# Symmetry and Regularity of Extremals of an Integral Equation related to the Hardy-Sobolev Inequality* 

Guozhen Lu and Jiuyi Zhu

December 24, 2010

#### Abstract

Let $\alpha$ be a real number satisfying $0<\alpha<n, 0 \leq t<\alpha, \alpha^{*}(t)=$ $\frac{2(n-t)}{n-\alpha}$. We consider the integral equation $$
\begin{equation*} u(x)=\int_{\mathbb{R}^{n}} \frac{u^{\alpha^{*}(t)-1}(y)}{|y|^{t}|x-y|^{n-\alpha}} d y, \tag{1} \end{equation*}
$$ which is closely related to the Hardy-Sobolev inequality. In this paper, we prove that every positive solution $u(x)$ is radially symmetric and strictly decreasing about the origin by the method of moving plane in integral forms.

Moreover, we obtain the regularity of solutions to the following integral equation $$
\begin{equation*} u(x)=\int_{\mathbb{R}^{n}} \frac{|u(y)|^{p} u(y)}{|y|^{t}|x-y|^{n-\alpha}} d y \tag{2} \end{equation*}
$$ that corresponds to a large class of PDEs by regularity lifting method.

\section*{1 Introduction}

In this paper, we consider a class of integral equations related to the HardySobolev inequality. Let $\alpha$ be a real number satisfying $0<\alpha<n, 0 \leq t<\alpha$,

[^0]$\alpha^{*}(t)=\frac{2(n-t)}{n-\alpha}$. Let $\mathbb{R}^{n}$ be $n$-dimensional Euclidean space. The main purpose of this paper is to study the symmetry and regularity of extremals of the following integral equation:
\[

$$
\begin{equation*}
u(x)=\int_{\mathbb{R}^{n}} \frac{u^{\alpha^{*}(t)-1}(y)}{|y|^{t}|x-y|^{n-\alpha}} d y \tag{3}
\end{equation*}
$$

\]

We will show that solutions to the following differential equation of fractional order satisfy the above integral equation (3):

$$
\left\{\begin{array}{l}
(-\triangle)^{\frac{\alpha}{2}} u=\frac{u^{\alpha^{*}(t)-1}}{|y|^{t}} \quad \text { in } \mathbb{R}^{n}  \tag{4}\\
u>0 \\
u \in H^{\frac{\alpha}{2}, 2}\left(\mathbb{R}^{n}\right)
\end{array}\right.
$$

where $\|u\|_{H^{\frac{\alpha}{2}, 2}}=\left\|\left(\left(1+|.|^{2}\right)^{\frac{\alpha}{4}} \hat{u}\right)^{\vee}\right\|_{L^{2}\left(\mathbb{R}^{n}\right)}$.
When $t=0$, (3) becomes

$$
\begin{equation*}
u(x)=\int_{\mathbb{R}^{n}} \frac{u^{\frac{n+\alpha}{n-\alpha}}(y)}{|x-y|^{n-\alpha}} d y \tag{5}
\end{equation*}
$$

The integral equation (5) arises as an Euler-Lagrange equation in the context of the Hardy-Littlewood-Sobolev inequality which has been extensively explored by Chen, Li and $\mathrm{Ou}[\mathrm{CLO}]$ and $\mathrm{Li}[\mathrm{L}]$ recently, where regularity and extremal functions of (5) are also obtained. (5) is actually equivalent to the following partial differential equation

$$
\begin{equation*}
(-\triangle)^{\frac{\alpha}{2}} u=u^{\frac{n+\alpha}{n-\alpha}} . \tag{6}
\end{equation*}
$$

When $\alpha=2$ and $0 \leq t<2$, the differential equation (4) and the integral equation (3) are closely related to the well-known Hardy-Sobolev type inequalities. Such inequalities of second order have been extensively studied by many authors (see [CW],[CC],[MFS], [BT], [CaL] and the references therein).

In fact, when $\alpha=2$ and $t=0$, (3) is closely related to the EulerLagrange equation of the extremal functions of the classical Sobolev inequality. Namely, (3) turns out to be the corresponding integral equation of the well-known Sobolev inequality

$$
\left(\int_{\mathbb{R}^{n}}|u|^{\frac{2 n}{n-2}} d y\right)^{\frac{n-2}{2 n}} \leq C\left(\int_{\mathbb{R}^{n}}|\nabla u(y)|^{2} d y\right)^{\frac{1}{2}}
$$

where the best constant $C$ and the extremal functions were identified by Aubin $[\mathrm{Au}]$ and Talenti $[\mathrm{T}]$.

Moreover, when $\alpha=2$ and $0<t<2$, (3) is closely related to the Euler-Lagrange equation of the extremal functions of the classical HardySobolev inequality which is a special case of Caffarelli-Kohn-Nirenberg inequality [CKN]. The classical Hardy-Sobolev inequality is stated as follows: There is a positive constant $C$ such that

$$
\begin{equation*}
\left(\int_{\mathbb{R}^{n}} \frac{|u|^{2^{*}(t)}}{|y|^{t}} d y\right)^{\frac{2}{2 *(t)}} \leq C \int_{\mathbb{R}^{n}}|\nabla u(y)|^{2} d y \tag{7}
\end{equation*}
$$

for any $u(x) \in D^{1,2}\left(\mathbb{R}^{n}\right)$. Furthermore, the best constant in (7) is achieved and the extremal function is identified by Lieb [Lie] up to dilation and translation by

$$
u(x)=\frac{1}{\left(1+|x|^{2-t}\right)^{\frac{n-2}{2-t}}} .
$$

We should note that the inequality (7) is a special case of the following more general Caffarelli-Kohn-Nirenberg inequality [CKN]: If $0 \leq a<\frac{n-2}{2}$, $a \leq b<a+1, p=\frac{2 n}{n-2+2(b-a)}$, then

$$
\begin{equation*}
\left(\int_{\mathbb{R}^{n}} \frac{|u(x)|^{p}}{\left.|x|\right|^{b p}} d x\right)^{\frac{2}{p}} \leq C_{a, b} \int_{\mathbb{R}^{n}}|x|^{-2 a}|\nabla u(x)|^{2} d x \tag{8}
\end{equation*}
$$

for any $u \in C_{0}^{\infty}\left(\mathbb{R}^{n}\right)$. Positive solutions of the associated Euler equation to (8) on an appropriate weighted Sobolev space turn out to be symmetric and they can be identified explicitly by solving an ODE and they are of the same form as in the case $a=0$. We refer the reader to [CW], [CC], etc.

