States

Rickettsial diseases (RD) include Spotted Fever Group (SFG) Rickettsiosis, Ehrlichiosis, Anaplasmosis, Typhus Group (TG) and Rickettsialpox, among others. Doxycycline is the treatment of choice in all age groups, and early treatment based on clinical diagnosis is important to prevent severe and fatal outcomes. SFG, Ehrlichiosis, and Anaplasmosis are nationally notifiable in the United States, but data on treatment patterns are not collected. We conducted a retrospective analysis using Truven Health MarketScan® Commercial Claims and Encounters databases. We included any individual with an outpatient claim using an ICD-9/10-CM code for RD, who had one year continuous pre- and 3 months post-diagnosis enrollment and pharmaceutical claim data. The first outpatient record with RD was considered the incident diagnosis. Demographics, epidemiologic characteristics, and treatment patterns were summarized for all individuals. In total, 13,909 individuals were included; median age was 45 years (IQR: 28-55 years), 2141 (15%) were under 18 years of age, and 51% were

male. The most common diagnosis was SFG (7332; 53%), followed by Ehrlichiosis (4182; 30%), Typhus (1343; 10%), and other rickettsioses (1016; 7%); 36 individuals had more than one diagnosis. Over half (7512; 54%) received doxycycline within 30 of the index date; of these, 3690 (49%) received it within 14 days. The majority (5572; 74%) of adults received the recommended dose of 100mg; and the same amount were treated for at least 10 days. The proportion with a pharmaceutical claim for doxycycline varied considerably across diagnoses and ranged from 26% for TG to 61% for SFG Rickettsiosis. Among the 6397 (46%) without a claim for doxycycline, 2217 (35%) were prescribed another tetracycline or antibiotic; 3883 (28%) were not prescribed any antibiotic. RD continue to be an important cause of disease in the outpatient population, and yet providers are still only prescribing the recommended treatment to about half of those in whom they suspect the disease. Continued education and increased awareness is critical to prevent severe and fatal outcomes from RD.

1541

SITUATIONAL ANALYSIS OUTCOME OF SCABIES CONTROL PROGRAM IN ETHIOPIA

Mekdes Nigusse[1], Andrew Steer[2], Birhan Mengistu[1]

[1]Ethiopian Federal Ministry Of Health, Disease Prevention and Control Directorate, Addis Ababa, Ethiopia, [2]Murdoch Children's Research Institute, Melbourne, Australia

Scabies is an infestation of the skin caused by the human itch mite (*Sarcoptes scabiei* var. *hominis*). The microscopic scabies mite burrows into the upper layer of the skin where it lives and lays its eggs. Scabies imposes a considerable economic burden on individuals, families, communities, and health systems. Families in endemic areas spend a substantial portion of income on treatments, re-directing available funds for food and essential commodities. An analysis of the 2010 Global Burden of Disease study estimated the global prevalence to be 200 million cases. Scabies is also the major risk factor for impetigo in tropical countries. Following the inclusion of Scabies on the public health emergency reporting system in 2016, cases of scabies have been reported as a part of the country health reporting system. In 2017/18, cases of scabies were reported from the Amhara, Tigray, Oromia, Benishangulgumuz and Southern Nation and nationalities (SNNPR) regions. More than 704,210 people were affected with scabies in five regions of the country, with prevalence more than 10% in some districts. An in-depth assessment in Amhara region suggested limited knowledge of disease prevention, control and treatment aspects by different levels of health professionals. Absence of a standardized case definition further hinders the number of cases reported to the national level. Scabies has been included in the WHO NTD portfolio. Ethiopia established a scabies control program despite absence of standardized evidence for prevention and control strategies. Though scabies is common in many African countries, there is little evidence on the burden of the disease, treatment of choice, dosing, frequency, relationship with WASH and possibility of elimination. Therefore, attention on mapping protocols, clear case definitions, integrating with WASH activities and high level advocacy is needed for policymakers, donors and pharmaceutical companies in order to ensure universal accesses care coverage and breaking the neglect.

1542

DETECTION OF DUGBE VIRUS FROM TICKS IN ACCRA, GHANA

Charlotte A. Addae[1], Michael R. Wiley[2], Catherine Pratt[2], Seth O. Addo[1], Mba-tihssommah Mosore[1], Clara Yeboah[1], Bright Agbodzi[1], Danielle Danielle Ladzekpo[1], Janice Tagoe[1], Eric Eric Benehe[1], Courage Defeamekpor[3], Osbourne Osbourne Quaye[4], Shirley Nimo-Paintsil[5], Hanayo Arimoto[6], Andrew Letizia[5], Joseph W. Diclaro II[7], Samuel Dadzie[1]

[1]Noguchi Memorial Institute for Medical Resarch, Legon, Accra, Ghana, [2]Center for Genome Sciences, United States Army Medical Research Institute of Infectious Diseases (USAMRIID-CGS), Fort Detrick, MD, United States, [3]Ghana Army Veterinary Department, Accra, Ghana, [4]Department of Biochemistry Cell and Molecular Biology (WACCBIP), University of Ghana, Legon, Accra, Ghana, [5]United States Naval Medical Research Unit No. 3, Ghana Detachment, Accra, Ghana, [6]United States Naval Medical Research Unit No. 3, Cairo, Egypt, [7]Navy Entomology Centre of Excellence, Jacksonville, FL, United States

Dugbe virus is a negative sense RNA virus which belongs to the Nairobi sheep disease virus serogroup. The virus belongs to the family Nairoviridae and genus *Orthonairovirus*. It is transmitted by tick species of three genera; *Rhipicephalus, Amblyomma* and *Haemaphysalis.* The virus was first detected in domestic livestock from *Amblyomma variegatum* in Ghana. This study aimed to screen field collected ticks for the presence of Crimean-Congo haemorrhagic fever virus (CCHFV). Sampling was done in seven sites within Greater Accra, Northern and Upper East regions. A total of 927 ticks were collected from cattle, dogs, sheep and goats and morphologically identified using the African Ixodidae identification keys. Ticks were pooled by species, gender, study site and animal host. Pooled samples were homogenized using Mini Beadbeater-96 with lysis buffer. Nucleic acid was extracted using QIAamp Viral RNA Kit (QIAGEN, Valencia, CA, USA) following manufacturer's instructions. Extracts were screened for CCHFV using real time polymerase chain reaction. Three of the pools tested positive for CCHFV. The positive tick species were *Rhiphicephalus sanguineus* in Navrongo (sheep), *Hyalomma rufipes* in Shai Hills (cattle) and *Amblyomma variegatum* in Michel Camp (cattle). These pools were further analysed using next-generation sequencing targeted enrichment protocol developed by USAMRIID-CGS. Sequence alignment and phylogenetic analysis was done using MUSCLE and MEGA7 software respectively. Sequencing performed on all three pools failed to confirm presence of CCHFV however, the resulting data from one of the pools from Michel Camp, located outside Accra showed whole genome sequence of Dugbe virus. This pool may have initially tested positive for CCHFV because of the similarity in the S segment of nairoviruses. Phylogenetic analysis of the complete sequence of the Dugbe virus using Maximum likelihood tree algorithm showed a close relationship with the Dugbe strain previously found in Ghana and Nigeria. Further surveillance and characterization studies need to be conducted to determine the prevalence of the virus in Ghana.

1543

TICK-BORNE DISEASE IN SOUTHERN COASTAL ECUADOR: DETECTION OF ANTIBODIES TO SPOTTED FEVER GROUP RICKETTSIA IN FEBRILE INDIVIDUALS IN 2014-2015

Lorne Farovitch[1], Anna M. Stewart-Ibarra[2], Efrain Beltran-Ayala[3], Timothy P. Endy[4], Brian Leydet[5]

[1]University of Rochester, Rochester, NY, United States, [2]Department of Medicine and Center for Global Health and Translational Science, State University of New York Upstate Medical University, Syracuse, NY, United States, [3]Department of Medicine, Universidad Técnica de Machala, Machala, Ecuador, [4]Department of Microbiology & Immunology, State University of New York Upstate Medical University, Syracuse, NY, United States, [5]Department of Environmental and Forest Biology, State University

of New York College of Environmental Science and Forestry, Syracuse, NY, United States

Ticks (family: *Ixodidae* and *Argasidae*) transmit debilitating and often fatal diseases to people in both tropical and non-tropical settings throughout the world. The incidence of tick-borne diseases (TBDs) have been increasing globally due to several factors, including climate change and ineffective comprehensive TBD surveillance and prevention programs. In areas with limited resources, diagnostic testing of TBDs is often unavailable because of the large number of potential pathogens and the complexity and cost of available diagnostic assays. In this pilot study, we analysed human plasma samples from an ongoing arbovirus disease surveillance studies in Machala, a tropical coastal city in southern Ecuador. Samples were collected from individuals with acute febrile illness who attended 4 sentinel clinics operated by the Ministry of Health. Samples were screened for the presence of antibodies to tick-borne Spotted Fever group *Rickettsia*. We used an indirect enzyme immunoassay to detect IgG and IgM antibodies in 222 plasma samples. We found that 60/222 (27%) and 38/222 (17%) of specimens had positive or equivocal IgG responses, respectively. Although testing is still ongoing 15/184 (8%) and 13/184 (7%) samples had positive or equivocal IgM ELISAs respectively. Molecular studies are ongoing to identify the Rickettsia species most likely infecting humans in this region of Ecuador. Our findings suggest there is a potentially significant burden of TBD in this region that has been undiagnosed and untreated. To our knowledge, this is the first study of TBD in this region. The results highlight the importance of surveillance studies to detect TBDs and the need for novel low-cost diagnostics for TBDs.

1544

IDENTIFICATION AND CHARACTERIZATION OF RESISTANCE TO DELTAMETRINE IN TRIATOMINE BUGS FROM RURAL HOUSES OF PAMPA ARGENTINA, CHACO PROVINCE, ARGENTINA

Yanina Maza[1], Georgina Fronza[2], Sergio Wasilewsky[3], Patricia Lobbia[4], **Diego Weinberg**[5], Mariela Fabiani[1], Carolina Remón[4], Marcelo C. Abril[5], Gastón Mougabure Cueto[4], Paula Sartor[1]

[1]Programa de Chagas, Ministerio de Salud Pública, Chaco, Argentina, [2]Centro de Investigaciones de Plagas e Insecticidas. CIPEIN-CITEFA-CONICET, Villa Martelli, Argentina, [3]Programa de Chagas, Ministerio de Salud de la Nación, Ciudad de Buenos Aires, Argentina, [4]Centro de Referencia de Vectores, Ministerio de Salud de la Nación- CONICET, Córdoba, Argentina, [5]Fundación Mundo Sano, Ciudad de Buenos Aires, Argentina

Triatoma infestans resistance to insecticides has been reported in the Bolivian and Argentina Gran Chaco Region both at the macro and meso scale. The objective of this study was to characterize the current susceptibility to deltrametrine in triatomine bugs from the rural locality of Pampa Argentina, Chaco Province, Argentina. The transversal study was conducted in all the houses of the locality (n=121) were triatomine bugs were captured and flowable deltametrine was applied. Collected bugs were identified and sent to the laboratory for their analysis through a rapid test and a bioassay. The infestation rate obtained was 25.5% and the analysis of pyrethroid susceptibility showed resistance levels higher than 1000 (RR>1000). In a second stage, a community approach was conducted in order to inform the community of the findings, evaluate houses one by one, obtain demographic data through questionnaires and capture triatomine bugs to determine their toxicological status. A total of 106 houses were evaluated and 49 of them were positive for the presence of bugs (46.2%). Analysis of susceptibility to pyrethroids showed a homogenous distribution of resistant bugs. Alternative control strategies currently available are organophosphate insecticides that were rejected by both the local health team and the community. These results show the need of other alternative strategies that are effective and non-toxic for the inhabitants and their animals. The absences of such strategies will increase the abundance of triatomine bugs, promoting the transmission of Chagas Disease to the population and moreover, the dispersal of pyrethroid resistant insects to other localities.

1545

GENETIC DIVERSITY OF *ANAPLASMA* AND *EHRLICHIA* BACTERIA IN MONGOLIAN TICKS

Michael E. von Fricken[1], Rui-Ruo Jiang[2], Barbara Qurollo[3], Bazartseren Boldbaatar[4], Ya-Wei Wang[2], Sukhbaatar Lkhagvatseren[4], Jeffery W. Koehler[5], Thomas C. Moore[6], Pagbajab Nymadawa[7], Benjamin D. Anderson[6], Graham Matulis[8], Jia-Fu Jiang[2], Gregory C. Gray[6]

[1]Department of Global and Community Health, George Mason University, Fairfax, VA, United States, [2]State Key Laboratory of Pathogen and Biosecurity, Beijing Institute of Microbiology and Epidemiology, Beijing, China, [3]Department of Clinical Sciences, College of Veterinary Medicine, North Carolina State University, Raleigh, NC, United States, [4]Institute of Veterinary Medicine, Ulaanbaatar, Mongolia, [5]United States Army Medical Research Institute of Infectious Diseases (USAMRIID), Frederick, MD, United States, [6]Division of Infectious Disease, Duke Global Health Institute, Duke University, Durham, NC, United States, [7]Mongolian Academy of Medical Sciences, Ulaanbaatar, Mongolia, [8]George Mason University, Fairfax, VA, United States

Ehrlichia and *Anaplasma* are tick-borne bacterial diseases that cause human granulocytic anaplasmosis (HGA) and human monocytic ehrlichiosis (HME). Additionally, these pathogens are responsible for severe illness in animals, potentially having a major impact on economies which rely heavily on livestock, such as in Mongolia. Previous studies of tick-borne diseases (TBDs) in East and Central Asia have focused on areas in China and Russia, leaving the status of TBDs in Mongolia largely undescribed. In this study, ticks were collected, identified, and pooled from three distinct environments across central Mongolia. Tick pools were homogenized for polymerase chain reaction (PCR) analysis of relevant TBD genes. This study focused on sequencing *Anaplasma* sp. gene targets *gltA, msp2,* and 16S rRNA, as well as *Ehrlichia* sp. 16S rRNA and *sodB* genes. *A. phagocytophilum* had a calculated 1.6% (95% CI 0.5-3.7%) maximum likelihood estimation (MLE) infection rate in *I. persulcatus* ticks collected from the Selenge aimag (province). The calculated MLE infection rate of *A. ovis* in *D. nuttalli* ticks ranged from 4.82% (05% CI 2.4-7.7%) in the Dornogovi aimag to 15.2% (95% CI 9.7-22.8%) in the Selenge aimag. Non-specific *Anaplasma* and *Ehrlichia muris* both had MLE rates of 1.2% (95% CI 0.3-3.1%) in *I. persulcatus* ticks from Selenge. A majority of *D. nuttalli* ticks were recovered from livestock and 51% of those pools carried *A. ovis*. Genetic analyses of selected 16S and *gltA* positive amplicons confirmed the PCR results with phylogenetic clustering, indicating genetic relatedness to other species found in China and Asia. Considering the collective economic losses that can result from these pathogens and the potential for spillover to nomadic herdsmen, these results highlight the need for better TBD surveillance and intervention within Mongolia.

1546

BACTERIAL GENERA IN SALIVARY GLANDS AND GUT TISSUE OF *RHIPICEPHALUS MICROPLUS* TICKS FROM LIVESTOCK IN ANTIOQUIA, COLOMBIA

Juan A. Segura

Universidad Pontificia Bolivariana, Medellín, Colombia

Since ticks (Ixodida) are obligated blood-feeders have become an increasing problem to people and animals in the world. They are considered to be of medical and veterinary importance because can also transmit many human and animal disease pathogens, which include viruses, protozoa and bacteria. *Rhipicephalus microplus* is important tick specie that economically affects the livestock industry in tropical and subtropical regions of the world, despite its importance, its role like biological vector have been few researched so far. In this study, bacterial

diversity of *salivary glands* and gut tissue of *R. microplus ticks* was characterized by massive parallel sequencing of 16S amplicons. For this, *R. microplus ticks were collected in cattle in two regions from Antioquia, Colombia.* Salivary glands and gut tissue were independently pooled according to the geographic collection sites in five female ticks per pool. *DNA was extracted using PureLink® Genomic DNA Mini Kit and the variable region* V3-V4 of 16S rRNA was amplified using universal primers. Amplicons were sequenced using the MiSeq platform (Illumina) and bacterial diversity analysis were performed with Mothur v1.39 following an OTU-based approach. Sequences were clustered into OTUs with a 97% identity and classified using the Ribosomal Database Project database v9. A total of 5600 OTUs including rare OTUs were detected in salivary glands and gut tissues from *R. microplus.* The number of OTUs per sample ranged from 288 to 1250. Some OTUs identified were classified into the following bacterial genera: *Pantoea, Lactobacillus*, *Gardnerella, Stenotrophomonas, Sphingobacterium, Prevotella, Enterobacter, Pseudomonas, Anaplasma, Coxiella* and *Ehrlichia.* Our results provide an important molecular approach to describe bacterial organisms associated to *R. microplus* from Livestock in Antioquia, Colombia. In addition, pathogenic genera detected may be useful for implement entomological and epidemiological surveillance programs.