In Section 1, we prove the following theorem by the moving plane method in integral forms.

Theorem 1. Assume $u(x) \in L^{\frac{2 n}{n-\alpha}}\left(\mathbb{R}^{n}\right)$ is a positive solution of (3), then $u(x)$ is radially symmetric and strictly decreasing about the origin.

In fact, we will derive the same result under the weaker condition that $u(x) \in L_{\text {loc }}^{\frac{2 n}{n-\alpha}}\left(\mathbb{R}^{n}\right)$ as indicated in Remark 2.1.

It is well known that the moving plane method was invented by the Soviet mathematician Alexandrov in the 1950s. Then it was further developed by Serrin [Se], Gidas, Ni and Nirenberg [GNN], Caffarelli, Gidas and Spruck
[CGS], Chen and Li [CL], Chang and Yang [CY] and many others. Recently, Chen, Li and Ou [CLO] applied the moving plane method to integral equations to obtain the symmetry, monotonicity and nonexistence properties of the solutions to the integral equations, see also Y. Li [L] using moving sphere method. Instead of the extensive use of maximum principle of differential equation, moving plane method in integral form explores various specific features of the integral equation itself. By virtue of Hardy-Littlewood-Sobolev inequality or Weighted-Hardy-Littlewood-Sobolev inequality and comparison of solution to the integral equation (3) and its reflection with the plane, the plane can be started to move from infinity. Furthermore the plane has to be moved to a critical point. Hence symmetry and monotonicity properties of solutions to (3) are consequently derived.

In Section 2, we study the regularity of extremal functions of the following integral equation

$$
\begin{equation*}
u(x)=\int_{\mathbb{R}^{n}} \frac{|u(y)|^{p} u(y)}{|y|^{t}|x-y|^{n-\alpha}} d y \tag{9}
\end{equation*}
$$

where $p>0$. In [CLO2] and [L], the authors consider the nonnegative solutions of the above integral equation in the case $t=0$ and $p=\frac{2 \alpha}{n-\alpha}$. They prove $u \in C^{\infty}\left(\mathbb{R}^{n}\right)$.

In this paper, we consider the symmetry and regularity of solutions to the integral equation (9) in the case $0<t<\alpha$. Thus, the second main result of our paper is as follows:
Theorem 2. If $u(x) \in L^{\frac{p n}{\alpha-t}}\left(\mathbb{R}^{n}\right)$ is the solution of (9), then $u(x) \in L^{\infty}\left(\mathbb{R}^{n}\right)$. Moreover $u(x) \in C^{[\alpha-t], \beta}\left(\mathbb{R}^{n}\right)$ for any $\beta<\alpha-t-[\alpha-t]$. In particular, $u(x)$ is $C^{\infty}$ in $\mathbb{R}^{n} \backslash\{0\}$, where $[\alpha-t]$ is the greatest integer function.

If $p=\alpha^{*}(t)-2$, then $\frac{p n}{\alpha-t}=\frac{2 n}{n-\alpha}$, which is exactly the critical Sobolev imbedding exponent of $H^{\frac{\alpha}{2}}, 2\left(\mathbb{R}^{n}\right)$. If $\alpha=2$ and $p$ is as above, our Theorem 2 provides a new proof of regularity of extremal function of Hardy-Sobolev inequality, since we prove it through the corresponding integral equation. See [MFS] for Hölder's regularity of solutions of (4) in case of $\alpha=2$. Moreover our Theorem 2 not only proves the regularity of extremal function of (4), but can also be applied to regularity for more general integral equations or corresponding partial differential equations. The method used here is called Regularity Lifting theorem based on contraction map theorem. The related lemma is presented in Section 2. It is a simple method to boost regularity of solutions. We refer the reader to [CLO2] for more details.

In Section 3, we will study the relations of (3) and (4).
Theorem 3. If $u(x)$ is a solution to (4), then $u(x)$ satisfies (3).
In [CLO], the authors prove the equivalence of (5) and (6), namely the special case of $t=0$. We will prove that (4) and (3) are actually equivalent in Section 3. Moreover, if $\alpha$ is an even number, we then give a new and relatively easy way to derive (3) from (4) by choosing an appropriate cut-off function.

Combining Theorems $\mathbf{1}$ and 3, we get the following
Corollary 1. Assume $u(x) \in L^{\frac{2 n}{n-\alpha}}\left(\mathbb{R}^{n}\right)$ is a positive solution of (4), then $u(x)$ is radially symmetric and strictly decreasing about the origin.

Throughout this paper, the positive constant $C$ is frequently used in the paper. It may differ from line to line, even within the same line and it has nothing to do with $u(x)$.

## 2 The proof of Theorem 1

For the convenience of the reader, we present the following Weighted Hardy-Littlewood-Sobolev inequality (see [JL]).

Lemma 2.1. Let $1<l, m<\infty, 0<\nu<n, \tau+\beta \geq 0, \frac{1}{l}+\frac{1}{m}+\frac{\nu+\beta+\tau}{n}=2$ and $1-\frac{1}{m}-\frac{\nu}{n} \leq \frac{\tau}{n}<1-\frac{1}{m}$. Then the weighted HLS inequality states

$$
\left|\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} \frac{f(x) g(y)}{|x|^{\tau}|x-y|^{\nu}|y|^{\beta}} d x d y\right| \leq C\|f\|_{L^{m}}\|g\|_{L^{l}} .
$$

The Weighted Hardy-Littlewood-Sobolev inequality can also be written in another form. Let $T g(x)=\int_{\mathbb{R}^{n}} \frac{g(y)}{\left.|x|^{\mid \tau}|x-y|^{\nu}| |\right|^{\mid}} d y$, then

$$
\begin{equation*}
\|T g(x)\|_{L^{\gamma}}=\sup _{\|f\|_{L^{m}=1}}<T g(x), f(x)>\leq C\|g\|_{L^{l}} \tag{10}
\end{equation*}
$$

where $\frac{1}{l}+\frac{\nu+\beta+\tau}{n}=1+\frac{1}{\gamma}, \frac{1}{m}+\frac{1}{\gamma}=1$.
In order to prove our theorems, we first introduce some notations. For any real number $\lambda$, define

$$
\begin{gathered}
\Sigma_{\lambda}=\left\{x=\left(x_{1}, x_{2}, \cdots, x_{n}\right), x_{1} \leq \lambda\right\}, \\
T_{\lambda}=\left\{x \mid x_{1}=\lambda\right\} .
\end{gathered}
$$

Let $x \in \Sigma_{\lambda}$ and $x_{\lambda}=\left(2 \lambda-x_{1}, x_{2}, \cdots, x_{n}\right)$. Moreover, define $u_{\lambda}(x)=u\left(x_{\lambda}\right)$.

Lemma 2.2. For any solution $u(x)$ of (3), we have

$$
\begin{equation*}
u(x)-u_{\lambda}(x)=\int_{\Sigma_{\lambda}}\left[\frac{1}{|x-y|^{n-\alpha}}-\frac{1}{\left|x_{\lambda}-y\right|^{n-\alpha}}\right]\left[\frac{u^{\alpha^{*}(t)-1}(y)}{|y|^{t}}-\frac{u_{\lambda}^{\alpha^{*}(t)-1}(y)}{\left|y_{\lambda}\right|^{t}}\right] d y \tag{11}
\end{equation*}
$$

Proof. Since $\left|x-y_{\lambda}\right|=\left|x_{\lambda}-y\right|$,

$$
\begin{aligned}
& u(x)=\int_{\Sigma_{\lambda}} \frac{u^{\alpha^{*}(t)-1}(y)}{|y|^{t}|x-y|^{n-\alpha}} d y+\int_{\Sigma_{\lambda}} \frac{u_{\lambda}^{\alpha^{*}(t)-1}(y)}{\left|y_{\lambda}\right|^{t}\left|x-y_{\lambda}\right|^{n-\alpha}} d y \\
& u\left(x_{\lambda}\right)=\int_{\Sigma_{\lambda}} \frac{u^{\alpha^{*}(t)-1}(y)}{|y|^{t}\left|x_{\lambda}-y\right|^{n-\alpha}} d y+\int_{\Sigma_{\lambda}} \frac{u_{\lambda}^{\alpha^{*}(t)-1}(y)}{\left|y_{\lambda}\right|^{t}|x-y|^{n-\alpha}} d y
\end{aligned}
$$

By considering $u(x)-u\left(x_{\lambda}\right)$ and making a simple calculation, the proof of the lemma is completed.

We now outline the ideas of the moving plane method in our proof. To prove Theorem 1, We compare the value of $u(x)$ with $u_{\lambda}(x)$ in $\Sigma_{\lambda}$. The proof consists of two steps. In step 1 , we show that for sufficiently negative $\lambda$,

$$
\begin{equation*}
u(x) \leq u_{\lambda}(x) \tag{12}
\end{equation*}
$$

Thus we can start to move the plane $T_{\lambda}$ along the $x_{1}$ direction continuously from near negative infinity to the right as long as (12) holds. In step 2 , We show that the plane can move to the limit case $x_{1}=0$, hence $u(x) \leq u_{0}(x)$ for $x \in \Sigma_{0}$. If we choose to move the plane from positive infinity to the left and carry on the same procedure as done in Steps 1 and 2, we can also prove that $u(x) \geq u_{0}(x)$ for $x \in \mathbb{R}^{n} \backslash \Sigma_{0}$. Therefore $u(x)$ is symmetric about the plane $T_{0}$. Since the direction of $x_{1}$ can be chosen arbitrarily, we deduce that $u(x)$ is symmetric and decreasing about the origin.

## Proof. of Theorem :

Step 1: We show that for sufficiently negative $\lambda$,

$$
\begin{equation*}
u(x) \leq u\left(x_{\lambda}\right), \quad \forall x \in \Sigma_{\lambda} . \tag{13}
\end{equation*}
$$

Define

$$
w_{\lambda}(x)=u(x)-u\left(x_{\lambda}\right)
$$

and

$$
\Sigma_{\lambda}^{-}=\left\{x \in \Sigma_{\lambda} \mid u(x)>u\left(x_{\lambda}\right)\right\} .
$$

From Lemma (2.2), we have

$$
\begin{aligned}
u(x)-u\left(x_{\lambda}\right)= & \int_{\Sigma_{\lambda} \mid \Sigma_{\lambda}^{-}}\left(\frac{1}{|x-y|^{n-\alpha}}-\frac{1}{\left|x_{\lambda}-y\right|^{n-\alpha}}\right)\left[\frac{u^{\alpha^{*}(t)-1}}{|y|^{t}}-\frac{u_{\lambda}^{\alpha^{*}(t)-1}}{\left|y_{\lambda}\right|^{t}}\right] d y \\
& +\int_{\Sigma_{\lambda}^{-}}\left(\frac{1}{|x-y|^{n-\alpha}}-\frac{1}{\left|x_{\lambda}-y\right|^{n-\alpha}}\right)\left[\frac{u^{\alpha^{*}(t)-1}}{|y|^{t}}-\frac{u_{\lambda}^{\alpha^{*}(t)-1}}{\left|y_{\lambda}\right|^{t}}\right] d y
\end{aligned}
$$

Since $|x-y|<\left|x_{\lambda}-y\right|$ and $|y|>\left|y_{\lambda}\right|$ in $\Sigma_{\lambda}$, by the definition of $\Sigma_{\lambda}^{-}$,

$$
u(x)-u\left(x_{\lambda}\right) \leq \int_{\Sigma_{\lambda}^{-}}\left(\frac{1}{|x-y|^{n-\alpha}}-\frac{1}{\left|x_{\lambda}-y\right|^{n-\alpha}}\right)\left[\frac{u^{\alpha^{*}(t)-1}-u_{\lambda}^{\alpha^{*}(t)-1}}{|y|^{\lambda}}\right] d y .
$$

Moreover, from the Mean Value Theorem,

$$
\begin{equation*}
u(x)-u\left(x_{\lambda}\right) \leq C \int_{\Sigma_{\lambda}^{-}} \frac{1}{|x-y|^{n-\alpha}} \frac{1}{|y|^{t}} u^{\alpha^{*}(t)-2}\left(u-u_{\lambda}\right) d y . \tag{14}
\end{equation*}
$$