1547

TICK-PATHOGEN INTERACTION: CONNECTING THE DOTS BETWEEN INNATE IMMUNITY AND REDOX SIGNALING PATHWAYS

Faizan Tahir, Shahid Karim

University of Southern Mississippi, Hattiesburg, MS, United States

Dietary selenium, through its incorporation into selenoprotein, plays an important role in immunity and inflammation responses due to its crucial roles in regulating reactive oxygen species and redox status in almost all tissues. In previous studies, it has been shown that selenophosphate synthetase 2 (SPS2), a homologue of selenophosphate synthetase (SelD) identified in mammals, is essential for selenoprotein biosynthesis. Relish, a homologue of nuclear factor-kappa B (NF-kB), in the immune deficiency signaling pathway, regulates the expression of microplusin, an antimicrobial peptide (AMP). In this study, we hypothesize that silencing of SPS2 and Relish will cause an increase in *Rickettsia parkeri* level in infected *A. maculatum* ticks. To define the functional role of SPS2 and Relish in hematophagy and pathobiome colonization, an RNAi approach was utilized to deplete target genes expression in pathogen infected ticks. The transcriptional expression of target genes was confirmed in the knockdown tissues of both SPS2 and Relish. A significant decrease in replete weight, and a marked increase in distress in the host provided evidence for the critical role of target genes during feeding of knocked down ticks. A qPCR and 16s rRNA diversity assays showed that the gene-silenced ticks had significant increase in *R. parkeri* load than the control, proving that SPS2 and Relish play a role in the maintenance of tick pathobiome. Interplay between redox signaling and innate immunity pathways will be discussed in the context of tick-pathogen interactions.

CANINE SENTINELS OF VECTOR-BORNE DISEASE IN TEXAS, USA: HIGH-RISK DOGS INFECTED WITH DIVERSE AGENTS INCLUDING *TRYPANOSOMA CRUZI*, BUT LITTLE EVIDENCE OF *BORRELIA BURGDORFERI*

Carolyn L. Hodo[1], Jessica Y. Rodriguez[2], Rachel Curtis-Robles[1], Italo B. Zecca[1], Lisa D. Auckland[1], Karen F. Snowden[1], Kevin J. Cummings[3], Sarah A. Hamer[1]

[1]Texas A&M University, College Station, TX, United States, [2]Zoetis, Parsippany, NJ, United States, [3]Cornell University, Ithaca, NY, United States

Dogs are useful as sentinels for human risk of exposure to vector-borne diseases. In the southern US, while screening is routine for many vector-borne diseases in dogs, exposure to *Trypanosoma cruzi*, agent of Chagas disease, is under-recognized. *T. cruzi* causes fatal heart disease in dogs across the southern US, but autochthonous infection with *T. cruzi* in humans is less common. Additionally, as tick-borne diseases continue to emerge across the US, understanding of the tick and pathogen communities in the southern US remains incomplete. We conducted a repeated cross-sectional study to determine the prevalence of *T. cruzi*; the tick-borne pathogens *Ehrlichia* spp., *Anaplasma* spp., and *Borrelia burgdorferi*; and the mosquito-borne filarial nematode *Dirofilaria immitis* among dogs recently admitted to animal shelters across Texas. These dogs may be considered at high risk for vector-borne exposures due to prolonged time spent outdoors and lack of routine ectoparasite treatment. We also collected ticks from these dogs and tested them for infection with *Rickettsia* spp. and *Borrelia* spp. Among 608 dogs sampled, 110 (18.1%) were seropositive for T. cruzi. Prevalence estimates of the other four vector-borne agents were as follows: *Ehrlichia* spp. 3.6% (22/608); *Anaplasma* spp. 6.9% (42/608); *B. burgdorferi* 0.2% (1/608); and *D. immitis* 16.0% (97/608), with regional variation in exposure. We documented coinfections or coexposures in 41 dogs, but only coexposure to *Ehrlichia* spp. and *Anaplasma* spp. was more frequent than expected ($P<0.001$). We collected 353 ticks from dogs, mostly *Rhipicephalus sanguineus* with few *Ixodes scapularis* and *Dermacentor variabilis*. Three percent of *R. sanguineus* were infected with a *Rickettsia* endosymbiont, and no *I. scapularis* harbored *Borrelia* spp. This study reports exposure to diverse vector-borne pathogens among Texas shelter dogs, including widespread exposure to *T. cruzi* at a prevalence that is comparable to *D. immitis*. Only one dog was seropositive for *B. burgdorferi*, suggesting very low risk of exposure across the state. These data can be used to direct future investigations and prioritize public health campaigns.

1549

THE DILEMMA OF RECENT DISCOVERY, DETECTION AND DIVERSITY OF NEW RICKETTSIAE AND RICKETTSIAL DISEASES

Allen L. Richards

Naval Medical Research Center, Silver Spring, MD, United States

Rickettsial diseases are associated with well-known pathogens such as *Rickettsia rickettsii* (Rocky Mountain spotted fever), *Anaplasma phagocytophilum* (human granulocytic anaplasmosis), *Ehrlichia chaffeensis* (human monocytic ehrlichiosis), and *Orientia tsutsugamushi* (scrub typhus) and continue to be a disease, social and economic burden to society. This problem is compounded by the recent discoveries of new rickettsial agents within the known arthropod vectors of lice, mites, ticks and fleas, as well as detecting these agents within new invertebrate hosts such as mosquitoes, tsetse flies and leaches. The discovery of new agents causing new diseases is bad enough, but finding new agents for old diseases in new endemic regions (e.g. scrub typhus) is increasing the public health risk of rickettsial diseases in a fashion not previously envisioned.

1550

SPECIFICITY ASSESSMENT OF REAL TIME PCR PROTOCOLS FOR THE DETECTION OF *RICKETTSIA FELIS* AND *R. ASEMBONENSIS* USING RICKETTSIAE STRAINS FROM COSTA RICA

Guillermo Barquero-Ureña[1], Dione E. Palma-Carranza[1], Rolando D. Moreira-Soto[1], Catherine Santanello[2], Luis M. Romero-Vega[1], Adriana Troyo[1]

[1]Universidad de Costa Rica, San José, Costa Rica, [2]Southern Illinois University Edwardsville, Edwardsville, IL, United States

Rickettsia felis is an emergent pathogen that causes a disease known as "flea-borne spotted fever". Even though *Ctenocephalides felis* fleas are considered the main vectors and reservoirs of *R. felis*, they can also harbor similar rickettsiae that may be considered endosymbionts or

microorganisms of unknown pathogenicity; one of them is *Rickettsia asembonensis*. Some of the described rickettsiae species that have been reported in Costa Rica include *Rickettsia rickettsii*, *Rickettsia amblyommatis*, *Rickettsia bellii*, *R. felis*, and *R. asembonensis*. The purpose of this study was to assess the specificity of two real time PCR protocols that are available for the detection of *R. felis* and *R. asembonensis*, using different rickettsiae isolated in Costa Rica as well as rickettsiae from local fleas. Both real time PCR protocols were tested (presence/absence) using DNA from local cell culture isolates of *R. rickettsii, R. amblyommatis*, and *R. felis*, as well as DNA from flea samples positive for *R. asembonensis* (*Rickettsia* sp. strain RF2125). In addition, fleas from 3 sites in Costa Rica, where *R. felis* and *R. asembonensis* have been previously detected (Tres Ríos, Desamparados, Guápiles), were collected from dogs and tested using both protocols. The real time PCR for *R. felis* and *R. asembonensis* were specific, as they detected the presence of these species, and not other rickettsiae; there were no cross reactions between *R. felis* and *R. asembonensis*. *Rickettsia felis* was detected in 7 of 16 fleas from Tres Ríos, 8 of 17 from Desamparados, and 1 of 12 from Guápiles, although some of the positive fleas seem to have low infections. Preliminary results showed that *R. asembonensis* was also detected in fleas from all sites, although more tests are currently being conducted. These results show that the protocols tested can be used to specifically detect *R. felis* and *R. asembonensis* in fleas from Costa Rica; in addition, they will be useful for determining the possible co-infection of fleas with these rickettsiae, and for evaluating interactions such as competition for niche phenomena.

THE IMPACT OF SCABIES ON THE HEALTHY HUMAN SKIN MICROBIOTA

Katja Fischer[1], Charlotte Bernigaud[1], Martha Zakrzewski[1], Martha Zakrzewski[1], Pearl M. Swe[1], Anthony T. Papenfuss[2], Ehtesham Mofiz[2], Françoise Botterel[3], M.G. Karmarkar[4], Deborah Holt[5], Bart Currie[6], Olivier Chosidow[7]

[1]QIMR Berghofer Medical Research Institute, Herston, Australia, [2]The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, [3]Universite´ Paris-Est (UPE), Paris, France, [4]Seth G.S Medical College & K.E.M Hospital, Mumbai, India, [5]Menzies School of Health Research, Darwin, Australia, [6]Department of Infectious Diseases, Royal Darwin Hospital, Darwin, Australia, [7]Hôpital Henri-Mondor, Parasitology and Mycology, Department of Microbiology, DHU VIC, UPEC, Paris, France

We hypothesize that in the tropics, scabies mite infection plays a significant role in the establishment, proliferation and transmission of opportunistic, pathogenic bacteria and forms a critical precursor of skin-borne infection that can lead to severe illness. The first *in vivo* evidence confirming a scabies-associated microbiome came from a longitudinal pilot study in a scabies porcine model. We demonstrated a substantial impact of mite infection on healthy skin microbiota, causing a shift from commensal to pathogenic staphylococci. To investigate scabies infestations in humans we analysed metagenome data generated from DNA preparations of mite and skin material collected from severe crusted scabies patients located in northern Australia. A remarkable preliminary finding is the high abundance of opportunistic pathogens, including *Staphylococcus argenteus* and *Acinetobacter baumanii*. As the prevalence of these pathogens continues to increase, confirming a precursor role of scabies in these skin and soft tissue infections is adamant. To define the microbiome in skin lesions of patients with common scabies in different geographical locations (remote North Queensland, India and France) we analyse skin scrapings from multiple body sites including control samples from corresponding co- and contra-lateral healthy sites using 16S and ITS1 rRNA amplicon Illumina MiSeq sequencing. The study will provide a more global picture of the microbes associated with scabies. To understand the mite internal microbiome, analysing the metagenome data of washed mites revealed microbial genera reported previously to be symbionts in various arthropods. Among the potential endosymbionts detected, Streptomyces species supply nutrients and antibiotics to support their arthropod hosts, and some species cause chronic subcutaneous infection in humans. To elucidate the role of Streptomyces in scabies we confirmed its presence in situ by FISH analysis, and quantified its abundance in individual parasite stages by species specific ddPCR. Targeting bacterial symbionts could be an alternative approach to scabies control.

1552

AGENT-BASED MODELLING OF TICK-BORNE DISEASE EXPOSURE IN MONGOLIAN LIVESTOCK AND HERDERS

Alexis Garretson, Michael E. von Fricken

Department of Global and Community Health, George Mason University, Fairfax, VA, United States

Investigating the risk factors associated with tick-borne disease exposure can have significant impacts on global health outcomes - particularly in resource-poor regions. Mongolian herders are at an increased risk of contracting tick-borne diseases because of the close interaction with livestock and landscape features, and provide an illustrative case for testing predictive models. To evaluate the effectiveness of an agent-based model (ABM) of tick-borne disease developed to predict and identify at-risk populations, a general ABM of tick-borne disease transmission was developed and parameterized for Mongolian herders. The model was used to predict seropositivity of herders and livestock in and compared to data collected in 2014 to evaluate model success and fit. Compared to the collected data, the preliminary ABM results suggest that the prevalence may be underestimated using this method, in comparison to differential equation models which may overestimate the prevalence. Utilizing ABM and differential models in tandem may best approximate the collected levels of infection and seroprevalence in at-risk populations. Due to limited diagnostic capabilities at both the local and national level, an increased understanding of the risk for infection with these high consequence pathogens can lead to improved prevention methods and decreased morbidity and mortality.

1553

EFFICACY AND RESIDUALITY OF LARVICIDE IN SIMULATED FIELD CONDITIONS: COMPARATIVE EVALUATION OF TWO PRODUCTS OF PIRIPROXIFEN AT 0.5% G BEFORE *AEDES AEGYPTI*

Miriam G. Palomino Salcedo[1], Jesus A. Pinto Caballero[1], Pamela K. Yañez Vallejo[2], Henry A. Bonilla Bruno[1]

[1]Instituto Nacional de Salud, Lima, Peru, [2]Pamela, Lima, Peru

In the year 2017, dengue presented an increase of cases, reporting 82 thousand cases. Being, the main strategy of vector control the chemical control. The present study compares the efficacy and residuality in simulated field conditions of two piriproxifen products: PYRILARV® 0.5% G and SUMILARV® 0.5 G, which were evaluated at a concentration of 0.01 mg / L (WHO). Third stage larvae of Ae. aegypti, susceptible strain Rockefeller. Both products were tested simultaneously with 4 treatments: without water exchange and with three water exchanges at 25, 50 and 75% in a total volume of 1 liter. Each treatment was evaluated with five repetitions. In the controls, 4 replicas were used. The effectiveness and residuality of both products was determined through bioassays with 25 larvae in each replication at 1, 30 and 60 days post-treatment, being evaluated until the emergence or death of all the mosquitoes and the percentage of adult emergence inhibition was determined (IE%, WHO 2005). The generic formula PYRILARV® 0.5% G, caused 100% of the IE at 1 day post-treatment); however, its effect decreased abruptly from 100 to 53.2% at 30 days and decreased to <1 to 60 days. On the other hand, SUMILARV®, caused percentages of IE> 97 up to 60 days. The results according to the water exchanges at 25, 50 and 75% show that PIRILARV® 0.5% G presents differences in IE%, where a higher percentage of water exchange generates less IE%, this effect was observed at 30 days and in SUMILARV® 0.5 a proportional decrease in IE% was observed as more volumes of water were exchanged for 60 days. In addition, it was observed that both products generate higher mortality

in pupae (91%). Physical-chemical analysis shows that the analyzed sample of PYRILARV® 0.5% G, lot n° 55120 shows a high variability (DSR> 2%) in the content of pyriproxyfen. In the country, there is a high risk of the increase in viral diseases transmitted by Ae. aegypti, by the use of insecticides of low quality and demonstrated inefficiency in the reduction of mosquito populations by a "limited vector control intervention."

1554

EFFECTS OF AERIAL ADULTICIDE SPRAYING ON THE RELATIVE ABUNDANCE OF *CULEX TARSALIS* AND *CX. PIPIENS*

Karen M. Holcomb[1], Robert C. Reiner[2], Christopher M. Barker[1]

[1]University of California-Davis, Davis, CA, United States, [2]University of Washington, Seattle, WA, United States

In order to minimize transmission of West Nile virus to humans, mosquito control districts utilize a variety of methods to reduce the abundance of adult and larval mosquitoes. Of the available control options, aerial adulticides are among the most effective tools for immediate reduction of infectious adult mosquito populations during periods of epidemic risk. However, estimates on the magnitude and duration of reductions from aerial adulticides vary spatially and temporally due factors associated with stochastic variation in nightly trapping success like weather and seasonality. Thus, making it difficult to estimate the effects of single applications. We used a decade (2006-2015) of trap collection data from CO_2-baited traps in Sacramento and Yolo counties, California to fit generalized additive models that adjusted for expected spatial and temporal trends in adult female abundance for *Culex tarsalis* and *Cx. pipiens*, the primary West Nile virus vectors in California. Estimates for the magnitude and duration of reductions in relative abundance for each species in urban and agricultural areas were obtained from the models. One-week post-spraying, aerial sprays reduced *Cx. pipiens* by an estimated mean of 78.6% (95% CI: 70.3-84.6) and in urban areas and 90.6% (95% CI: 72.0-96.9) in agricultural areas. *Cx. tarsalis* populations were reduced by a mean of 61.3% (95% CI: 47.1-71.7) in urban areas and 79.7% (95% CI: 51.3-91.5) in agricultural areas. Reductions persisted for both species, with longer population suppression for *Cx. pipiens* compared to *Cx. tarsalis*. Taken together, our results indicate that aerial adulticides are effective for rapid and sustained reductions of West Nile virus vectors, which is critical for preventing outbreaks of disease.