By virtue of the Weighted-Hardy-Littlewood-Sobolev inequality, i.e. Lemma 2.1 (see also (10)) in the case of $\tau=0$ in (14), for any $q>\frac{n}{n-\alpha}$ (without loss of generality, let $q=\frac{2 n}{n-\alpha}$ ), we have

$$
\left\|w_{\lambda}\right\|_{L^{q}\left(\Sigma_{\lambda}^{-}\right)} \leq C\left\|u^{\alpha^{*}(t)-2} w_{\lambda}\right\|_{L^{\frac{n q}{\alpha q+n-q t}\left(\Sigma_{\lambda}^{-}\right)}} .
$$

Then from Hölder's inequality, we get

$$
\left\|w_{\lambda}\right\|_{L^{q}\left(\Sigma_{\lambda}^{-}\right)} \leq C\|u\|_{L^{\frac{2 n}{n-\alpha}\left(\Sigma_{\lambda}^{-}\right)}}^{\frac{2(\alpha-t)}{n-\alpha}}\left\|w_{\lambda}\right\|_{L^{q}\left(\Sigma_{\lambda}^{-}\right)} .
$$

Since $u \in L^{\frac{2 n}{n-\alpha}}\left(\mathbb{R}^{n}\right)$, we can choose sufficiently negative $\lambda$ such that

$$
C\|u\|_{L^{\frac{2 n}{n-\alpha}\left(\Sigma_{\lambda}^{-}\right)}}^{\frac{2(\alpha-t)}{n-\alpha}} \leq \frac{1}{2} .
$$

Therefore

$$
\left\|w_{\lambda}\right\|_{L^{q}\left(\Sigma_{\lambda}^{-}\right)} \leq \frac{1}{2}\left\|w_{\lambda}\right\|_{L^{q}\left(\Sigma_{\lambda}^{-}\right)} .
$$

This implies $\Sigma_{\lambda}^{-}$must be of measure zero. Hence (13) is verified.
Step 2: Assuming that the plane can move to the critical point $\lambda_{0}<0$. If there exists some point $x_{0}$ in $\Sigma_{\lambda_{0}}$ such that $u\left(x_{0}\right)=u_{\lambda_{0}}\left(x_{0}\right)$, from Lemma (2.2), we have
$0=u\left(x_{0}\right)-u_{\lambda_{0}}\left(x_{0}\right)=\int_{\Sigma_{\lambda_{0}}}\left[\frac{1}{\left|x_{0}-y\right|^{n-\alpha}}-\frac{1}{\left|x_{\lambda_{0}}-y\right|^{n-\alpha}}\right]\left[\frac{u^{\alpha^{*}(t)-1}}{|y|^{t}}-\frac{u_{\lambda_{0}}^{\alpha^{*}(t)-1}}{\left|y_{\lambda_{0}}\right|^{t}}\right] d y$.
Let $x_{\lambda_{0}}=\left(x_{0}\right)_{\lambda_{0}}$. Since $|y|>\left|y_{\lambda_{0}}\right|$ in $\Sigma_{\lambda_{0}}$,

$$
\frac{u(y)^{\alpha^{*}(t)-1}}{|y|^{t}}<\frac{u_{\lambda_{0}}(y)^{\alpha^{*}(t)-1}}{\left|y_{\lambda_{0}}\right|^{t}} \quad \text { in } \Sigma_{\lambda_{0}}
$$

Moreover $\left|x_{0}-y\right|<\left|x_{\lambda_{0}}-y\right|$ in $\Sigma_{\lambda_{0}}$, we infer that

$$
u(x) \equiv u_{\lambda_{0}}(x) \equiv 0, \quad \forall x \in \Sigma_{\lambda_{0}} .
$$

This also implies that $u(x) \equiv 0$. But it is impossible. Hence

$$
u(x)<u_{\lambda_{0}}(x), \quad \forall x \in \Sigma_{\lambda_{0}} .
$$

We Claim that

$$
\begin{equation*}
\lambda_{0}=\sup \left\{\lambda \mid u(x)-u_{\lambda}(x) \leq 0, \quad \forall x \in \Sigma_{\lambda}\right\}=0 . \tag{15}
\end{equation*}
$$

If not, i.e. $\lambda_{0}<0$, we prove that the plane can be moved to the right a little bit further. Since $u \in L^{\frac{2 n}{n-\alpha}}\left(\mathbb{R}^{n}\right)$, for any small $\epsilon$, there exists a large enough ball $\mathbb{B}_{R}(0)$ such that

$$
\int_{\mathbb{R}^{n} \backslash \mathbb{B}_{R}(0)} u^{\frac{2 n}{n-\alpha}} d x<\epsilon
$$

By virtue of Lusin's theorem, for any $\delta$, there exists a closed set $F_{\delta}$ such that $\left.w_{\lambda_{0}}\right|_{F_{\delta}}$ is continuous, with $F_{\delta} \subset \mathbb{B}_{R}(0) \bigcap \Sigma_{\lambda_{0}}=E$ and $m\left(E-F_{\delta}\right)<\delta$. As $w_{\lambda_{0}}(x)<0$ in the interior of $\Sigma_{\lambda_{0}}, w_{\lambda_{0}}(x)<0$ in $F_{\delta}$.

Choosing $\epsilon_{1}$ sufficiently small, for any $\lambda \in\left[\lambda_{0}, \lambda_{0}+\epsilon_{1}\right)$, it holds that

$$
w_{\lambda}<0, \quad \forall x \in F_{\delta} .
$$

It follows that, for such $\lambda$,

$$
\Sigma_{\lambda}^{-} \subset M:=\left(\mathbb{R}^{n} \backslash \mathbb{B}_{R}(0)\right) \cup\left(E \backslash F_{\delta}\right) \cup\left[\left(\Sigma_{\lambda} \backslash \Sigma_{\lambda_{0}}^{-}\right) \cap \mathbb{B}_{R}(0)\right] .
$$

Choosing $\epsilon, \delta$ and $\epsilon_{1}$ so small and from the absolute continuity of integration, we have

$$
C\|u\|_{L^{\frac{2 n}{n-\alpha}}(M)}^{\frac{2(\alpha-t)}{n-\alpha}} \leq \frac{1}{2} .
$$

Finally

$$
\left\|w_{\lambda}\right\|_{L^{q}\left(\Sigma_{\lambda}^{-}\right)} \leq C\|u\|_{L^{\frac{2 n}{n-\alpha}\left(\Sigma_{\lambda}^{-}\right)}}^{\frac{2(\alpha-t)}{n-\alpha}}\left\|w_{\lambda}\right\|_{L^{q}\left(\Sigma_{\lambda}^{-}\right)}<\frac{1}{2}\left\|w_{\lambda}\right\|_{L^{q}\left(\Sigma_{\lambda}^{-}\right)} .
$$

This again implies $\Sigma_{\lambda}^{-}$must be empty. It contradicts with the assumption that $\lambda_{0}<0$. Therefore, (15) is verified.