1555

IMPACT OF VOLATILE METOFLUTHRIN ON *ANOPHELES DARLINGI* BEHAVIOR EVALUATED IN EXPERIMENTAL HUTS IN ZUNGAROCOCHA, LORETO, PERÚ

Fanny Castro-Llanos[1], Victor Lopez-Sifuentes[1], Craig A. Stoops[1], Michael L. Fisher[1], Scott A. Ritchie[2], Gissella M. Vásquez[1], Gregor J. Devine[3]

[1]U.S. Naval Medical Research Unit No. 6, Bellavista, Peru, [2]James Cook University (JCU), Queensland, Australia, [3]Mosquito Control Laboratory, Queensland Institute of Medical Research (QIMR), Berghofer Medical Research Institute, Queensland, Australia

New formulations of volatile pyrethroids have behavioral and lethal impacts on mosquito vectors, suggesting a great potential as an alternative mosquito control tool. In this study, we evaluated the effects of metofluthrin emanators (SumiOne™ net) on *Anopheles darlingi* in experimental huts in Loreto, Peru. Two trials were performed, one in closed huts and another one in huts with opened window interception traps. Wild-caught *An. darlingi* females were collected 1d before release in experimental huts (100 females per hut); releases were performed at 1800 for a 5-day period per trial. In the first trial, we evaluated the effects of 1 and 2 emanators on protected human landing counts (HLC; mosquitoes landing on collector's exposed right leg) and mosquito knock down (KD). HLC were performed 10 min before (pre-treatment), and 55 and 105 min after (post-treatment) emanator deployment. In the second trial, we compared an untreated control vs. a 2-emanator treatment. Emanators were deployed at 1800 h; HLC and mosquito KD were recorded at 10, 5 and 120 min after deployment (post-treatment). Window interception traps were checked hourly from 2100 to 0100 h. All trials consisted of 10 reps/treatment; treatment means were compared using Kruskal-Wallis Test. In closed huts, HLC decreased considerably post-treatment relative to pre-treatment with both 1 (2.7±1.7 vs. 0.3±0.4; $p<0.005$) and 2 (1.7±1.2 vs. 0.2±0.4; $p<0.005$) emanators; KD increased with 1 (0.3±0.5 vs 4.2±2.4) and 2 (1.1±6.0 vs. 10.3±6.0; $p<0.005$) emanators. In semi-enclosed huts, HLC in untreated control was 18 times higher than that in the 2-emanator treatment (1.8±1.0 vs. 0.1±0.3; $p<0.005$); KD with was 5 times higher than that of untreated control (4.8±3 vs. 0.9±1.5; $p<0.005$). The number of mosquitoes exiting the hut did not differ between the 2-emanator treatment and control (12±5 vs. 16±6; $p>0.005$). The metofluthrin formulation evaluated had an impact on *An. darlingi* behavior having recorded reduced biting and knock down in experimental huts, supporting potential implementation as a mosquito control method in real, endemic settings.

1556

FIELD TESTING INSECTICIDE-TREATED BARRIER SCREENS FOR PROTECTION FROM HOST-SEEKING, EXOPHILIC MOSQUITOES IN THE NORTHERN PERUVIAN AMAZON

Victor M. Lopez-Sifuentes, Karin S. Escobedo-Vargas, Hugo Jaba, Michael L. Fisher, Craig A. Stoops, Gissella M. Vasquez

U.S. Naval Medical Research Unit No. 6, Bellavista, Peru

Insecticide barriers are an important component of mosquito control programs. Moreover, recent studies have shown that insecticide-treated mesh barriers can reduce foraging mosquito densities, suggesting their potential use as a new mosquito control tool. This study evaluated whether untreated and insecticide-treated screens used as vertical barriers can intercept and reduce densities of host-seeking and resting exophilic mosquitoes in rural areas in the periphery of Iquitos, Loreto, Peru. Mosquito species composition, densities, and human biting rates (HBR) were recorded via protected Human Landing Count (HLC) and direct collection from screens. We first tested two untreated barrier screens (10 m x 2 m) placed 10 m away from a hut in Zungarococha community (March 2-7, 2017). A second trial was performed using an untreated screen and a permethrin-treated screen (10 m x 2 m) placed 10 m away from a dining hall in a military base in Mapacocha (September 5-14, 2017). A total of 3,010 mosquitoes (1,850 by HLC; 1,160 from screens) that comprised 29 species were collected from Zungarococha. *Anopheles darlingi* (40%) and *Culex quinquefasciatus* (18%) were the most abundant species. Baseline HBR (no screen) averaged 20.1 and 32.7 mosquito bites/man/hour intra- and peri-domestic, respectively; untreated screen HBR were 14.4 and 23.1 mosquito bites/man/hour intra- and peri-domestic, respectively (28-29% HBR reduction). In Mapachocha, a total of 2,422 mosquitoes (1,210 by HLC; 681 from untreated screen; 531 from treated screen) that comprised 16 species were collected. *Culex quinquefasciatus* (82%) and *Mansonia indubitans/titillans* (8%) were the most abundant. Baseline HBR (no screen) averaged 8.1 and 12.0 mosquito bites/man/hour intra- and peri-domestic, respectively; treated screen HBR were 5.9 and 8.2 mosquito bites/man/hour intra- and peri-domestic, respectively (27-32% HBR reduction). Results suggest that barrier screens can effectively trap multiple species of foraging, exophilic mosquitoes and potentially reduce exposure to infective mosquito bites in the Amazon.

1557

TOXIC, ANTIFEEDANT, AND REPELLENT ACTIVITY OF DRIMANE SESQUITERPENES FROM THE MEDICINAL PLANT *CINNAMOSMA FRAGRANS* AGAINST *AEDES AEGYPTI* MOSQUITOES

Edna A. Inocente[1], H. Liva Rakotondraibe[2], Peter M. Piermarini[1]

[1]The Ohio State University, Wooster, OH, United States, [2]The Ohio State University, Columbus, OH, United States

Chemical pesticides are often used to control populations of mosquito vectors. However, overuse of these chemicals can lead to resistance in mosquitoes. Moreover, several environmental and health concerns such as accumulation of harmful residues in the environment, and undesirable effects on non-target organisms, including beneficial insects and vertebrates, have been proven to be associated with repeated use of conventional chemical pesticides (e.g., pyrethroids, DDT). These problems highlight the need for discovering safe insecticides and repellents. Recently, compounds derived from botanical sources have received much attention as potentially environmentally-safe bioactive compounds against pestiferous insects. Notably, drimane sesquiterpenes, a class of plant secondary metabolites, are known to elicit antifeedant and toxic effects in insect pests. However, the activities of these compounds against mosquitoes have not been previously characterized. Here we demonstrate that the bark of a plant (*Cinnamosma fragrans*), commonly used in Madagascar as a traditional remedy for a variety of human illnesses, is enriched with an electrophilic drimane sesquiterpene dialdehyde (cinnamodial) that is toxic, antifeedant, and repellent to the yellow fever mosquito *Aedes aegypti,* an important vector of emerging arboviral diseases in humans, such as chikungunya, dengue, and Zika fevers. In addition, we identify other drimane sesquiterpenes from the bark of *C. fragrans* that exhibit toxic and/or antifeedant/repellent activity against *Ae. aegypti* suggesting that the bark contains a 'cocktail' of compounds that are bioactive against mosquitoes. Our data indicate that drimane sesquiterpenes may serve as a valuable chemical platform for the development of next-generation, natural product-based insecticides and repellents for controlling mosquito vectors of emerging arboviruses.

1558

CO-OCURRENCE OF THE V1,016I AND F1,534C MUTATIONS IN *AEDES AEGYPTI* POPULATIONS RESISTANT TO PYRETHROIDS AND DDT FROM THE COLOMBIAN CARIBBEAN REGION

Ronald Maestre-Serrano[1], Paula Pareja-Loaiza[2], Doris Gómez-Camargo[2], Gustavo Ponce-García[3], Adriana E. Flores[3]

[1]Universidad Libre, Barranquilla, Colombia, [2]Universidad de Cartagena, Cartagena, Colombia, [3]Universidad Autónoma de Nuevo León, San Nicolás de los Garza, NL, Mexico

Knock-down resistance is conferred mainly by non-synonymous mutations, that reduce the binding between the pyrethroid insecticides and the voltage-gated sodium channel. In 2014, it was reported for first time in *Aedes aegypti* from Colombia the V1,016I mutation and in 2016 the F1,534C mutation in populations resistant to DDT and pyrethroid insecticides. The present study was carried out to determine the frequency and co-occurrence of both mutations in the voltage-gated sodium channel in populations of *Ae. aegypti* and their role in the resistance of pyrethroids and DDT. Nine populations of *Ae. aegypti*, previously characterized as resistant to the insecticides λ-cyhalothrin, deltamethrin, cyfluthrin, permethrin and DDT were used for this study. Genomic DNA was used to determine genotypes by allele-specific PCR for V1,016I and F1,534C mutations. All populations analyzed presented both mutations, with allelic frequencies between 0.07-0.35 for I1,016 and 0.47-0.88 for C1,534. We identified a percentage of co-occurrence of mutant homozygotes I1,016/C1,534 of 5.3%. A significant correlation was found between the knockdown resistance values ($RRCK_{50}$) and the frequency of double homozygous mutants (I1,016/C1,534) for deltamethrin ($r = 0.69$, $P < 0.05$) and cyfluthrin ($r = 0.83$, $P < 0.05$); the frequency of homozygous mutants and heterozygotes (I1,016/F1,534C) for λ-cyhalothrin ($r = 0.91$, $P < 0.05$) and permethrin ($r = 0.70$, $P < 0.05$); heterozygous and homozygous mutants (V1,016I/C1,534) for cyfluthrin ($r = 0.82$, $P < 0.05$) and DDT ($r = 0.76$, $P < 0.05$). In conclusion, the presence of dual kdr mutations in the populations of *Ae. aegypti* from the Colombian Caribbean Region demonstrate a major role in the resistance to pyrethroids and DDT.

1559

PARALLEL EVOLUTION OF *VGSC* MUTATIONS AT DOMAINS IS6, IIS6 AND IIIS6 IN PYRETHROID RESISTANT *AEDES AEGYPTI* FROM MEXICO

Karla L. Saavedra-Rodriguez[1], Farah Vera Maloof[1], Corey L Campbell[1], Julian Garcia-Rejon[2], Audrey Lenhart[3], Patricia Penilla[4], Americo Rodriguez[4], Arturo Acero[4], Adriana E Flores[5], Gustavo Ponce[5], Saul Lozano[1], William C Black IV[1]

[1]Colorado State University, Fort Collins, CO, United States, [2]Centro de Investigaciones Regionales Dr. Hideyo Noguchi, Universidad Autónoma de Yucatán, Merida, Mexico, [3]Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Centro Regional de Investigacion en Salud Publica, Instituto Nacional de Salud Publica, Tapachula, Mexico, [5]Facultad de Ciencias Biologicas, Universidad Autonoma de Nuevo Leon, San Nicolas de los Garza, Mexico

Presence of pyrethroid resistance in *Aedes aegypti* mosquito populations threatens our ability to control transmission of dengue, Zika and chikungunya viruses in Mexico. A major mechanism of pyrethroid resistance, commonly known as knockdown resistance (kdr) is conferred by amino acid replacements in the voltage gated sodium channel (*vgsc*). Around 11 replacements have been associated with pyrethroid resistance. Interestingly, replacements can vary across geographies and specific combinations of replacements synergize resistance. In Mexico, two kdr replacements (F1,534C and V1,016I) have co-evolved in the last 16 years, eventually reaching fixation across many *Ae. aegypti* populations. Recently, V410L in DI6 segment of *vgsc* was identified in a pyrethroid resistant *Ae. aegypti* strain from Brazil and its effect on *vgsc* activity was confirmed by electrophysiology; nevertheless, V410L was not detected in wild *Ae. aegypti* collections from Brazil. A genome association mapping study in our laboratory identified V410L in *Ae. aegypti* from Mexico and we developed a genotyping system to screen individuals from 25 *Ae. aegypti* historical collections conducted from 2000 to 2016. We tracked the first V410L heterozygote back to 2002. Allele frequencies increased during the last 16 years in close linkage disequilibrium with V1,016I and F1,534C. We also tested the phenotype/genotype association at the tri-locus genotype level showing that the triple resistant homozygote genotype is associated with resistance to both permethrin and deltamethrin.

1560

EFFICIENT ALLELIC DRIVE DEMONSTRATED IN *DROSOPHILA* WITH POSSIBLE APPLICATIONS IN INSECTICIDE RESISTANCE ERADICATION

Raja Babu Singh Kushwah[1], Annabel Guichard[2], Tisha Haque[2], Marketta Bobik[2], Xiang-Ru S. Ru[2], Valentino Gantz[2], Ethan Bier[2]

[1]Tata Institute for Genetics & Society, Bangalore, India, [2]University of California San Diego, San Diego, CA, United States

Insecticide resistance is a global problem in a wide range of insect pest species. Various mutations are known to confer DDT/pyrethroid resistance in many insect/pest species including mosquitoes. We want to develop an allelic drive to eliminate such resistance in field population of *Anopheles stephensi*. We have already demonstrated an efficient allelic drive making use of the Notch locus, in which dominant gain-of function and loss-of-function are available. We use a strategy involving a DsRed-tagged genetic insertion that encodes two guide RNAs: the first gRNA ensures the self propagation this insertion, and the second gRNA directs the Cas9

dependent cleavage of a Notch sensitive allele. Another more general approach (copy-grafting) permitting selective inheritance of a desired allele some distance from the gRNA cut site is also developed. We have also observed a phenomenon we refer to as shadow-drive wherein perdurance of non-genetically encoded Cas9/gRNA complexes results in gene-drive associated with lethal somatic mosaicism in the next generation. The combination of efficient allelic-drive and trans-generational lethal mosaic shadow-drive has significant implications for a wide variety of applications and greatly broadens the potential applications of active genetics. In future we will use this strategy to resensitize the resistant field populations of many vectors responsible for various insect-borne diseases. Regarding this we are going to use the model organism *Drosophila melanogaster* to study the polymorphism at two important knockdown resistance (*kdr*) locus i.e. M918 and L1014 in the voltage gated sodium ion channel globally known in *Anophelines spp.*

1561

INGESTED INSECTICIDE TO CONTROL *AEDES AEGYPTI*: DEVELOPING A NOVEL DRY ATTRACTIVE BAIT STATION (DABS) FOR INTRA-DOMICILIARY USE

Galo Rivera[1], David A. Larsen[2], Anna M. Stewart-Ibarra[3], Robert S. Hikida[4], María de los Ángeles López[5], Alex Aguirre[6], Bianca Morejón[6], **Marco Neira**[6]

[1]Vector Biology Group, The Max Planck Institute for Infection Biology, Berlin, Germany, [2]Syracuse University, Syracuse, NY, United States, [3]Department of Medicine and Center for Global Health and Translational Science. State University of New York Upstate Medical University, Syracuse, NY, United States, [4]Ohio University, Athens, OH, United States, [5]Universidad de las Américas – UDLA, Quito, Ecuador, [6]Center for Research on Health in Latin America (CISeAL), Pontificia Universidad Católica del Ecuador, Quito, Ecuador

Attractive toxic sugar baits are a promising mosquito control strategy; however, no studies have yet examined how they might be adapted to control *Aedes aegypti*, the main vector of arbovirosis such as dengue, chikungunya and Zika. This study reports on laboratory results of a novel dried attractive bait station (DABS) to control *Ae. aegypti*. DABS were manufactured using foam pieces previously soaked in a sucrose solution laced with boric acid, and allowed to air-dry. To establish the effectiveness of our DABS for killing *Ae. aegypti*, laboratory-reared mosquitoes were introduced into cages with or without a DABS, and mortality was measured. To determine whether the toxic effect was caused by ingestion of the dry bait, we performed "disrupted-feeding" tests in which specimens in experimental groups had their proboscis surgically removed, while control specimens were unaltered. Both experimental and control specimens were exposed to DABS, and mortality was measured. We used electron microscopy to identify any potential damage to midgut tissue caused by ingestion of the toxic bait. Additionally, we tested the persistence of the DABS toxicity for up to 120 days post-manufacturing. Mortality post-exposure to DABS reached 55% within 24 hours, and 100% within 72 hours. Mortality was observed in both starved and blood-fed *Ae. aegypti* females. Furthermore, our results suggest the toxic bait enters the insect´s organism by ingestion, and electron microscopy revealed potential tissue damage in the midgut of specimens exposed to DABS. The killing effect of the devices was maintained for up to 120 days after manufacturing. These results suggest that DABS are effective at killing *Ae. aegypti* in laboratory settings, and prompt the need for further testing these devices under field conditions. DABS can be constructed cheaply, and require no electricity to function. Therefore, if deemed effective under field conditions, the production of these devices may be easily scaled for use in resource-limited settings, potentially becoming a novel and affordable tool for *Ae. aegypti* control.