On the other hand, we can also move the plane from positive infinity to zero by the similar procedure, hence $u(x)$ is symmetric and monotonic with respect to $x_{1}=0$. Moreover, since the $x_{1}$ direction can be chosen arbitrarily, $u(x)$ is radial symmetric and strictly monotonic with respect to the origin. We thus have completed the proof of Theorem 1.

Remark 2.1. Since (3) is invariant under the Kelvin transform, we can also prove that $u(x)$ is symmetric with respect to the origin under a weaker assumption that $u(x) \in L_{\text {loc }}^{\frac{2 n}{n-\alpha}}\left(\mathbb{R}^{n}\right)$. Assume

$$
v(x)=\frac{1}{|x|^{n-\alpha}} u\left(\frac{x}{|x|^{2}}\right),
$$

then $v(x)$ satisfies (3) and $v(x) \in L_{o c}^{\frac{2 n}{n-\alpha}}(\Omega)$, where $\Omega$ is any domain with positive distance from the origin. Carrying out the first and second steps for $v(x)$ as we did before, we conclude that $v(x)$ is symmetric and monotonic with respect to the origin. This implies that $u(x)$ is symmetric with respect to the origin.

## 3 The proof of Theorem 2

In this section, we prove the regularity for functions satisfying (9) by the contraction map. We present the regularity lift lemma below. See also ([CL1]).

Let Z be a given vector space, $\|\cdot\|_{X}$ and $\|\cdot\|_{Y}$ be two norms on Z . Define a new norm $\|\cdot\|_{Z}$ by

$$
\|\cdot\|_{Z}=\sqrt[p]{\|\cdot\|_{X}^{p}+\|\cdot\|_{Y}^{p}}
$$

For simplicity, we assume that $Z$ is complete with respect to the norm $\|\cdot\|_{Z}$. Let $X$ and $Y$ be the completion of $Z$ under $\|\cdot\|_{X}$ and $\|.\|_{Y}$, respectively. Here one can choose $p, 1 \leq p \leq \infty$, according to what one needs. It's easy to see that $Z=X \bigcap Y$.

Lemma 3.1. (Regularity Lifting) Let $T$ be a contraction map from $X$ into itself and from $Y$ into itself. Assume that $f \in X$ and that there exists a function $g \in Z$ such that $f=T f+g$, then $f$ also belongs to $Z$.

## Proof. of Theorem 2:

We define a linear operator

$$
T_{u} w(x)=\int_{\mathbb{R}^{n}} \frac{|u(y)|^{p} w}{|y|^{t}|x-y|^{n-\alpha}} d y
$$

For any positive real number $a$, define

$$
\begin{cases}u_{a}(x)=u(x), & \text { if }|u(x)|>a \text { or }|x|>a,  \tag{16}\\ u_{a}(x)=0, & \text { otherwise } .\end{cases}
$$

Let $u_{b}(x)=u(x)-u_{a}(x)$. Since $u$ satisfies (9),

$$
\begin{equation*}
u_{a}(x)=\int_{\mathbb{R}^{n}} \frac{\left|u_{a}\right|^{p} u_{a}}{|y|^{t}|x-y|^{n-\alpha}} d y+I(x) \tag{17}
\end{equation*}
$$

where $I(x)=\int_{\mathbb{R}^{n}} \frac{\left|u_{b}\right|^{p} u_{b}}{|y|^{t}|x-y|^{n-\alpha}} d y-u_{b}(x)$.
As to $I(x)$, for $s>\frac{n}{n-\alpha}$, we Claim that

$$
I(x) \in L^{\infty}\left(\mathbb{R}^{n}\right) \bigcap L^{s}\left(\mathbb{R}^{n}\right)
$$

Obviously, $u_{b}(x) \in L^{\infty}\left(\mathbb{R}^{n}\right) \bigcap L^{s}\left(\mathbb{R}^{n}\right)$.
Thus, we only need to prove $A(x):=\int_{\mathbb{R}^{n}} \frac{\left|u_{b}\right|^{p} u_{b}}{|y|^{t}|x-y|^{n-\alpha}} d y \in L^{\infty}\left(\mathbb{R}^{n}\right) \bigcap L^{s}\left(\mathbb{R}^{n}\right)$.
By the definition of $u_{b}(x)$, for $\forall x \in \mathbb{R}^{n}$,

$$
|A(x)| \leq C \int_{|y| \leq a} \frac{1}{|y|^{t}|x-y|^{n-\alpha}} d y
$$

If $x \in \mathbb{R}^{n} \backslash \mathbb{B}_{2 a}(0),|x-y| \geq|y|$, then

$$
\int_{|y| \leq a} \frac{1}{|y|^{t}|x-y|^{n-\alpha}} d y \leq \int_{|y| \leq a} \frac{1}{|y|^{n-\alpha+t}} d y<\infty
$$

If $x \in \mathbb{B}_{2 a}(0)$,

$$
\int_{|y| \leq a} \frac{1}{|y|^{t}|x-y|^{n-\alpha}} d y \leq \int_{|y| \leq a} \frac{1}{|y|^{n-\alpha+t}} d y+\int_{|x-y| \leq 3 a} \frac{1}{|x-y|^{n-\alpha+t}} d y<\infty
$$

hence $A(x) \in L^{\infty}\left(\mathbb{R}^{n}\right)$. Using Weighted Hardy-Littlewood-Sobolev inequality,

$$
\|A(x)\|_{L^{s}} \leq\left\|\left|\left|u_{b}\right|^{p} u_{b} \|_{L^{\frac{n s}{\alpha s+n-s t}\left(\mathbb{B}_{a}\right)}}<\infty\right.\right.
$$

then $A(x) \in L^{s}\left(\mathbb{R}^{n}\right)$. Therefore, we have proved the claim.
Next for any $q>\frac{n}{n-\alpha}$, we show that $T_{u_{a}} w$ is a contraction map. Applying the Weighted Hardy-Littlewood-Sobolev inequality and, then Hölder's inequality, we get

$$
\begin{equation*}
\left\|T_{u_{a}} w\right\|_{L^{q}} \leq\left\|\left|u_{a}\right|^{p} w\right\|_{L^{\frac{n q}{\alpha q+n-q t}}} \leq\left\|\left|u_{a}\right|^{p}\right\|_{L^{\frac{n}{\alpha-t}}}\|w\|_{L^{q}} . \tag{18}
\end{equation*}
$$