SELECTION FOR PERMETHRIN RESISTANCE IN *AEDES ALBOPICTUS* FROM CHIAPAS, MEXICO

Ashley J. Janich[1], Karla L. Saavedra-Rodriguez[1], Farah Z. Vera-Maloof[1], Americo D. Rodriguez-Ramirez[2], Patricia Penilla-Navarro[2], Alma D. Lopez-Solis[2], Francisco Solis-Santoyo[2], William C. Black[1]

[1]Colorado State University, Fort Collins, CO, United States, [2]Centro Regional de Investigación en Salud Pública, Tapachula, Mexico

Insecticide resistance and its known mechanisms have been extensively studied in *Aedes aegypti* mosquitoes, the major vectors of Zika, Dengue and Chikungunya viruses. However, another important vector is *Aedes albopictus.* The primary method to control the spread of these vectors and their diseases is by insecticide application. With continued application of insecticides like permethrin, *Ae. aegypti* has developed an observable resistance, requiring increasingly higher concentrations to be killed. Since permethrin is widely used in many countries, it is important to understand if *Ae. albopictus* is also developing resistance and what possible mechanisms are involved. We collected *Ae. albopictus* from Tapachula, Chiapas, MX, and reared them in our lab. We exposed adults from each location to several concentrations of permethrin. The concentration needed to kill 50% of the mosquitoes (LC_{50}) and resistance ratios (RR) were compared to our control colony from New Jersey. Survivors were bred to generate the "La Macha" colony, which were later exposed to the same concentrations in the previous assays. Survivors were kept and bred again. We will continue these procedures for several generations. Another portion of La Macha will be reared separately and remain unexposed to insecticides for later comparison. We observed lower mortality in mosquitoes from Mexico compared to the control, with RR ranging from 1.27 to 2.06, indicating there is a low level of resistance. We predict to see an increase in the RR of La Macha compared to the first assays, however it may take several generations of continued selection to observe this. Additionally, we extracted DNA from survivors of the first assay to be sequenced and screened for known resistance polymorphisms. Alignment of PCR sequences is currently underway to scan for these mutations. Analysis of DNA samples will help improve our understanding of mechanisms associated with the observed differences in mortality of the bottle assays. The results of this study will be important to consider when proceeding with future methods of mosquito control.

UPDATE ON THE INSECTICIDE RESISTANCE PROFILE OF *AEDES AEGYPTI* FROM CENTRAL AMERICA AND THE CARIBBEAN

Nelson Grisales[1], Dereje Dengela[1], Melany Murillo[1], Sayra Chanquin[1], Gabriel Orellana[1], Lorence Jean[1], Gavino Guzman[1], Magdiel Rivera[1], Sara Brujan[1], Denis Escobar[2], Zoraida Morales[3], Eduardo Romero[4], Jean F. Lemoine[5], Allison Belemvire[6], Carolina Torres Gutierrez[1]

[1]Abt Associates, Rockville, MD, United States, [2]Secretaria de Salud Honduras, Tegucigalpa, Honduras, [3]Ministerio de Salud Publica y Asistencia Social de Guatemala, Ciudad de Guatemala, Guatemala, [4]Ministerio de Salud de El Salvador, San Salvador, El Salvador, [5]Ministère de la Sante Publique et de la Population, Port au Prince, Haiti, [6]United States Agency for International Development, Arlington, VA, United States

The 2015 Zika outbreak in Latin America and the Caribbean made evident the need to strengthen vector control strategies in the region. The mosquito, *Aedes aegypti,* which also transmits dengue, chikungunya, and yellow fever, is usually controlled by integrated strategies, including the use of insecticides to contain outbreaks and reduce the density of adult mosquitoes. However, in most countries of Central America and the Caribbean, the efforts to understand the levels of susceptibility of the local populations of these mosquitoes have been sporadic and incomplete. Here, a complete screening of the susceptibility of *Aedes aegypti* mosquitoes from El Salvador, Honduras, Guatemala, Dominican

Republic and Haiti by using the WHO and CDC methods is presented. The insecticides tested were the pyrethroids, permethrin, deltamethrin, lambda-cyhalothrin and etofenprox; the organophosphates, malathion and pirimiphos-methyl, and the carbamate, bendiocarb. The susceptibility to the larvicide temephos, the growth regulators methoprene and diflubenzuron, and a commercial formulation of the biolarvicide *Bacillus thuringiensis israelensis* (Bti) was also evaluated. In general, resistance to all pyrethroids is high and widely distributed, tolerance to organophosphates is incipient and there is full susceptibility to the only carbamate tested. The susceptibility to temephos varied depending on the region: in Central America the levels of resistance were high, while in Dominican Republic and Haiti levels were low-moderate. Methoprene and diflubenzuron caused similar lethality to reference and field strains, indicating no resistance. Finally, the commercial formulation of Bti was lethal even below the application dose. The current widespread practice in the region is the use of pyrethroids and temephos to control adult and immature mosquitoes, attributing to the high tolerance levels. These results will contribute to making informed decisions and updating the *Aedes* mosquito control strategies at national and regional levels, as well as stimulate the establishment of national and regional insecticide resistance networks.

1564

YEAST-ENCAPSULATION OF CITRUS-DERIVED ESSENTIAL OILS AS AN ENVIRONMENTALLY FRIENDLY LARVICIDE

Michael J. Workman[1], Scott Matthews[1], Linnea Ista[2], Fernando Genta[3], Ravi Durvasula[4], Ivy Hurwitz[1]

[1]University of New Mexico Health Science Center, Center for Global Health, Albuquerque, NM, United States, [2]University of New Mexico, Center for Biomedical Engineering, Albuquerque, NM, United States, [3]Oswaldo Cruz Institute, Rio de Janeiro, Brazil, [4]Loyola University Medical Center, Maywood, IL, United States

Larvicides are an integral part of any vector-borne disease control program. Widely used chemical and bacterial larvicides are limited in efficacy and sustainability by cost, toxicity to humans and other non-target species, rapid evolution of resistance, and degradation of the aquatic environment. Recent increases in dengue fever and Zika virus transmission underscore the urgent need for a safe, effective, low cost mosquito larvicide suitable for use in urban areas. Here we report on the production and evaluation of a novel larvicide made from non-toxic, inexpensive food-grade materials (baker's yeast and essential oil). While essential oils (EO) are recognized as cidal to a broad spectrum of mosquito larvae, dispersing EO directly into aquatic environments is problematic due to cost, UV degradation, and environmental disruption. Our approach obviates these limitations by encapsulating EO in baker's yeast, and feeding these yeast microcapsules to larvae. Once ingested, enzymes in the larval gut digest the capsule, releasing EO and killing the larvae. Our presentation describes a method modified to produce yeast microcapsules with 30-40 wt% loading of EO from *Citrus reticulata* (Mandarin orange) and *C. sinesis* (Sweet orange). Laboratory trials with both encapsulated EOs showed dose-dependent killing with an LD_{50} of 30 mg L^{-1} within 24 hours of treatment. Similar results are observed with encapsulated EO components: R-limonene, γ-terpinene, and myrcene. Larvicide treatment is completed without dispersal of EO into the aquatic environment: the yeast microcapsules are produced without surface residues, segregate EO from the aquatic environment, and are directly ingested by the target species. Our presentation includes the results of lab-scale and preliminary field-testing of this novel larvicide, as well as detailed physical and chemical characterization of the microcapsules.

IMPROVING THE EVIDENCE BEHIND ENTOMOLOGICAL THRESHOLDS FOR INTEGRATED VECTOR MANAGEMENT OF WEST NILE VIRUS

Pascale C. Stiles, Christopher M. Barker

University of California Davis, Davis, CA, United States

The vector index (VI) is used to estimate the relative abundance of arbovirus-infected female mosquitoes. For zoonotic pathogens with complex transmission cycles such as West Nile virus (WNV), the VI is being used increasingly to guide vector control programs as an entomological indicator of human infection risk. Despite its frequent use by mosquito control programs, there is no established VI threshold below which transmission to humans would not be expected. To provide better evidence for this threshold, we characterized the relationship between VI and human WNV disease incidence using surveillance data from several vector control programs, each encompassing one or more counties across the state of California. We used Poisson models to identify optimal demographically-adjusted VI thresholds for cities within each county and examined the predictive value of VI at different spatial scales to determine whether VI is capable of providing sensitive and specific predictions of human WNV disease incidence at scales relevant for vector control. We found the relationship between VI and human WNV disease incidence to vary greatly by county, with predicted human incidence for any particular value of VI being higher in agricultural areas than in urban areas. Accordingly, the optimal VI threshold for predicting incipient high-incidence periods in agricultural counties was lower than in more urban counties. Comparisons of predictive performance across spatial scales pointed to the city level as being the smallest spatial unit for which predictions were reliable enough for operational use. We aim to use these results to develop an interactive tool that vector control programs can use to estimate city-specific human WNV risk to inform decisions on when and where to target broad-scale mosquito control measures.

1566

LOSS OF PYRETHROID RESISTANCE IN *AEDES AEGYPTI* FROM SOUTHERN MEXICO AFTER EIGHT GENERATIONS WITHOUT INSECTICIDE EXPOSURE

Farah Z. Vera-Maloof[1], Karla L. Saavedra-Rodriguez[1], Ashley Janich[1], Francisco Solis-Santoyo[2], Alma D. Lopez-Solis[2], Patricia Penilla-Navarro[2], Americo Rodriguez[2], Pablo Manrique[3], Felipe Dzul[4], William C. Black[1]

[1]Colorado State University, Fort Collins, CO, United States, [2]Centro Regional de Investigacion en Salud Publica, Tapachula, Mexico, [3]Universidad Autónoma de Yucatán, Mérida, Mexico, [4]Centro Nacional De Programas Preventivos y Control De Enfermedades, Mexico City, Mexico

We examined 8 insecticide resistant *Aedes aegypti* mosquito colonies collected from Southern Mexico. Colonies were maintained in laboratory conditions for 8 generations without exposure to insecticides. We screened each generation for the loss of pyrethroid resistance by using PCR-Melting curve to genotype 2 knockdown resistant mutations correlated with pyrethroid resistance in the voltage gated sodium channel; Val1016Ile and Phe1534Cys. Ile1016 allele frequencies ranged from 0.35-0.83 in the F1 generation and 0.31-0.63 in F8. Cys1534 allele frequencies were between 0.67-1.0 in F1 and 0.29-0.99 in F8. We used Fisher's natural selection model for recessive alleles to determine the fitness coefficient for 3 genotypes at each loci which allowed us to predict the evolution of susceptibility for each site. Sites behaved differently since the initial frequencies of the resistant alleles varied. High levels of initial resistance take more generations to become susceptible again. We used bottle assays to evaluate the concentration needed to kill 50% of the population (LC_{50}) for permethrin and deltamethrin in F3, F6 and F8. The resistance ratios (RR) for permethrin ranged from 11.23-49.85 and 1.85-26.18 fold for F3 and F8, respectively. For deltamethrin the RR ranged between 5.79-97.98

and 0.18-36.67 in the F3 and F8, respectively. The RR for both pyrethroids decreased over 8 generations with a stronger effect on deltamethrin. We evaluated F3, F6 and F8 for different life history traits such as number of eggs laid (fecundity), number of hatched eggs, pupation time, adult emergence and sex ratio. Fecundity showed a negative correlation with Ile1016 allele frequencies, Cys1534 allele frequencies and RR of both pyrethroids. This data suggests that there is a fitness cost for resistance, which effects fecundity. However, it is possible to recover susceptibility in resistant mosquito populations. Using Fisher's natural selection model, along with surveillance data, will help improve strategies for mosquito control by calculating the time needed without exposure to insecticides in order to become susceptible for a specific field population.

1567

NOVEL STRATEGIES TO ANALYZE INSECTICIDE RESISTANCE GENES OF LATIN AMERICAN MALARIA VECTORS

David Castañeda[1], Ana C. Benedict[1], Juan C. Lol[2], Mabel Taracena[3], Audrey Lenhart[4], Pamela Pennington[3], Norma Padilla[2]

[1]Universidad del Valle de Guatemala, Guatemala, Guatemala, [2]Center for Health Studies, Universidad del Valle de Guatemala, Guatemala, Guatemala, [3]Biotechnology Center, Universidad del Valle de Guatemala, Guatemala, Guatemala, [4]United States Centers for Diseases Control and Prevention, Atlanta, GA, United States

Malaria is still an important problem for public health in Latin America, and the development of insecticide resistance poses a major threat to the malaria elimination efforts. Monitoring of insecticide susceptibility, combined with the determination of the molecular mechanisms involved in the insecticide resistance, are needed to effectively deploy the appropriate vector control measures. To determine these mechanisms, target site mutations and changes in metabolic enzyme expression have to be analyzed. Novel primers were designed and validated to develop PCR assays that amplify the voltage-gated sodium channel (*VGSC*) and acetylcholinesterase-1 (*Ace-1*) genes in four malaria vectors from Latin America: *Anopheles albimanus, An. darlingi, An. vestitipennis* and *An. pseudopunctipennis*. Also, a quantitative PCR to determine gene expression of the CYP6 genes was implemented using degenerate primers to analyze if cytochrome oxidases are involved on the insecticide resistance of *An. albimanus* populations. The conventional PCR assays and a new qPCR assay were validated to analyze the region of the *VGSC* and *Ace-1* genes associated with insecticide resistance for *An. darlingi*, *An. vestitipennis* and *An. pseudopunctipennis* Quantitative PCR of the P450 CYP6 gene family was developed to assess relative expression in *An. albimanus* laboratory strains. Direct sequencing of PCR products and melt curve analysis confirmed the specificity of the primers to analyzed these resistance mechanisms. Additionally, specific and degenerate primers for the P450 cytochrome families (CYP6, CYP9 and CYP4) were designed for the anophelines vectors to identify possible P450 genes involved in insecticide resistance. The development of these PCR assays presents an important first step in the analysis of molecular mechanisms of insecticide resistance in field populations, allowing for better characterization of insecticide resistance in poorly characterized anopheline species relevant for malaria elimination in Latin America.

1568

CONSTANT SPATIAL PATTERNS OF HIGH DENSITY OF *AEDES AEGYPTI* EGGS AND THEIR CORRELATION WITH SURROUNDING ROOFED AREA OBTAINED FROM SATELLITE IMAGES

Adrian Vasquez-Mejia[1], Johans A. Arica-Gutierrez[2], Edwar J. Pozo[3], Salvador Villegas-Tirado[4], Monica Melendez-Maron[5], Carlos Culquichicón[1], Andres G. Lescano[1]

[1]Emerge, Emerging Diseases and Climate Change Research Unit, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]National Center for Epidemiology, Control and Prevention of Diseases, Lima, Peru, [3]Department of Sanitary Intelligence, Dirección Regional de Salud, Piura, Peru, [4]Department of Health Interventions, Sub Region de Salud Luciano Castillo, Sullana, Peru, [5]Department of Epidemiology, Sub region de salud Luciano Castillo, Sullana, Peru

Vector control of immature forms of *Aedes aegypti* is the main preventive measure of urban arbovirosis such as dengue, Chikunguya and Zika. Identifying and predicting high risk clusters through ovitraps surveillance can improve national strategies aimed at prevention and control. The objective of this study was to characterize the temporal-spatial patterns of egg density of *Ae. aegypti* monitored by ovitraps and to correlate these patterns with surrounding roofed area in Sullana, Peru (pop = 317 443), an endemic area of dengue. Density of *Ae. aegypti* eggs was obtained from the surveillance of 273 ovitraps located in 200 m sided squares monitored weekly in Sullana during 2017. Roofed area was measured in 144.34 m sided hexagons containing at least one ovitrap using satellite images of Sullana from 2017 captured by the RapideEye satellite with a spatial resolution of 5 m on each side, and downloaded from the website www.planet.com (free license). The space-time patterns were defined using Gi * Getis-Ord space-time statistic . The percentage of roofed area between clusters of high and low density of *Ae. aegypti* eggs was compared using T-student test and log-binomial regression implemented with generalized linear models. 186 hexagons with ovitraps were analyzed, 58 of which remained constant clusters in time, resulting in 18 and 40 clusters with high (HDE) and low (LDE) density of *Ae. aegypti* eggs, respectively. The percentage of roofed area between HDE and LDE clusters was different (p = 0.00). The regression analysis showed that, when the percentage of roofed area increased, the prevalence of HDE clusters increased, PR = 1,038 (95% CI 1.005 - 1.071) and the prevalence of the LDE clusters decreased, PR = 0.968 (95% CI 0.951 - 0.985). These findings suggest that roofed area obtained from satellite images is directly associated with the constant presence of a high amounts of *Ae. aegypti* mosquitoes. This knowledge could be useful to identify and predict high risk areas, as well as to design interventions with an effective resources allocation. This methodology might be applicable for the prevention and control of other diseases transmitted by tropical vectors.

1569

THE GENETIC BASIS FOR OUTDOOR HOST-SEEKING BEHAVIOR IN *ANOPHELES COLUZZII* DURING THE BIOKO ISLAND MALARIA CONTROL PROJECT

Jacob I. Meyers[1], Giri Athrey[1], Godwin Fuseini[2], Abrahan Matias[2], Guillermo Garcia[2], Hans Overgaard[3], Vani Kulkarni[1], Vamsi Reddy[1], Christopher Schwabe[2], Immo Kleinschmidt[4], Michel Slotman[1]

[1]Texas A&M University, College Station, TX, United States, [2]Medical Care Development International, Silver Spring, MD, United States, [3]Norweigian University, As, Norway, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom

Nationwide vector control programs have been created to reduce malaria transmission across Africa. These programs largely rely on indoor application of insecticides through the use of long-lasting insecticide treated bed nets and indoor residual spraying of insecticides. However, the efficacy of these control tools is threatened by behavioral resistance in which mosquitoes avoid insecticides applied indoors by host-seeking outdoors. One region where increased outdoor host-seeking has been documented is Bioko Island, Equatorial Guinea, where the Bioko Island Malaria Control Project has conducted IRS based vector control since 2004. We examined if behavioral resistance of *Anopheles coluzzii* on Bioko represents an adaptive response to continued IRS. Using a pool-seq approach with large sample sizes (286-1009 mosquitoes/pool) sequenced to a high coverage (average 421-733x/pool), we compared the genomes of indoor and outdoor host-seeking *An. coluzzii* from 2009, 2013/2014. This allows us to identify genetic variation underlying indoor vs outdoor host-seeking. Secondly, we compared pre-intervention *An. coluzzii* collected in 2004 to the post-intervention samples to identify loci under positive selection during the vector control program. Our analyses are

based on identified between 12.6 and 27 million SNPs we identified in our samples. To determine which SNPs have significantly differentiated allele frequencies between groups, we simulated the sampling effects of pool size and coverage level on F_{ST} estimates. We fit these simulated data with a multivariate exponential model which provided the significant threshold for each SNP. Additionally, we are screening for genes containing significantly differentiated SNPs across multiple groups and replicates. Using these methods, we have identified sites associated with indoor/outdoor host-seeking, although a specific mechanism is not currently clear. If outdoor host-seeking does indeed have a genetic basis, ongoing work using this high-powered poolseq approach will identify exophagic alleles responsible for this adaptation.

1570

SURVEY FOR VIRAL SYMBIONTS IN MOSQUITOES FROM TEXAS, USA AND THEIR INFLUENCE ON VECTOR COMPETENCE OF ZOONOTIC ARBOVIRUSES

Estelle Martin[1], Selen Garcia-Luna[1], Andrew Golnar[1], Wendy Tang[1], Monica Borucki[2], Megan Wise de Valdez[3], Matthias Frank[2], Gabriel Hamer[1]

[1]Texas A&M University, College Station, TX, United States, [2]Lawrence Livermore National Laboratory, Livermore, CA, United States, [3]Texas A&M University, San Antonio, TX, United States

The emergence and re-emergence of mosquito-borne diseases such as Zika, chikungunya and dengue fever remain a global public health challenge that threatens many communities in tropical and subtropical regions of the world. These viruses are driven principally by *Aedes aegypti* mosquitoes and naturally-occurring microbes are intrinsic factors that can influence the ability of mosquitoes to transmit viruses. Additionally, microbial symbionts offer opportunities for innovative vector control strategies such as the way in which *Wolbachia* plays a role in creating populations refractory to the transmission of certain zoonotic arboviruses. Our objective was to identify viral symbionts (i.e. insect-specific viruses) in mosquito vectors from different regions of Texas, USA focusing on: *Aedes aegypti*, *Aedes albopictus,* and *Culex quinquefasciatus*. Our preliminary results showed the presence of cell fusing agent virus (CFAV) and Aedes flavivirus (AeFLAV) in *Ae. aegypti* and *Ae. albopictus* from San Antonio, TX. CFAV was also detected in *Ae. aegypti* populations from the Lower Rio Grande Valley of South Texas. Variation was observed in the minimum infection rate (MIR) according to the different locations reaching up to 178 per 1000 mosquitoes for CFAV and 155 per 1000 mosquitoes for AeFLAV. Additionally, *Culex quinquefasciatus* mosquitoes from College Station, TX were found positive for Culex Flavivirus (CxFLAV), with a low MIR of 0.1 per 1000 mosquitoes. In an effort to understand the interaction of these viral symbionts with human pathogens, we are colonizing populations of these naturally infected ISFs mosquitoes from Texas and conducting co-infection and transmission experiments with arboviruses of human health concern.

1571

HIGH RISK OF MALARIA TRANSMISSION BY *NYSSORHYNCHUS DARLINGI* IN THE MAZAN DISTRICT, IN THE PERUVIAN AMAZON

Marlon P. Saavedra[1], Freddy Alava[2], Catharine Prussing[3], Carlos Fernandez[1], Carlos Tong[1], Carlos Valderrama[2], Joseph M. Vinetz[4], Jan E. Conn[5], Dionicia Gamboa[1], Marta Moreno[4]

[1]Laboratorio ICEMR-Amazonia, Laboratorios de Investigacion y Desarrollo, Facultad de Ciencias y Filosofia, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Ministry of Health, Iquitos, Peru, [3]Department of Biomedical Sciences, School of Public Health, State University of New York-Albany, Albany, NY, United States, [4]Division of Infectious Diseases, Department of Medicine, University of California San Diego, San Diego, CA, United States, [5]Wadsworth Center, New York State Department of Health, Albany, NY, United States

Malaria remains an important public health problem in Peru, where cases have increased since 2011. Over 52,000 cases were reported in 2017, with *Plasmodium vivax* being the predominant species (76%). *Anopheles* (now *Nyssorhynchus*) *darlingi* is the main malaria vector on the Mazan river, Loreto Department. However, in this area little is known about its behavior and how it affects the dynamics of malaria transmission and/or the efficacy of vector control strategies. To assess vector bionomics, five surveys were conducted in four communities in the Napo and Mazan micro-basins, Amazonian Peru in 2016-2017 and seasonal abundance, Human Biting Rate (HBR), Entomological Inoculation Rate (EIR) and Human Blood Index (HBI) were quantified. *Nyssorhynchus darlingi* accounted for 95% of the species collected (6,762/7,118 mosquitoes). Ninety-one specimens (1.6%) of *Ny. darlingi* were positive for *Plasmodium* sporozoites (*P. vivax* VK210/VK247 or *P. falciparum*) of 5,870 tested for sporozoite detection by ELISA assays. The highest EIRs were detected outdoors in March (4.54, Visto Bueno), and June (3.60, Urco Miraño; 3.52, Libertad); and indoors in June (3.05, Visto Bueno). The Mazan river communities (LIB-VIB) showed the highest HBR (294-568) and EIR (3.52-4.54), whereas the highest IR was recorded at the Napo River (URC: 0.14). The HBI ranged from 0.69 - 0.94; humans were the most common blood source, followed by chickens and cows. In addition, 17% of *Ny. darlingi* collected fed on both humans and chickens. In summary, this study found *Nyssorhynchus darlingi* was the only mosquito species incriminated as malaria vector. Moreover, malaria risk is heterogeneous, with higher transmission outdoors than indoors in Urco Miraño (Napo River) but with similar transmission (outdoors and indoors) in Libertad and Visto Bueno on the Mazan River. Taken together, our results underscore the urgent need for alternative malaria vector control methods of local intervention targeting outdoor-biting mosquitoes.

1572

THE ROLE OF THE MIDGUT BARRIER IN DETERMINING MOSQUITO COMPETENCE FOR ZIKA VIRUS

Hannah J. MacLeod, Yesseinia I. Angleró-Rodríguez, George Dimopoulos

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

During the Zika virus (ZIKV) epidemic the Americas, the vector range of this pathogen was hotly debated. While *Aedes aegypti* was confirmed as the primary vector, conflicting publications on the susceptibility of *Culex quinquefasciatus* called into question the vector-specificity of ZIKV. Understanding which mosquito species are involved in ZIKV transmission, and the mechanisms determining vector competence, is critical to successful vector control. We investigated the susceptibility of *Cx. quinquefasciatus* to ZIKV infection, utilizing multiple mosquito and virus strains, and demonstrated both a laboratory (JHB) and field strain from China to be refractory to infection by diverse ZIKV isolates when exposed via blood meal. However, upon intrathoracic injection of ZIKV, salivary gland infection occurred in JHB strain *Cx. quinquefasciatus*. This demonstrates a midgut barrier to ZIKV infection in JHB *Cx. quinquefasciatus*. We have continued our investigation of this barrier to identify the dynamics of ZIKV in the blood bolus and midgut epithelium of susceptible and refractory mosquito species. *Ae. aegypti* and JHB *Cx. quinquefasciatus* midguts were assayed for ZIKV RNA at 12 hour intervals immediately post infection. Productive viral infection was clear in *Ae. aegypti,* with viral titers dropping quickly after exposure and increasing after an eclipse period. However, no evidence of productive midgut infection was observed in JHB *Cx. quinquefasciatus*. ZIKV RNA was detectable in midguts of this strain early after exposure but quickly dropped below detection. We also detected no infectious ZIKV particles in the blood boluses of JHB *Cx. quinquefasciatus* in the same timeframe, suggesting that the infection barrier occurs rapidly after exposure. Investigation now focuses on the extra/subcellular localization of ZIKV in *Ae. aegypti* and *Cx. quinquefasciatus* mosquitoes during this timeframe. Determining the differing virus-vector interactions between susceptible

and refractory mosquitoes may reveal cellular factors critical to virus infection, and improve understanding of molecular mechanisms of ZIKV infection in susceptible vectors.

1573

MALARIA VECTOR SURVEILLANCE RESULTS IN BURUNDI CALL FOR ENHANCED PREVENTIVE INTERVENTIONS TO CONTROL THE DISEASE

Virgile Gnanguenon[1], Anatolie Ndashiyimiye[2], Gilbert Ntampuhwe[1], Denis Sinzinkayo[2], Lievin Nsabiyumva[3], Mary Hadley[3], Aklilu Seyoum[4], Christen Fornadel[5]

[1]U.S. President's Malaria Initiative, U.S. Agency for International Development VectorLink Project, Abt Associates, Bujumbura, Burundi, [2]National Malaria Control Program, Bujumbura, Burundi, [3]U.S. Agency for International Development, Bujumbura, Burundi, [4]U.S. President's Malaria Initiative, U.S. Agency for International Development VectorLink Project, Abt Associates, Bethesda, MD, United States, [5]U.S. President's Malaria Initiative, U.S. Agency for International Development, Washington, DC, United States

Malaria remains the leading cause of mortality in Burundi. In 2016, the number of cases reached 8.6 million, out of a population of 11 million. Vector surveillance was implemented in sentinel sites to assess local vector behavior and infectivity to inform the country's vector control program. From December 2016 through November 2017, 12 entomological surveys were conducted in eight sentinel sites. Among the 64,799 human-biting mosquitoes collected, five primary vectors were molecularly identified, *Anopheles arabiensis*, *An. gambiae*, *An. coluzzii, An. funestus* and *An. leesoni*. The biting activity of these vectors significantly increased from 12 am to 5 am in comparison to the first half of the night (from 6 pm to 11 pm) ($p<0.001$). The indoor density per light trap was 12.86 for *An. gambiae* s.l. and 3.53 for the *An. funestus* group. A parous rate of 82.91% was observed for *An. gambiae* s.l. populations. For the *An. funestus* group, the parous rate was 83.66%. The lowest parous rate of 74% was observed at the indoor residual spraying site (Kiremba). The average sporozoite rate observed was 1.81% (66/3648). The monthly variations of entomological inoculation rate (EIR) demonstrated that there are two main malaria transmission seasons in the country. The first transmission season occurred between February and June (range: 5-31 infective bites/person/month) and the second occurred from September to December (range: 7-15 infective bites/person/month). The annual EIR varied among sentinel sites with 0 infective bite/person/year at Matana, 6.90 infective bites/person/year at Kiremba, 14.80 infective bites/person/year at Mabayi, 31.35 infective bites/person/year at Gihofi, 70.63 infective bites/person/year at Vumbi, 80.33 infective bites/person/year at Mpanda, 81.02 infective bites/person/year at Nyanza-Lac, and 265.95 infective bites/person/year at Cankuzo. Significant reduction of the EIR was observed after IRS at Cankuzo (42.58 infective bites/person/month before versus 1.75 infective bites/person/month after IRS; $p=0.038$). These results showed that IRS interventions are having a positive impact on malaria transmission in Burundi.

1574

SIGNIFICANT REDUCTION OF MALARIA VECTOR TRANSMISSION FROM 2001 TO 2016 IN MALI: A REAL FUTURE FOR NON-SEVERE MALARIA

Alpha S. Yro[1], Adama Dao[2], Boubacar Coulibaly[2], Bernard Sodio[3], Moussa Diallo[2], Abdramane Fofana[2], Constance Souko[3], Sekou F. Traore[2]

[1]Malaria Research and Training Center, International Centre for Research Excellency in Mali FMOS Point G ; Faculty of Sciences and Technics of the University of Sciences Technics and Technologies of Bamako, Bamako, Mali, [2]Malaria Reseach and Training Center, International Centre for Research Excellency in Mali FMOS, Bamako, Mali, [3]Faculty of Sciences and Technics of the University of Sciences Technics and Technologies of Bamako, Bamako, Mali

Malaria in the Sahel occurs typically over a short period of three months, targeting aestivating mosquitoes could reduce the early *rounds* of vector-human amplifications and potentially reduce malaria transmission exponentially. An integrated fight against malaria since *Plasmodium falciparum* resistance to chloroquine has been undertaken in Mali, to slow down malaria burden. In the current study we compared malaria vector transmission data collected in two endemic areas: Bandiagara and Toukoro. In the first site data were collected prior to the intensive dissemination of ACTs and the policy of large-scale free distribution of long-lasting mosquito treated nets. In the second site, data were collected 15 years after, when ACTs and free MTNs distribution take place. Results comparison show a significant reduction of Entomological Inoculation Rate, EIR from 15 infective bites per man per month in Bandiagara in 2001 to 0.27 infective bites per man per month in 2016 in Toukoro. The reasons for this significant reduction of vector transmission level could be due not only to the political authorities' involvement, but especially because of population's massive adhesion to the global integrative strategy of the fight against this disease. That show positive impact of collaboration between scientists, heath centers, communities and decision makers.

1575

THE IMPACT OF CO-CIRCULATING PARASITES ON WEST NILE VIRUS TRANSMISSION

Andrew Golnar[1], Estelle Martin[1], Selene Garcia-Luna[1], Matthew Medeiros[2], Gabriel Hamer[1]

[1]Texas A&M University, College Station, TX, United States, [2]Pacific Biosciences Research Center, University of Hawaii Manoa, Honolulu, HI, United States

Interspecific interactions between parasites are known to influence population and community epidemiology. *Culex* mosquitoes ingest a variety of viral, protozoan, and macro-parasitic organisms that circulate among avian and mammalian hosts, however, the epidemiological consequences of mosquito co-infection on vector-borne transmission remains largely unknown. Using controlled experimental transmission studies we assessed how avian malaria co-infection impacts vector survivorship and the ability for vectors to transmit West Nile virus (WNV). *Culex quinquefasciatus* mosquitoes colonized from Texas were artificially exposed using membrane feeders to *Plasmodium relictum,* propagated in domestic canaries (*Serinus canaria*), and strains of West Nile virus isolated in Texas in combinations of sequential and concomitant infection. Results from these controlled transmission assays were used to parameterize multi-host, multi-vector compartmental models and assess how avian malaria may impact West Nile virus transmission dynamics at population and community scales. Transmission heterogeneity was evaluated using stochastic simulations and sensitivity analyses employing a Latin Hypercube sampling design. Results highlight the importance of considering co-circulating parasites, such as avian malaria, when evaluating the spatial and temporal risk of WNV transmission and further enrich our broader understanding of mechanisms that drive vector-borne disease heterogeneity.

1576

A NOVEL APPROACH FOR PRODUCING FIELD-BASED ESTIMATES OF *ANOPHELES GAMBIAE* BITING BEHAVIOR AND DISPERSAL ABILITY

James Orsborne[1], Abdul R. Mohammed[2], Yaw A. Afrane[2], Thomas Walker[1], Laith Yakob[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]University of Ghana, Accra, Ghana

Mosquito-borne diseases cause a significant burden on human populations in the tropics. Distribution of these diseases is governed by a complex mix

of genetic, environmental and social factors which in turn affect pathogen, vector and host interactions. Different mosquito species show a variety of host biting behaviors. Some species show an extreme preference for human blood over other non-human blood meal sources. As a result, their influence on the transmission of human vector borne diseases is highly significant. However, even the most anthropophilic of disease vectors will source a proportion of their blood meals from non-human hosts. A novel, field-based method to inform the plasticity in the vector's choice of blood-host using strategically located mosquito traps for *Anopheles gambiae* has been developed. We present the first estimates for the remarkably local spatial scale across which this behaviour is plastic and provide novel data on mosquito dispersal behavior post feeding. This novel experimental set up informs two aspects of vector behaviour in the field which are imperative to disease transmission and for which current estimates are lacking for all major vector species'.