Since $u(x) \in L^{\frac{n p}{\alpha-t}}$, for sufficiently large $a$, we deduce

$$
\begin{equation*}
\left\|T_{u_{a}} w(x)\right\|_{L^{q}} \leq \frac{1}{2}\|w\|_{L^{q}} \tag{19}
\end{equation*}
$$

which shows that $T_{u_{a}} w$ is a contraction map. Applying (19) to both the case of $q=\frac{n p}{\alpha-t}$ and the case of any $q_{0}>\frac{n}{n-\alpha}$, and by the contraction map lemma (i.e. Lemma 3.1), we can conclude that $u_{a} \in L^{q} \bigcap L^{q_{0}}$.

Furthermore, we Claim that $u \in L^{\infty}\left(\mathbb{R}^{n}\right)$. Since $u(x)=u_{a}(x)+u_{b}(x)$ and $u_{b}(x) \in L^{\infty}\left(\mathbb{R}^{n}\right)$, we only need to verify $u_{a}(x) \in L^{\infty}\left(\mathbb{R}^{n}\right)$. Due to (17) and $I(x) \in L^{\infty}\left(\mathbb{R}^{n}\right)$, it is equivalent to verify that

$$
B(x):=\int_{\mathbb{R}^{n}} \frac{\left|u_{a}\right|^{p} u_{a}}{|y|^{t}|x-y|^{n-\alpha}} d y \in L^{\infty}\left(\mathbb{R}^{n}\right)
$$

Note

$$
\begin{equation*}
B(x) \leq \int_{\mathbb{B}_{a}(0)} \frac{\left|u_{a}\right|^{p+1}}{|y|^{t}|x-y|^{n-\alpha}} d y+\int_{\mathbb{R}^{n} \backslash \mathbb{B}_{a}(0)} \frac{\left|u_{a}\right|^{p+1}}{|y|^{t}|x-y|^{n-\alpha}} d y . \tag{20}
\end{equation*}
$$

If $x \in \mathbb{R}^{n} \backslash \mathbb{B}_{2 a}(0)$, then $|x-y|>|y|$ and

$$
\begin{equation*}
\int_{\mathbb{B}_{a}(0)} \frac{\left|u_{a}\right|^{p+1}}{|y|^{t}|x-y|^{n-\alpha}} d y \leq \int_{\mathbb{B}_{a}(0)} \frac{\left|u_{a}\right|^{p+1}}{|y|^{n-\alpha+t}} d y<\infty \tag{21}
\end{equation*}
$$

by Hölder's inequality with the help of $u_{a} \in L^{q} \bigcap L^{q_{0}}$. If $x \in \mathbb{B}_{2 a}(0)$, similarly

$$
\begin{equation*}
\int_{\mathbb{B}_{a}(0)} \frac{\left|u_{a}\right|^{p+1}}{|y|^{t}|x-y|^{n-\alpha}} d y \leq \int_{\mathbb{B}_{a}(0)} \frac{\left|u_{a}\right|^{p+1}}{|y|^{n-\alpha+t}} d y+\int_{\mathbb{B}_{3 a}(x)} \frac{\left|u_{a}\right|^{p+1}}{|x-y|^{n-\alpha+t}} d y<\infty \tag{22}
\end{equation*}
$$

by Hölder's inequality and the property that $u_{a} \in L^{q} \bigcap L^{q_{0}}$.
Combining (21) and (22), for any $x \in \mathbb{R}^{n}$, we derive that

$$
\begin{equation*}
\int_{\mathbb{B}_{a}(0)} \frac{\left|u_{a}\right|^{p+1}}{|y|^{\mid t}|x-y|^{n-\alpha}} d y<\infty \tag{23}
\end{equation*}
$$

Next, for $\forall x \in \mathbb{R}^{n}$,

$$
\begin{align*}
\int_{\mathbb{R}^{n} \backslash \mathbb{B}_{a}(0)} \frac{\left|u_{a}\right|^{p+1}}{\left.|y|\right|^{\mid}|x-y|^{n-\alpha}} d y \leq & \frac{1}{a^{t}} \int_{\mathbb{B}_{a}(x)} \frac{\left|u_{a}\right|^{p+1}}{|x-y|^{n-\alpha}} d y \\
& +\int_{\left(R^{n} \backslash \mathbb{B}_{a}(0)\right) \cap\left(\mathbb{R}^{n} \backslash B_{a}(x)\right)} \frac{\left|u_{a}\right|^{p+1}}{|y|^{t}|x-y|^{n-\alpha}} d y \tag{24}
\end{align*}
$$

By virtue of Hölder's inequality, it is easy to see that

$$
\begin{equation*}
\frac{1}{a^{t}} \int_{\mathbb{B}_{a}(x)} \frac{\left|u_{a}\right|^{p+1}}{|x-y|^{n-\alpha}} d y<\infty \tag{25}
\end{equation*}
$$

Since

$$
\begin{aligned}
\int_{\left(R^{n} \backslash \mathbb{B}_{a}(0)\right) \cap\left(\mathbb{R}^{n} \backslash B_{a}(x)\right)} \frac{\left|u_{a}\right|^{p+1}}{|y|^{t}|x-y|^{n-\alpha}} d y \leq & \int_{\mathbb{R}^{n} \backslash \mathbb{B}_{a}(x)} \frac{\left|u_{a}\right|^{p+1}}{|x-y|^{n-\alpha+t}} d y \\
& +\int_{\mathbb{R}^{n} \backslash \mathbb{B}_{a}(0)} \frac{\left|u_{a}\right|^{p+1}}{|y|^{n-\alpha+t}} d y
\end{aligned}
$$

we can also prove that

$$
\begin{equation*}
\int_{\left(R^{n} \backslash \mathbb{B}_{a}(0)\right) \cap\left(\mathbb{R}^{n} \backslash B_{a}(x)\right)} \frac{\left|u_{a}\right|^{p+1}}{|y|^{t}|x-y|^{n-\alpha}} d y<\infty \tag{26}
\end{equation*}
$$

by Hölder's inequality and the estimate $u_{a} \in L^{q} \bigcap L^{q_{0}}$.
Through (24), (25) and (26), we deduce that

$$
\begin{equation*}
\int_{\mathbb{R}^{n} \backslash \mathbb{B}_{a}(0)} \frac{\left|u_{a}\right|^{p+1}}{|y|^{t}|x-y|^{n-\alpha}} d y<\infty \tag{27}
\end{equation*}
$$