1577

INSERTION OF OIL PALM INTO FOREST IN BORNEO NARROWS MOSQUITO DIVERSITY BUT FAVORS A KEY VECTOR OF SYLVATIC DENGUE VIRUS

Katherine I. Young[1], David Perera[2], Nikos Vasilakis[3], Yvonne Linton[4], Michaela Buenemann[5], Kathryn Hanley[1]

[1]Department of Biology, New Mexico State University, Las Cruces, NM, United States, [2]Institute of Health and Community Medicine, Universiti of Malaysia Sarawak, Kota Samarahan, Malaysia, [3]Department of Pathology and Center for Biodefense and Emerging Infectious Disease, University of Texas Medical Branch, Galveston, TX, United States, [4]Walter Reed Biosystematics Unit, Smithsonian Institution, Suitland, MD, United States, [5]Department of Geography, New Mexico State University, Las Cruces, NM, United States

Notable arboviruses including dengue (DENV), chikungunya, and Zika, emerged into human transmission via spillover from sylvatic transmission cycles maintained between non-human primates and *Aedes* mosquitoes in tropical forests. These ancestral sylvatic strains continue to circulate and to spill over into the human population in present day. To forestall emergence of novel virus strains from these sylvatic cycles, it is crucial to identify the environmental factors that shape the likelihood of spillover. Sarawak, Borneo, a known focus of sylvatic DENV transmission, is undergoing rapid land cover change, particularly insertion of oil palm plantations into forests. We hypothesized that this land cover conversion would alter the diversity, abundance, and distribution of mosquitoes and thereby influences rates of spillover. We tested four predictions: (i) mosquito diversity and abundance would decline in plantations; (ii) mosquito diversity would be greatest at the forest edge iii) *Aedes albopictus*, an opportunistic vector of DENV, would occur in equal abundance in plantations and forest, (iv) *Ae. niveus,* a canopy-living vector of sylvatic DENV, would be most abundant in forests. Adult mosquitoes were collected at 34 sites each at 10 distances from interior oil palm to interior forest in Sarawak. In total, 894 mosquitoes comprising 24 genera were collected. Genus-level mosquito richness and diversity increased with distance into forest and sites 100 m into the forest were the most diverse, contrary to our prediction. Mosquito community composition was different between distances sampled, but remained more similar from 10 m up to 500 m. Mean mosquito abundance declined significantly in interior plantation; however, as predicted there was no difference in the mean number of *Ae. albopictus* sampled at any distance. While rare, *Ae. niveus* were only found at least 10m into the forest, supporting our fourth prediction. These data indicate that likelihood of spillover of sylvatic viruses increases with distance into the forest, where more types of potential vector species occur and where mosquito abundance is, on average, higher.

1578

QUANTIFICATION OF MOSQUITO BITING RATES USING SURVEYS AND THEIR IMPLICATION IN DETERMINING DENGUE VIRAL TRANSMISSION RISK IN THE GREATER NEW ORLEANS REGION

Panpim Thongsripong[1], Zhuolin Qu[2], James M. Hyman[2], Dawn Wesson[3]

[1]California Academy of Sciences, San Francisco, CA, United States, [2]Department of Mathematics, Tulane University, New Orleans, LA, United States, [3]Tropical Medicine Department, Tulane University, New Orleans, LA, United States

Over the past decades, *Aedes*-borne viral diseases such as dengue, chikungunya, and Zika have been surging in incidence and threatening to spread to new geographical areas where their mosquito vectors thrive. In order to estimate viral transmission risks in these areas, mathematical modeling is required; and the accurate estimates of the local transmission parameters are essential. One of the most important parameters that determines infection risk is mosquito biting rate. However, this rate is rarely characterized in field settings due to the lack of appropriate and research methods. In this study, mosquito biting rates in two study sites within the Greater New Orleans Region were estimated using a short survey questionnaire to ask study participants about the quantities of mosquito bites they experienced in the past 24 hours. In addition, Human Landing Capture was utilized in the same two areas to estimate the proportions of perceived mosquito bites that belonged to *Ae. aegypti* and *Ae. albopictus*. The results demonstrated significant variations in biting rates between outdoors and indoors and between the two residential areas. Higher exposure to mosquito bites was correlated with the amount of time study participants spent outside during risk periods. There was also a significant effect of study site on bite exposure outdoors, possibly due to the difference in the numbers of host-seeking mosquitoes. An epidemiological compartmental model describing dengue virus transmission was applied to demonstrate how the observed differences in the biting rate of *Ae. aegypti* and *Ae. albopictus* between the two study sites would result in differential dengue transmission risks in these areas. This study highlights a practical research method, the survey questionnaire, that could be used to estimate mosquito biting rates in other locations.

1579

ACOUSTICS BEHAVIOR OF THE MALARIA VECTOR *ANOPHELES ALBIMANUS*

Catalina Alfonso-Parra[1], Sebastian Gomez[1], Hoover Pantoja[2], Viviana Velez[2], Fredy Ruiz[2], Frank W. Avila[3]

[1]Instituto Colombiano de Medicina Tropical, Medellin, Colombia, [2]Programa de estudio y control de enfermedades tropicales (PECET) - UdeA, Medellin, Colombia, [3]Max Planck Tandem Group in Mosquito Reproductive Biology, Universidad de Antioquia, Medellin, Colombia

Malaria is one of the most important mosquito-borne diseases worldwide. In Colombia, 52,954 cases of Malaria were reported in 2017. *Anopheles albimanus* is one the primary vectors of malaria in Colombia, where containment of the disease is currently focused on the use of insecticides and bed nets. However, due to changes in mosquito behavior and an increase in insecticide resistance, it is necessary to develop new methods of control that exploit the biological traits of *An. albimanus*, potentially allowing for more specific targeting of this disease vector. Reproduction is one of the main mosquito biological traits related to vectorial capacity. However, little is known about *An. albimanus* behavior during courtship and mating, including acoustic behavior. Our goal is to better understand the acoustics of *An. albimanus* in order to develop and/or improve tools implemented in vector control. To gain insight into *An. albimanus* swarming and courtship behavior, we are using methods such as artificial vision and acoustic source separation techniques to dissect the basics of mating in this species under laboratory conditions, focusing on swarming

and mating acoustics. We previously described that the fundamental frequency of tethered *An. albimanus* females is 368.9 ±34.2 Hz and 524.11 ±63.7 Hz in males, independent of individual size. Here, we describe the fundamental frequency of individual, free flying females and males, both of which are significantly higher than when individuals are tethered. When measuring the fundamental frequency of groups of males, we observed a unique tone when males display a stereotypical flight. Finally, we characterized the fundamental frequency of pairs of female and male mosquitoes before copulation or rejection. Taken together, these results contribute to our knowledge of *An. albimanus* mating behavior and will potentially aid in future vector control efforts.

VECTOR MOSQUITOES AND COMMUNITY KNOWLEDGE, ATTITUDES, AND PRACTICES DURING HURRICANE RESPONSE AND RECOVERY IN THE UNITED STATES VIRGIN ISLANDS

Krystal R. Seger[1], Amy H. Schnall[2], Joseph Roth[2], Esther M. Ellis[1], Brett R. Ellis[1]

[1]U.S. Virgin Islands Department of Health, Christiansted, Virgin Islands, U.S., [2]Centers for Disease Control and Prevention, Atlanta, GA, United States

In recent decades, the United States Virgin Islands mosquito surveillance, control, corresponding research, and community outreach has been limited and sporadic. As a result, little is known about the USVI's vector mosquito populations and the community's knowledge, attitudes, and practices about mosquitoes. Both are important aspects of a hurricane response and recovery and are relevant after recent Hurricanes Irma and Maria hit the U.S. Virgin Islands on September 6, 2017 and September 19, 2017, respectively. Mosquito surveillance for adult *Aedes aegypti* in response to the Zika epidemic began in February 2017 and is ongoing. Gaps in data remain because of the hurricanes and available funding. Preliminary *Aedes aegypti* surveillance results suggest a population peak at the end of April to early May following dry season, but one year of data is insufficient to establish a trend. We conducted Community Assessments for Public Health Emergency Response (CASPERs) in June 2017, November 2017, and February 2018 to provide household-level community information pre- and post-hurricane. CASPERs were conducted with two-stage cluster sampling. Thirty census blocks were selected with probability of selection proportional to the number of households within the cluster. Teams then systematically selected households within each cluster. An adult resident of selected households was invited to complete the in-person questionnaire. According to the November 2017 CASPER, 87% of households experienced an increase in mosquito biting after the hurricanes. In addition, environmental conditions became more favorable for mosquito breeding and feeding from June to November 2017. Inadequate mosquito population trend information hindered the ability to conduct a more thorough response despite evidence of increased mosquitoes. Understanding mosquito population trends before hurricanes in conjunction with community assessments is critical to an effective hurricane response and re-building mosquito surveillance and control capacities in the U.S. Virgin Islands.

THE ZIKA AIRS PROJECT (ZAP): FIRST YEAR OF ENTOMOLOGICAL SURVEILLANCE AND VECTOR CONTROL USING A BIOLARVICIDE IN COUNTRIES OF LATIN AMERICA AND THE CARIBBEAN

Carolina Torres Gutierrez[1], Dereje Dengela[1], Melany Murillo[1], Tanya Cortez[1], Gabriel Orellana[1], Orlando Urrutia[1], Sayra Chanquin[1], Marianela Menes[1], Lorence Jean[1], Denis Escobar[2], Zoraida Morales[3], Eduardo Romero[4], Jean F. Lemoine[5], Paula Wood[1], Allison Belemvire[6], Nelson Grisales[1]

[1]Abt Associates, Rockville, MD, United States, [2]Secretaria de Salud Honduras, Tegucigalpa, Honduras, [3]Ministerio de Salud Publica y Asistencia Social de Guatemala, Ciudad de Guatemala, Guatemala, [4]Ministerio de Salud de El Salvador, San Salvador, El Salvador, [5]Ministère de la Sante Publique et de la Population, Port au Prince, Haiti, [6]United States Agency for International Development, Arlington, VA, United States

In 2015 and 2016, the Zika virus spread rapidly across the region. The high incidence of this virus, as well as its link with microcephaly in infants, raised international concern and the World Health Organization (WHO) declared a public health emergency in 2016. In response to this emergency, the United States Agency for International Development (USAID) approved additional funds to implement activities to prevent Zika transmission. The Abt-led initiative, Zika AIRS Project (ZAP), is enhancing USAID's ability to build capacity in Latin America and the Caribbean for vector control, working alongside ministry of health officials to prevent Zika transmission through entomological monitoring and vector control strategies. After its first year of implementation, ZAP outcomes include the reduction of *Aedes aegypti* populations at the household level through regular field team visits to conduct environmental cleanup, ento-monitoring and application of a biolarvicide based on *Bacillus thuringiensis*. Targets for the larviciding campaign were wide-ranging, with the smallest coverage targeting 34,000 houses in Haiti, to the most inclusive in Honduras comprising 280,000 households. Complementary strategies to study local *Aedes aegypti* populations involved sentinel site surveillance of egg density using ovitraps with/without hay infusion in 100 houses, and larvae/pupae surveys in 200 houses. The main breeding sites for *Ae. aegypti* are drums, plastic-containers and tires in Haiti, cement tanks or pilas in Guatemala, El Salvador and Honduras; and metal barrels in Guatemala and El Salvador. Results showed higher percentage of eggs when using infusion, in all countries. Density of eggs, pupae, and traditional *Aedes* indexes had a decreasing tendency in all sites across countries after a few weeks post surveillance, and before and after larvicide application. Breteau indexes reached historic low values (1-5) in El Salvador and Honduras post larviciding campaign. ZAP teams have increased the number of trained personnel and invigorated technical capacity for public health entomology in all target countries.

1582

HIGH DIVERSITY OF ANOPHELINES IN OUTDOOR COLLECTIONS IN NCHELENGE DISTRICT, ZAMBIA

Christine M. Jones[1], Jennifer C. Stevenson[1], Ilinca I. Ciubotariu[1], James Lupiya[2], David Mbewe[2], Mbanga Muleba[2], Douglas Norris[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Tropical Disease Research Centre, Ndola, Zambia

Among the major challenges faced in the global drive to eradicate malaria is the existence of previously unrecognized and potential vectors, as well as behavioral plasticity of the major vectors. Because the vast majority of vector interventions are implemented inside sleeping structures, universal coverage of bed nets and indoor residual spray will still leave people vulnerable to residual transmission from exophagic and exophilic vectors. High malaria transmission persists in Nchelenge District of northern Zambia, despite decades of control in the form of artemisinin-combination therapies, indoor residual spray, and bednets. The Southern and Central Africa International Centers for Excellence in Malaria Research (ICEMR) studies this region, as part of efforts to understand the mechanisms underlying persistently high transmission. The major vectors in this region are *Anopheles funestus s.s.* and *An. gambiae s.s.* Very few other species are caught indoors. Outdoor vector activity has not been rigorously studied to date. In order to study outdoor foraging vectors, we used a Latin square design, and rotated households through 3 different 'treatments' on different nights: CDC light traps in adjacent animal pens, CDC light traps indoors near sleeping inhabitants, and CDC light traps with artificial baits adjacent to household entryways. Preliminary analysis has shown that while *An. funestus* was most abundant, a large number of *An. coustani* were also collected in addition to over 10 different other morphological species of anophelines. Ongoing analyses will characterize the transmission

potential of these species in our study area, including CSP ELISA to determine infectious rates and blood meal PCR to determine biting rate and human blood indices.

1583

VECTOR COMPETENCE OF *AEDES ALBOPICTUS* FOR ZIKA VIRUS

Benjamin A. McKenzie[1], Sarah Zohdy[1], Alan Wilson[2]

[1]Auburn University: School of Forestry and Wildlife Sciences, Auburn, AL, United States, [2]Auburn University: School of Fisheries, Auburn, AL, United States

Much work has been done in recent years to determine the vector competency of *Aedes albopictus* (Skuse) for Zika virus (ZIKV). If competent, *Ae. albopictus* could become a very important vector in the spread of ZIKV to more northerly latitudes as well as a link between sylvatic, rural and urban systems. Recent review of the literature surrounding *Ae. albopictus'* competence for ZIKV, while suggestive, provides no quantitative analysis of *Ae. albopictus'* competence, nor does it address the potentially confounding differences between studies. For our study, we undertook a quantitative meta-analysis of the literature surrounding this topic. We examined infection rates (IR) and transmission rates (TR) at 7 and 14 days post infection (dpi) across 9 studies comprised of 26 sub-studies/treatments using a restricted maximum likelihood (REML) model. Our model examined potentially confounding variables in the studies, including freshness of blood meal, origin of viral strain, log transformed viral dosage and whether the viral strain and mosquito population tested came from the same geographic region. Our results suggest that: 1) *Ae. albopictus* is a competent vector for ZIKV, 2) Freshness of blood meal has a large and significant effect on transmission at 7 dpi, 3) Co-occurrence of viral strain and mosquito population has a significant effect on both IR and TR at 14 dpi, 4) East Asian and Oceanic strains of ZIKV are less infective to and transmissible by *Ae. albopictus* than South American and North American strains of the virus. These results indicate a need to re-examine the literature and to revise methods for vector competence studies.

1584

GENETIC DIVERSITY OF *ANOPHELES COUSTANI* IN HIGH MALARIA TRANSMISSION *FOCI* IN SOUTHERN AND CENTRAL AFRICA

Ilinca I. Ciubotariu, Jennifer C. Stevenson, Tamaki Kobayashi, Giovanna Carpi, Christine M. Jones, Douglas E. Norris

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Despite ongoing malaria control efforts implemented throughout sub-Saharan Africa, malaria remains an enormous public health concern. Current interventions such as indoor spraying of insecticides and use of insecticide-treated bed nets are aimed at targeting the primary malaria vectors that are majorly endophagic and endophilic. While these control measures have resulted in a substantial decline in malaria cases caused by these primary vectors, and continue to impact indoor transmission, the importance of secondary vectors for malaria transmission has been neglected. One of these secondary vectors, *Anopheles coustani*, is a species previously believed to exhibit mostly zoophilic behavior. Recent studies from across Africa are bringing to light the contribution of this and ecologically similar anopheline species to human malaria transmission. Like many of these understudied species, *An. coustani* has greater anthropophilic tendencies than previously appreciated, is often both endophagic and exophagic, and carries *P. falciparum* sporozoites. These recent developments highlight the need for more studies in afflicted regions to control this vector. This study analyzed outdoor *An. coustani* mosquitoes captured from high transmission settings in Nchelenge District, Zambia, and Kashobwe Health Zone and Kilwa Health Zone, the Democratic Republic of Congo using CDC light traps and pyrethroid spray catches. Species identifications were determined morphologically and confirmed by sequencing mitochondrial DNA cytochrome *c* oxidase subunit 1 (COI) and ribosomal internal transcribed spacer region 2 (ITS2). Furthermore, blood feeding host preference was determined by PCR and *Plasmodium falciparum* infectivity by ELISA. Maximum parsimony trees were constructed from the aligned sequences and genetic relationships showed three distinct clades. This study presents a more thorough understanding of *An. coustani* genetic diversity and bionomic characteristics, which will enable the development of more effective vector control strategies to limit indoor and outdoor transmission, and ultimately, prevent secondary vectors from becoming primary vectors.