Therefore, from (20), (23) and (27), we have $B(x) \in L^{\infty}\left(\mathbb{R}^{n}\right)$. Hence the claim that $u(x) \in L^{\infty}\left(\mathbb{R}^{n}\right)$ is verified.

To show the higher regularity, we first show that $u(x) \in C^{\infty}\left(\mathbb{R}^{n} \backslash\{0\}\right)$.
For any $x \in \mathbb{R}^{n} \backslash\{0\}$, we choose a ball $\mathbb{B}_{3 r}(x)$ with radius $3 r$ such that $0 \notin \overline{\mathbb{B}}_{3 r}(x)$, then

$$
\begin{equation*}
u(x)=\int_{\mathbb{R}^{n} \backslash \mathbb{B}_{3 r}(x)} \frac{|u|^{p} u}{|y|^{t}|x-y|^{n-\alpha}} d y+\int_{\mathbb{B}_{3 r}(x)} \frac{|u|^{p} u}{|y|^{t}|x-y|^{n-\alpha}} d y . \tag{28}
\end{equation*}
$$

We show that $R(x):=\int_{\mathbb{R}^{n} \backslash \mathbb{B}_{3 r}(x)} \frac{\left.| | y\right|^{p} u}{|y-x|^{n-\alpha}} d y \in C^{\infty}\left(\mathbb{R}^{n} \backslash\{0\}\right)$.
Let $F(x, y):=\frac{|u(y)|^{p u(y)}}{|y|^{\dagger}|x-y|^{n-\alpha}} \chi_{\mathbb{R}^{n} \backslash \mathbb{B}_{3 r}(x)}$.
For fixed $x$, if $h$ is small enough, considering

$$
\begin{align*}
&\left|\frac{F\left(x+h e_{i}, y\right)-F(x, y)}{h}\right|= \frac{\frac{|u(y)|^{p} u(y)}{|y|^{t}}\left(\left.\frac{\left.\chi_{\mathbb{R}^{n} \backslash \mathbb{B}_{3}\left(x+h e_{i}\right)}^{\left|x+h e_{i}-y\right|^{n-\alpha}}-\frac{\chi_{\mathbb{R}^{n} \backslash \mathbb{B}_{3}(x)}}{|x-y|^{n-\alpha}}\right)}{h} \right\rvert\,\right.}{\leq} C C \frac{|u(y)|^{p+1} \chi_{\mathbb{R}^{n} \backslash \mathbb{B}_{3 r}\left(x+\theta e_{i}\right)}}{|y|^{t}\left|x+\theta h e_{i}-y\right|^{n-\alpha+1}} \\
& \leq C \frac{|u(y)|^{p+1}}{|y|^{t}\left|x+\theta h e_{i}-y\right|^{n-\alpha+1}} \chi_{\mathbb{R}^{n} \backslash \mathbb{B}_{2 r}(x)} \\
& \leq C \quad\left\{\frac{|u(y)|^{p+1}}{|y|^{t} r^{n-\alpha+1}} \chi_{\mathbb{B}_{\epsilon}(0)}\right. \\
&\left.+\frac{|u(y)|^{p+1}}{|y|^{\mid t}|x-y|^{n-\alpha+1}} \chi_{\left.\mathbb{R}^{n} \backslash\left(\mathbb{B}_{r}(x) \cup \mathbb{B}_{\epsilon}(0)\right)\right\}}\right\},
\end{align*}
$$

where $e_{i}=\{0, \cdots, 1, \cdots, 0\}$ is the $i$ th unit vector, $0<\theta<1$ and $\epsilon$ is so small that $\mathbb{B}_{\epsilon}(0) \cap \mathbb{B}_{3 r}(x)=\varnothing$. Since $u \in L^{\infty}\left(\mathbb{R}^{n}\right)$, it is easy to verify

$$
\begin{equation*}
\int_{\mathbb{B}_{\epsilon}(0)} \frac{|u|^{p+1}}{|y|^{t} r^{n-\alpha+1}} d y<\infty \tag{30}
\end{equation*}
$$

for fixed $r$.
For such fixed $r$ and $\epsilon$, let

$$
\begin{aligned}
\left.\int_{\mathbb{R}^{n} \backslash\left(\mathbb{B}_{r}(x) \cup \mathbb{B}_{\epsilon}(0)\right)} \frac{|u|^{p+1}}{} d y\right|^{|t| x-\left.y\right|^{n-\alpha+1}} d y & \int_{\mathbb{R}^{n} \backslash \mathbb{B}_{r}(x)} \frac{|u|^{p+1}}{} \begin{aligned}
|x-y|^{n-\alpha+1+t}
\end{aligned} y \\
& +\int_{\mathbb{R}^{n} \backslash \mathbb{B}_{\epsilon}(0)} \frac{|u|^{p+1}}{|y|^{n-\alpha+1+t}} d y
\end{aligned}
$$

Since $u \in L^{q}$ for any $q>\frac{n p}{\alpha-t}$, using Hölder's inequality,

$$
\begin{gathered}
\int_{\mathbb{R}^{n} \backslash \mathbb{B}_{r}(x)} \frac{|u|^{p+1}}{|x-y|^{n-\alpha+1+t}} d y<\infty \\
\int_{\mathbb{R}^{n} \backslash \mathbb{B}_{\epsilon}(0)} \frac{|u|^{p+1}}{|y|^{n-\alpha+1+t}} d y<\infty
\end{gathered}
$$

then

$$
\begin{equation*}
\int_{\mathbb{R}^{n} \backslash\left(\mathbb{B}_{r}(x) \cup \mathbb{B}_{\epsilon}(0)\right)} \frac{|u|^{p+1}}{|y|^{t}|x-y|^{n-\alpha+1}} d y<\infty . \tag{31}
\end{equation*}
$$