1585

INVESTIGATING THE BIOLOGY AND BEHAVIOR OF *ANOPHELES SQUAMOSUS* AND ITS ROLE IN MALARIA TRANSMISSION IN SOUTHERN ZAMBIA

Jordan E. Hoffman[1], Limonty Simubali[2], Twig Mudenda[2], William J. Moss[1], Douglas E. Norris[1], Jennifer C. Stevenson[2]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Macha Research Trust, Macha, Zambia

In the last decade, malaria cases in Southern Zambia have declined by 90% due in part to national control efforts. Although some areas, such as the Nchelenge District in northern Zambia, still experience high transmission, Choma District in southern Zambia is approaching elimination. In 2011, higher than expected rates of anthropophily was observed among "zoophilic" species in the catchment area of Macha Hospital, including *Anopheles squamosus*, indicating the potential importance of secondary malaria vectors. The importance of *An. squamosus* as a secondary malaria vector was confirmed in 2016 when *Plasmodium falciparum* sporozoites were detected in the species within the pre-elimination zone of southern Zambia. *An. squamosus* have been shown thus far to be mainly exophilic and exophagic (feeding and resting outdoors). If they are feeding on humans outdoors, they may be feeding at different times and in different areas than the primary vectors. If this is the case, new control measures may be necessary for achieving and sustaining malaria elimination. Due to its previously presumed lack of importance to malaria transmission, little is known about the foraging behavior of *An. squamosus*. Mosquito collections were performed at three locations per household—inside a sleeping house, next to a cooking structure, and next to an animal pen—throughout a 24-hour period using primarily CDC light traps. Households were randomly selected among households enrolled in the ICEMR study with animal pens in the Macha area. After collection, mosquitoes were morphologically and molecularly identified, infectivity assessed by CSP ELISAs and blood meal origin determined by PCR. Ecological and human behavioral data were incorporated to evaluate associations between climatic and human population activity with *An. squamosus* population density and behaviors and to determine the level of exposure. Data from these collections will help identify the extent of the role *An. squamosus* has in malaria transmission in southern Zambia, evaluate the efficacy of current vector control methods, and provide data for alternative control strategies.

1586

AMERICAN ROBINS AND COMMON GRACKLES EXPERIMENTALLY INFECTED WITH WEST NILE VIRUS DIFFER IN THEIR INFECTIVENESS TO *CULEX PIPIENS* MOSQUITOES

Jefferson A. Vaughan[1], Elizabeth S. Andrews[2], Juanita M. Hinson[2], Michael J. Turell[2]

[1]University of North Dakota, Grand Forks, ND, United States, [2]United States Army Medical Institute of Infectious Diseases, Fort Detrick, MD, United States

West Nile virus (WNV) is a mosquito-borne arbovirus of songbirds. In nature, songbirds are commonly infected with blood parasites (*e.g.*, microfilariae, haemosporidia, trypanosomes). In certain systems, arboviral infections in microfilaremic hosts have been shown to enhance the

infectivity of arboviruses to mosquitoes. Thus, the original aim of this study was to examine the reservoir competence of WNV-infected birds to mosquitoes, comparing birds with active blood parasitemias versus birds without blood parasitemias. To do this, American Robins and Common Grackles were live-trapped and tested for antibodies to WNV. Only WNV-seronegative birds were used in the study. Birds (six Robins, nine Grackles) were screened by microscopy for microfilariae and trypanosomes and by PCR for haemosporidia. Parasitized and non-parasitized birds were then inoculated with WNV. Groups of *Culex pipiens* mosquitoes were allowed to feed on the birds over the subsequent three nights. Viremia profiles were similar between Robins and Grackles, peaking at Days 1 and 2 after virus inoculation. Within a bird species, the presence or absence of blood parasites had little effect on the infectiousness of WNV-infected birds to mosquitoes. However, WNV-infected Robins and Grackles with comparable viremias differed significantly with respect to their infectivity to mosquitoes. Over a range of viremias, Robins were always more infectious than Grackles. These results suggest that the infection threshold of arboviruses may depend not only on the species combination of virus and vector, but also on host species. Estimates of reservoir competence based solely on the profile of host viremia following viral inoculation may lead to inaccuracies. Estimates of reservoir competence may be more accurately determined by feeding cohorts of vectors on experimentally-infected hosts over a range of viremias and determining the resultant vector infection rates.

1587

IDENTIFICATION OF PUTATIVE MOSQUITO VECTORS IN AN ARBOVIRAL ENDEMIC AREA OF COSTA RICA

Luis M. Romero-Vega[1], Daniel Barrantes[2], Martha Piche-Ovares[1], Claudio Soto-Garita[1], Adriana Troyo[1], Eugenia Corrales-Aguilar[1]

[1]Research Center for Tropical Diseases, University of Costa Rica, San Jose, Costa Rica, [2]Pathology Department, National University of Costa Rica, Heredia, Costa Rica

Costa Rica is an endemic country for several arboviruses. Ostional is a district located in the northwest where wet and dry seasons are clearly marked and with a landscape mainly constituted of tropical dry forest and cattle ranches. Recently, human and equine outbreaks of several arboviruses have occurred in Ostional and its surroundings. Our aim was to capture and identify potential vectors for West Nile Virus (WNV), Madariaga Virus (MADV), and Venezuelan Equine Encephalitis Virus (VEEV). We sampled 8 different estates during one year. Encephalitis Vector Survey (EVS) Traps, CDC Gravid Tramps, and ovitraps were placed in 4 different areas: intradomiciliary, peridomiciliary, pen, and forest. The traps were placed from 18:00 to 6:00 hours. The EVS traps were baited with 2 lbs of dry ice and the CDC Gravid Traps with hay infusion. Even though our sampling effort was limited, we were able to identify several species considered as vectors of WNV and VEEV among other viruses. We collected approximately 25 different species of mosquitoes. The EVS capture success was significantly lower during the dry season than in the wet season, whereas the CDC Gravid Trap success was greater during the dry season. Overall, the most common species captured with the EVS and CDC Gravid Traps during the wet season were *Culex quinquefasciatus* (36.3%), *Deinocerites pseudes* (22.9%), and *Anopheles albimanus* (12.2%); while during the dry season *De. pseudes* (60.0%) was the most common species found. Larvae of *Aedes aegypti* and *Aedes albopictus* were collected in the ovitraps during both seasons. Other species such as *Trichoprosopon digitatum*, a yellow fever vector, were captured only during the dry season. Despite an important drop in the number of mosquitoes and species captured during the dry season, the presence of known arboviral vectors such as *De. pseudes,* may indicate the maintenance of enzootic transmission cycles year-round though with sporadic arboviral spillovers. Further sampling and testing of mosquitoes for different arboviruses presence are required to correctly address arbovirus transmission dynamics in this endemic area.

1588

SEASONALITY OF MALARIA VECTOR ABUNDANCE ALONG IRRIGATION GRADIENT IN BWANJE VALLEY SCHEME IN MALAWI

Wezi E. Mkwaila[1], Edward Walker[2], Charles Mangani[3], Leo Zulu[2], Terrie Taylor[2], Don Mathanga[3], Themba Mzilahowa[3]

[1]Luanar, Lilongwe, Malawi, [2]Michigan State University, East Lansing, MI, United States, [3]University of Malawi, Blantyre, Malawi

Irrigation schemes present a unique challenge when considering malaria control interventions. While many efforts have led to a decline in transmission intensity, the disease continues to be a major public health problem in Malawi. However, these efforts could prove to be inefficient as Malawi increases surface irrigation through the expansion of irrigation schemes. While this is an opportunity to address food insecurity and improve rural livelihoods; it also increases malaria risk through the proximity of vector breeding sites to human residences. Expanding surface water creates more Anopheles breeding habitats, thereby increasing local transmission. We conducted an entomological study to study the vector density and parasite transmission in Bwanje Valley Irrigation Scheme in Dedza, Malawi. Mosquitoes were collected in 14 villages around the Bwanje Valley at the end of the rainy season in April 2016 and 2017 involving 400 households per year. A total of 6700 mosquitoes were collected from 344 households in 2016 and 5300 mosquitoes from 283 households in 2017. These were sampled by indoor CDC light trap without dry ice and played in sleeping rooms. Mosquitoes were identified morphologically and by PCR methods to species. Of the malaria vectors, (in 2016 and 2017 respectively) Anopheles arabiensis (68%; 59%) was the dominant mosquito in collections and Anopheles funestus was second most common (10%; 19%), whilst Culex sp represented 18%; 21% and Mansonia sp represented 2% and 1% of total collections, respectively. An average of 19 mosquitoes per household were collected (5-56 range) per trap-night and six villages had counts above the average. All were close to the scheme. The malaria transmitting species were most abundant in six of the fourteen villages and in these villages. An. funestus was relatively more abundant in four villages only. Mosquito abundance in 2016, a drought year revealed that villages most proximal to the scheme had the highest Anopheles abundance compared to those further away. In 2017 under more abundant rainfall there were more breeding sites resulting in mosquito abundance independent of the irrigation gradient.

1589

APPLICATION OF A NOVEL HIGH-THROUGHPUT MOLECULAR APPROACH FOR VECTOR-BORNE DISEASE SURVEILLANCE TO MALIAN AND GUINEAN MOSQUITOES

Haikel N. Bogale[1], Matthew Cannon[1], Kalil Keita[2], Denka Camara[2], Yaya Barry[2], Moussa Keita[2], Mark Travassos[1], Seth Irish[3], David Serre[1]

[1]University of Maryland, Baltimore, Baltimore, MD, United States, [2]Programme National de Lutte contre le Paludisme, Conakry, Guinea, [3]Centers for Disease Control, Atlanta, GA, United States

Efficient vector-borne disease surveillance is critical for reducing disease transmission and preventing outbreaks. Unfortunately, current surveillance approaches are resource-intensive: the collection of samples is time consuming and requires trained personnel, the vector species identification is laborious, and the detection of pathogens is expensive. As a consequence, efforts typically focus on monitoring only a few specific pathogens associated with the most current threats, which hamper early detection of emerging pathogens. Recently, we developed a PCR-based assay which, combined with high-throughput sequencing, allows the detection and characterization of a large variety of eukaryotic parasites in a single sample. Here, we apply this assay to analyze more than 600 *Anopheles* mosquitoes collected from several locations in Guinea and Mali. We screened each individual mosquito for DNA from *Microsporidia,*

Plasmodium, Spirurida, Trichocephalida, Apicomplexa, Kinetoplastida, Parabaslia, Platyhelminthes and RNA from Arboviruses. In addition, we simultaneously characterized the species of each mosquito, preliminarily assessed the mosquitoes' genetic diversity at the ND5 locus, genotyped insecticide resistance alleles and determined the composition of each blood meal. In this comprehensive approach, we are able to gain insight about the distribution and diversity of both the pathogens and vectors in a high-throughput and cost-efficient manner. This study offers an examination of this assay as a preliminary surveillance tool that can provide a framework for designing targeted methodology to monitor pathogens and vector species.

DIVERSITY OF *ANOPHELES* MOSQUITOES FROM ANTHROPIC LANDSCAPES OF AN ENDEMIC MALARIA REGION OF COLOMBIA

Juan C. Hernandez, Daniel Rincon, Nelson Naranjo, Stiven Quintero, Alba Marin, Margarita M. Correa

Universidad de Antioquia, Medellin, Colombia

The landscape structure influences the distribution and abundance of *Anopheles* mosquitoes. This work aimed to determine the relationship between *Anopheles* diversity with patch number and with landscape diversity in five localities of a malaria endemic region in northwest Colombia. Mosquitoes were collected at six sites per locality; land covers at 1.5 Km radius were characterized using orthorectified aerial photographs and landscape metrics were calculated. The diversity of the *Anopheles* community in each locality was estimated, and a linear regression model was applied to evaluate the relationship between *Anopheles* diversity with the number of patches and the landscape diversity. In general, landscapes with land covers associated with mining and livestock activities were mainly observed. A total of 2,458 mosquitoes were collected and corresponded to 10 species. The highest species richness was registered in Puerto Triana locality, with eight species, and the lowest, in La Lucha and Villa Grande, with five species each. The highest species diversity was registered in Cuturú and Puerto Triana (Simpson 1-D= 0.714 and 0.701 respectively) and the lowest in La Lucha (1-D= 0.239). The linear regression model showed a negative relationship between patch number with *Anopheles* richness (r^2= 0.84; r = -0.92; p<0.05), and with *Anopheles* diversity (r^2= 0.83; r =-0.91; p<0.05). No significant relationship was found between landscape diversity and *Anopheles* diversity (r^2= 0.59; r= 0.77; p>0.05). The results indicate that landscape fragmentation, expressed as the number of patches, influences *Anopheles* diversity. Additionally, they suggest that changes in forest cover associated with human activities exert a selection pressure on the species, favoring the presence of malaria vectors. This information contributes to the planning of vector control interventions.

IMMUNOMODULATORY ROLE OF ARYL-HYDROCARBON RECEPTOR IN INSECTS

Aditi Kulkarni, Wanqin Yu, Jennifer Curtiss, Jiannong Xu

New Mexico State University, Las Cruces, NM, United States

Insect have developed an efficient immune system during the evolutionary interactions with microbes, to defend against various microbial pathogens. The immune homeostasis is well maintained by different negative feedback mechanisms. The aryl hydrocarbon receptor (AhR) is a ligand activated transcription factor. Upon activation, AhR is translocated into the nucleus and transcribe genes for various functions. In this study, we examined the role of insect AhR signaling in immune regulation in mosquito *Anopheles gambiae* and fruit fly *Drosophila melanogaster*. In the mosquito model, we used different chemical AhR modulators to control AhR activation, and RNAi mediated AhR knockdown. When AhR was inhibited by feeding chemical inhibitors, CH223191, StemRegenin1 and 680C91; mosquitoes were more resistant to systemic infection with a bacterium *Serratia* sp. S1. The survival rate increased from 58% (in naïve control) to 75-85% in treated mosquitoes (P<0.01). Similar trends were observed after AhR gene silencing by RNA interference, which resulted in higher survival. On the opposite, when mosquitoes were treated with agonist kynurenine, survival rate was reduced from 58% to 38.7% (P<0.01). In *Drosophila*, the AhR is encoded by gene *spineless, Ss.* There are *Ss* loss of function mutant lines. Bacterium *Providencia* is pathogenic and causes mortality in flies when ingested. The *Drosophila* wild type flies were more sensitive to the oral infection, showing a higher mortality than the two mutant lines, Ss^1 and Ss^a (P<0.01). When wild type flies were treated with an AhR antagonist CH233191, the survival was improved (P<0.05). Furthermore, the interrogation of transcriptome of before and after infections in AhR manipulated mosquitoes revealed various genes that may be involved in the AhR mediated immune regulation. The data indicate that insect AhR plays a role in negative modulation of immunity. In the context of host-microbiota symbiosis, AhR may recognize microbe-derived metabolites and mediate immune tolerance to maintain symbiotic homeostasis.

QUANTIFYING SOCIODEMOGRAPHIC HETEROGENEITIES IN THE DISTRIBUTION OF *AEDES AEGYPTI* AMONG CALIFORNIA HOUSEHOLDS

Marisa A. Donnelly[1], Christopher M. Barker[1], Susanne Kluh[2]

[1]University of California Davis, Davis, CA, United States, [2]Greater Los Angeles County Vector Control District, Santa Fe Springs, CA, United States

The arrival of travelers infected with Zika virus in California and other regions of the U.S. has created an urgent need to understand the genesis of potential local chains of transmission and whether variation in risk can be attributed to socio-demographic factors. Since the first detection of *Aedes aegypti* in Los Angeles County in 2014, the mosquitoes have continued to spread to new cities and have now been detected in 62 cities within the county. Understanding heterogeneities in the distribution of household *Ae. aegypti* abundance is important in estimating the risk of local Zika transmission. We conducted a cross-sectional study in Los Angeles County during summer 2017 to identify heterogeneities in relative household abundance of *Ae. aegypti*. 163 houses were surveyed, representing a wide range of incomes. Surveys consisted of systematic mosquito collections, inspection of the household and property, and administration of a questionnaire in English or Spanish. Households were surveyed on lifestyle and household characteristics, including those that may affect *Ae. aegypti* biting exposure and breeding. We obtained sociodemographic variables, including median income, population density, and property size from the U.S. Census Bureau. Generalized linear models were used to determine whether lifestyle, household, and socioeconomic risk factors were associated with increased *Ae. aegypti* abundance. Overall, 72% of households had *Ae. aegypti* present, 12% of households had *Ae. aegypti* present indoors, and an average of 3.33 *Ae. aegypti* were collected at each household. We found that higher median household income within each household's census tract was associated with lower outdoor *Ae. aegypti* abundance, and was not associated with indoor abundance. We also found that the density of containers with standing water present on properties (number of containers per 1,000 square feet) was the best predictor for *Ae. aegypti* abundance both indoors and outdoors. This study will provide tools for vector control and public health agencies to develop appropriate management strategies for communities at-risk for *Aedes*-borne virus transmission.

IMPACTS OF LARVAL NUTRIENT ENVIRONMENT ON GUT MICROBIOME FORMATION IN *AEDES AEGYPTI*

Sarah M. Short, Hannah J. MacLeod, George Dimopoulos

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

The midgut microbiome is critical for *Aedes aegypti* larval development and can have important implications on vector competence for multiple human pathogens including dengue virus. Given its multifaceted role in vectorial capacity, the microbiome is a prime target for vector control efforts. However, the factors that determine its formation and size are still not well understood. The environment has been shown to play a substantial role in determining microbiome composition. In the current work, we investigate the impact of nutritional availability during larval development on midgut microbiome composition and microbiome size during multiple stages of development. We reared *Aedes aegypti* larvae under four larval food regimes: 0.25mg/larva/day ("low"), 0.75mg/larva/day ("medium"), 1mg/larva/day ("standard"), 2mg/larva/day ("high"). We determined the impact of nutrient availability on body size by measuring wing length in adults from all treatments. We collected DNA samples from larval water, whole 4th instar larvae, sugar fed adult midguts, and blood fed adult midguts 24 hours post blood meal. We performed 16S qPCR to determine the relative level of bacteria in each sample type as well as high-throughput 16S amplicon sequencing to determine composition of the microbiome in each sample type. Adult mosquitoes reared in the low nutrient environment were smaller than those reared in standard nutrient conditions. Preliminary 16S quantification suggests that larvae reared in the low nutrient environment harbor fewer bacteria in their midguts relative to those reared under standard conditions. This persists through adulthood and even after blood feeding, with lower levels of bacteria detected in low treatment adult midguts relative to adults reared in standard conditions. Investigation into differences in microbiome composition are ongoing.

IMPACTS OF TEMPERATURE ON ZIKA VIRUS TRANSMISSION POTENTIAL

Blanka Tesla[1], Leah R. Demakovsky[1], Erin A. Mordecai[2], Matthew H. Bonds[3], Calistus N. Ngonghala[4], Melinda A. Brindley[1], Courtney C. Murdock[1]

[1]University of Georgia, Athens, GA, United States, [2]Stanford University, Stanford, CA, United States, [3]Harvard Mediacl School, Boston, MA, United States, [4]University of Florida, Gainesville, FL, United States

Diseases like Zika, dengue, and chikungunya, which were once considered tropical and sub-tropical diseases, are now threatening temperate regions of the world due to climate change and increasing urbanization. Temperature is a strong driver of vector-borne disease transmission, and characterizing the thermal range and optimum for transmission is crucial for accurately predicting arbovirus emergence and spread. To address the lack of data on the relationship between temperature and key pathogen traits for emerging arboviruses, we conducted a series of experiments to estimate the thermal performance of Zika virus (ZIKV) in field-derived *Aedes aegypti* across eight constant temperatures. We observed strong, unimodal effects of temperature on vector competence, extrinsic incubation period, and mosquito survival. We used thermal responses of these traits to update an existing temperature-dependent R_0 (the basic reproductive number) model, to infer how temperature impacts ZIKV transmission. We demonstrated that ZIKV transmission is optimized at a mean temperature of approximately 29°C, and has a thermal range of 22.7°C to 34.7°C. The predicted thermal minimum for Zika transmission is 5°C warmer than for dengue virus which suggests that current estimates on the global environmental suitability for Zika transmission are over-predicting its possible range. Accurately characterizing the unimodal effect of temperature on emerging arboviruses, like ZIKV, is critical for estimating the potential geographic and seasonal range for transmission, and accurately predicting where future climate change will increase, decrease, or have minimal impact on transmission.

INFECTION DYNAMICS AND DISEASE IN CHIKUNGUNYA VIRUS FIDELITY VARIANT INFECTED MICE

Kasen K. Riemersma, Cody Steiner, Anil Singapuri, Lark L. Coffey

University of California Davis, Davis, CA, United States

Replication fidelity of RNA viruses has evolved to maximize the trade-off between adaptability through genetic diversity and deleterious mutations from error-prone replication. Mutations that modulate replication fidelity have been derived *in vitro* under mutagen treatment for several RNA viruses, including the re-emergent global health threat, chikungunya virus (*Alphavirus*, *Togaviridae*; CHIKV). For CHIKV, mutations in viral non-structural proteins 2 and 4 produce high and low fidelity variants (HiFi and LoFi) with *in vitro* mutation frequencies ranging from 60% to 140% of wild type CHIKV. These fidelity variants can be used to address the gap in knowledge about the effects of replication fidelity on CHIKV fitness and disease. Additionally, high fidelity mutations have been proposed as modifiers of live-attenuated vaccines (LAV) that could improve vaccine safety by reducing the risk of reversion to virulent genotypes. We hypothesized that any deviation from wild type replication fidelity would result in attenuated viral replication and disease, and lower neutralizing antibody titers relative to wild type CHIKV. To test our hypothesis *in vivo*, we inoculated cohorts of 6-week old female C57BL6 mice bilaterally in the rear footpad with CHIKV LoFi, HiFi, double mutant (DM) HiFi, or wild type. We tracked foot swelling and viral titers in tissues and collected serum 30 days post-inoculation. Surprisingly, we found that both HiFi and DM HiFi CHIKV produced more severe foot swelling, but similar viral titers in tissues compared to wild type. Conversely, LoFi CHIKV generated milder footpad swelling than wild type, and lower viral titers. We observed a small reduction in neutralization of WT CHIKV by anti-fidelity variant sera relative to wildtype sera, but no differences in neutralization of fidelity variant CHIKV. These results indicate that fidelity mutations do not necessarily confer an attenuated phenotype for CHIKV in immunocompetent vertebrate hosts.

Chikungunya virus (CHIKV) infection is an arboviral disease, which long term manifestations have been shown to impair durably the health-related quality of life (QoL). Most longitudinal studies of patients affected by chikungunya chronic illness are hospital-based or based on outpatient populations skewed towards selection bias given initial severity at enrolment. In 2015-2016, we assessed the QoL of the general population using a cohort of subjects exposed to CHIKV in 2005-2006 on the island of La Réunion. To achieve this goal, we conducted a telephone follow-up study on a sample of 580 subjects from a population-based

serosurvey (2,442 subjects at inclusion). The primary endpoint was the physical component of the SF-36v2 (PCS). Secondary endpoints were the mental component (MCS) of the SF-36v, as well as SF-36v2 subscales. Painful phenotypes (e.g., musculoskeletal pain, chronic fatigue, or depression), incident morbidities and health care were also measured. Of the 386 responders, the 193 CHIKV-infected individuals had no more musculoskeletal pain, fatigue, or depression than the 193 uninfected individuals 10 years post exposure. The mean PCS score was 66.6 (± 21.6) in the infected and 71.0 (± 19.7) in the uninfected (*P*=0.06) groups. Of the 8 dimensions of the SF-36v2, only bodily pain was impaired in infected subjects compared to uninfected peers (66.7 versus 61.6, *P*=0.04). Infected subjects with pain two years post onset of infection (57%) reported complaints in 88% ten years after: fatigue (57%), mood disorders (46%) and musculoskeletal pain (45%). These symptoms were associated with impairment of all dimensions of SF36v2 QoL for 36% of infected subjects. Indeed, these individuals required rheumatologic care (OR 4.6) or evolved more into osteoarthritis (RR 2.5). Infected subjects did not develop more type 2 diabetes mellitus, cancer, or other known illnesses, than uninfected peers. Ten years after a chikungunya outbreak, infected people have a comparable quality of life than uninfected peers. However, these results are falsely reassuring because more than a third of infected people are sicker and report impaired quality of life.

1597

EXPERIMENTAL EVOLUTION OF CHIKUNGUNYA VIRUS TO STUDY EMERGING VARIANTS AND THE IMPACT OF DEFECTIVE GENOMES ON EVOLUTION

Laura I. Levi, James Lucarelli-Weger, Veronica Rezelj, Pierre Lechat, Veronika Bernhauerova, Annabelle Henrion-Lacritick, Enzo Poirier, Thomas Vallet, Gonzalo Moratorio, Carla Saleh, Marco Vignuzzi

Pasteur Institut, Paris, France

Chikungunya virus has recently extended to previously disease-free areas. Its high mutation and fast replication rates lead to the emergence of new strains potentially able to disseminate in these new territories, through the acquirement of novel characteristics. Favored by a high recombination rate this virus can also produce defective genomes that may interfere with the parental virus and hence influence its evolution. These defective genomes are also known to promote persistence in invertebrate vectors of arboviruses. The La Reunion Island and the Caribbean chikungunya virus strains were passaged several times *in vivo* in their mosquito vector (bypassing the mammalian host) to force invertebrate adaptation. RNA deep sequencing permitted us to select consensus changes or minority variants reflecting invertebrate adaptation. Direct mutagenesis was performed to reproduce these mutations in the virus clone in order to test for attenuation in a vertebrate environment. Interestingly, these repeated *in vivo* mosquito passages give rise to a heterogeneous cloud of defective genomes. Some of them show an interesting shuffled pattern, multiple deletions or duplicated sequences. Contrary to defective genomes produced in mammalian cells that decrease drastically the number of infected mosquitoes after a chikungunya blood meal, these mosquito-derived defective genomes don't seem to decrease viral infection or titer in mosquitoes. Mutations selected by NGS are tested for their impact on the generation and characteristics of these defective genomes. Generation of cloned defective genomes will permit us to compare the impact of mammalian or invertebrate defective genomes on the replication and the evolution of chikungunya virus.

1598

IMMUNOLOGICAL INSIGHTS BASED ON ANTIBODY BINDING EPITOPES ON THE CHIKUNGUNYA VIRUS ENVELOPE

Rachel H. Fong[1], Rebecca Rimkunas[1], Jin Jing[2], Graham Simmmons[2], Michael S. Diamond[3], **Benjamin J. Doranz**[1]

[1]Integral Molecular, Inc., Philadelphia, PA, United States, [2]Blood Systems Research Institute, San Francisco, CA, United States, [3]Washington University, St. Louis, MO, United States

Chikungunya virus (CHIKV) infects millions of people, causing a debilitating arthritic disease with no specific treatment. To identify the CHIKV structures that elicit a protective humoral immune response, we have epitope mapped the binding sites of over 70 monoclonal antibodies (MAbs) against the CHIKV envelope glycoprotein E2/E1 using a comprehensive shotgun mutagenesis library of 910 E2/E1 alanine-scan mutants. Published studies have used these epitopes to characterize broadly cross-reactive and ultrapotent neutralizing MAbs that blocked post-attachment steps, and whose binding mapped to functionally-important domains A or B. MAb binding sites suggest a mechanism of action where MAbs inhibit virus-host membrane fusion by preventing exposure of the fusion loop on E1. Other studies characterized MAbs that induce structural changes on Domains and B, and viral receptor binding residues involved in virus fusion. In addition, we have isolated seven human MAbs against CHIKV E2/E1 derived from infected human patients. The most potent MAb, IM-CKV063, was highly neutralizing (50% inhibitory concentration, 7.4 ng/ml), showed high-affinity binding (320 pM), and was capable of therapeutic and prophylactic protection in multiple animal models up to 24 h post-exposure. Epitope mapping identified an inter-subunit conformational epitope on domain A of E2. Subsequent analyses confirmed this by cryo-EM, and demonstrated that IM-CKV063 blocks both virus entry and virus release steps. The isolated MAbs included previously unreported MAbs against the highly conserved fusion loop. These were broadly cross-reactive against alphaviruses but were non-neutralizing, suggesting that the fusion loop is hidden in mature infectious virions. Analysis of MAbs that bind the E2/E1 spike suggest that the neutralizing epitopes are confined to the exposed topmost and outer surfaces of the E2/E1 trimer, providing a rationale for using the intact E2/E1 trimer for vaccine design and therapeutic MAb development.

1599

UNDERSTANDING THE ROLE OF RECOMBINATION IN ARBOVIRUS EVOLUTION

Veronica V. Rezelj, Dinh Tran, Thomas Vallet, Laura Levi, Marco Vignuzzi

Institut Pasteur, Pasteur, France

Recombination in RNA viruses is a genetic exchange phenomenon that leads to the generation of hybrid RNA molecules from different parental RNA strands. This event, carried out by the viral polymerase as it synthesizes viral RNA, can provide an evolutionary advantage because it can lead to the generation of a new population of viruses with a new genotype and phenotype. These new characteristics may enhance virus replication or enable better adaptation to the host. Importantly, a by-product of recombination is the generation of defective genomes with internal deletions that render them non-replicative *per se*. This poster will focus on the identification of aminoacid residues that regulate recombination in arboviruses, using Sindbis virus as a model. The identified residues were tested for their role in recombination using replicon assays. These results will enable us to generate viruses with lower or higher ability to recombine, which could serve as an invaluable tool to understand the role that genetic recombination may play in arbovirus evolution, transmission or dissemination within the host or arthropod.

PRECLINICAL DEVELOPMENT OF A COMBINATION ZIKA AND CHIKUNGUNYA VIRUS-LIKE PARTICLE VACCINE

Lo Vang, Ben Guenther, Carla Uranga, Jason Mendy, Elena Betancourt, Danielle Thompson, Jayavani Aruri, Jonathan Smith, Jeffery Alexander

PaxVax, Inc., San Diego, CA, United States

Zika virus (ZIKV) and Chikungunya virus (CHIKV) are pathogenic, arthropod-borne viruses that pose serious public health threats to humans. Recently, both viruses have emerged throughout much of the western hemisphere and now circulate globally in many of the same tropical and subtropical geographical regions where the *Aedes aegypti* mosquito vector resides. The unmet medical need and the co-circulation of the viruses in the same geographic regions suggest that a combination vaccine could have public health, commercial, and economic advantages. We have sought to develop a ZIKV and CHIKV combination vaccine based on virus-like-particles (VLPs) generated separately in HEK293 mammalian cells by transient transfection of expression plasmids encoding for ZIKV prME or CHIKV C-E3-E2-6K-E1 structural proteins. VLPs were purified by tangential flow filtration and anion exchange column chromatography. To assess the immunogenicity of the single and combination vaccines, a study was conducted in C57Bl/6 x Balb/c F1 hybrid mice using a dose titration of either ZIKV VLP, CHIKV VLP, or both VLPs formulated with aluminum hydroxide adjuvant. Serum samples from VLP-immunized mice were tested in neutralization assays using reporter virus particles expressing luciferase. The combination VLP vaccine elicited high neutralization titers specific for ZIKV and CHIKV, comparable to antibody titers achieved with either VLP vaccine alone. These results indicate that purified ZIKV and CHIKV VLP can be combined into one vaccine, without inhibitory effects, that has the potential for use in endemic areas. Given the sporadic and unpredictable characteristics of the epidemics caused by these viruses, the demonstration that neutralizing antibody represents a surrogate or correlate of protection for both of these viruses could enable an accelerated approval path to initial licensure.

1601

DEVELOPMENT OF A HIGH THROUGHPUT LUCIFERASE-BASED CHIKUNGUNYA NEUTRALIZATION ASSAY

Jason A. Mendy[1], Matt Hickman[1], Elena Betancourt[1], Danielle Thompson[1], Lo Vang[1], Doug Haney[1], Holly Stoddard[1], Sean Bennett[1], Lisa Danzig[1], Jo Cox[2], Julie Ledgerwood[2], Kimberly Dowd[3], Ted Pierson[3], Barney Graham[2], Marc Gurwith[1], Jonathan Smith[1], Jeffery Alexander[1]

[1]PaxVax Inc., San Diego, CA, United States, [2]Vaccine Research Center, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [3]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

PaxVax, Inc. is developing a virus-like particle (VLP) vaccine candidate intended for active immunization against disease caused by the chikungunya virus (CHIKV). The VLP vaccine has been in-licensed from the National Institutes of Health/Vaccine Research Center (NIH/VRC) and is being further developed with the goal of licensure. To facilitate evaluation of vaccine immunogenicity, PaxVax has developed a high-throughput Luciferase (Luc)-based assay for assessing neutralizing antibody titers against CHIKV (CHIKV-Luc). To aid in the development of the CHIKV-Luc assay, serum samples from the Phase 1 VRC311 study were provided to PaxVax by the NIH/VRC. Evaluation of these samples using the PaxVax method is part of the assay qualification to be completed prior to the company's Phase 2 dose-selection study. The virus used in the assay is the 181/25 vaccine strain of CHIKV that has been engineered to express a Luc transgene. Antibody neutralization titers can be determined via characterization of reductions of Luc activity in the presence of immune serum. We next compared our CHIKV-Luc assay results with those obtained using a flow cytometry-based assay employing a chimeric Semliki Forest-CHIKV OPY1 virus that expresses the green fluorescent protein (GFP). This assay was used previously to characterize the immunogenicity and neutralization breadth of the VLP vaccine in support of the VRC311 Phase 1 study. Finally, both high-throughput assays were compared to the gold-standard plaque reduction neutralization (PRNT) assay using the same immune sera samples from the VRC311 clinical trial. The PRNT assay was evaluated because it was used to test samples in the AFRIMS Philippine field study that established a link between antibody titers and protection: pre-existing PRNT80 titers greater than or equal to 10 protected against symptomatic CHIKV infection (Yoon et al, 2015). Strong and statistically significant correlations were demonstrated between the measurable results for all three assays indicating the feasibility of using the CHIKV-Luc assay for clinical testing of serum samples for CHIKV-specific antibody neutralization activity.