With (29), (30), (31) and the Lebesgue dominated convergence theorem, $R(x) \in C^{1}\left(\mathbb{R}^{n} \backslash\{0\}\right)$. Continuing this process,

$$
\begin{equation*}
R(x) \in C^{\infty}\left(\mathbb{R}^{n} \backslash\{0\}\right) \tag{32}
\end{equation*}
$$

By standard singular integral estimates (chapter 10 in [LL]),

$$
\begin{equation*}
\int_{\mathbb{B}_{2 r}(x)} \frac{|u|^{p} u}{|y|^{t}|x-y|^{n-\alpha}} d y \in C^{\beta_{1}}\left(\mathbb{R}^{n} \backslash\{0\}\right) \tag{33}
\end{equation*}
$$

for any $\beta_{1}<\alpha$. Combining (28), (32) and (33), $u(x) \in C^{\beta_{1}}\left(\mathbb{R}^{n} \backslash\{0\}\right)$. By the bootstrap technique, we can prove that $u(x) \in C^{\infty}\left(\mathbb{R}^{n} \backslash\{0\}\right)$.

The difficulty of regularity occurs around the origin. We note that

$$
\begin{aligned}
u(x)-u(0)= & \int_{\mathbb{R}^{n} \backslash \mathbb{B}_{2 r}(0)} \frac{|u|^{p} u}{|y|^{t}}\left[\frac{1}{|x-y|^{n-\alpha}}-\frac{1}{|y|^{n-\alpha}}\right] d y \\
& \left.+\int_{B_{2 r}(0)} \frac{\left.|u|^{p} u\right|^{t}}{|y|} \frac{1}{|x-y|^{n-\alpha}}-\frac{1}{|y|^{n-\alpha}}\right] d y
\end{aligned}
$$

If $\alpha-t \leq 1,0 \in D$ and the domain $D \subset \mathbb{B}_{r}(0)$, we show that $u \in C^{0, \beta}(D)$ for any $\beta<\alpha-t$. Indeed, from the following property

$$
\left||x-z|^{-c}-|y-z|^{-c}\right| \leq c|x-y|^{b}\left(|x-z|^{-c-b}+|y-z|^{-c-b}\right),
$$

where $c>0$ and $0<b<1$ ( see also chapter 10 in [LL]),

$$
\begin{aligned}
\sup _{x \in D} \frac{|u(x)-u(0)|}{|x|^{\beta}} \leq & \operatorname{Csup}_{x \in D} \int_{\mathbb{R}^{n} \backslash \mathbb{B}_{2 r}(0)} \frac{|u|^{p+1}}{|y|^{t}|x-y|^{n-\alpha+\beta}} d y \\
& +C \sup _{x \in D} \int_{\mathbb{B}_{2 r}(0)} \frac{|u|^{p+1}}{|y|^{t}|x-y|^{n-\alpha+\beta}} d y .
\end{aligned}
$$

With the help of Hölder's inequality as in (27), we have

$$
\begin{equation*}
\sup _{x \in D} \int_{\mathbb{R}^{n} \backslash \mathbb{B}_{2 r}(0)} \frac{|u|^{p+1}}{|y|^{t}|x-y|^{n-\alpha+\beta}} d y<\infty . \tag{34}
\end{equation*}
$$

From Hölder's inequality again and the property $u \in L^{\infty}\left(\mathbb{R}^{n}\right)$, we show

$$
\begin{equation*}
\sup _{x \in D} \int_{\mathbb{B}_{2 r}(0)} \frac{|u|^{p+1}}{|y|^{\mid t}|x-y|^{n-\alpha+\beta}} d y<\infty \tag{35}
\end{equation*}
$$

for any $\beta<\alpha-t$. Therefore, (34) and (35) imply that $u \in C^{0, \beta}\left(\mathbb{R}^{n}\right)$.
If $1<\alpha-t<2$, similarly we can prove $u(x) \in C^{1, \beta}(D)$ for $\beta<\alpha-t$, then $u(x) \in C^{1, \beta}\left(\mathbb{R}^{n}\right)$. For more general $0<t<\alpha$, we conclude that $u \in$ $C^{[\alpha-t], \beta}\left(\mathbb{R}^{n}\right)$ for any $\beta<\alpha-t-[\alpha-t]$. Hence, the proof of Theorem $\mathbf{2}$ is complete.

## 4 The proof of Theorem 3

## Proof. of Theorem 3:

The proof follows from the properties of the Riesz potential and the Fourier transform of the Riesz potential and is quite similar to that in [CLO]. For the completeness and the convenience of the reader, we include a proof here.

Let $\phi \in C_{0}^{\infty}\left(\mathbb{R}^{n}\right)$ and $\psi(x)=\int_{\mathbb{R}^{n}} \frac{\phi(y)}{|x-y|^{n-\alpha}} d y$. Then $(-\Delta)^{\frac{\alpha}{2}} \psi=\phi$. Then $\psi \in H^{\alpha}\left(\mathbb{R}^{n}\right)$. So if $u$ is a solution to the differential equation, then

$$
\int_{\mathbb{R}^{n}}(-\Delta)^{\frac{\alpha}{4}} u(-\Delta)^{\frac{\alpha}{4}} \psi d x=\int_{\mathbb{R}^{n}} \frac{u^{\alpha^{*}(t)}(y)}{|y|^{t}} \psi(y) d y .
$$

This implies

$$
\int_{\mathbb{R}^{n}} u(x)(-\Delta)^{\frac{\alpha}{2}} \psi(x) d x=\int_{\mathbb{R}^{n}}\left(\int_{\mathbb{R}^{n}} \frac{u^{\alpha^{*}(t)}(y)}{|y|^{t}} \frac{1}{|x-y|^{n-\alpha}} d y\right) \phi(x) d x
$$

for all $\phi \in C_{0}^{\infty}\left(\mathbb{R}^{n}\right)$. Therefore, $u(x)=\int_{\mathbb{R}^{n}} \frac{u^{\alpha^{*}(t)}(y)}{|y|^{t}} \frac{1}{|x-y|^{n-\alpha}} d y$, namely, the integral equation holds.

On the other hand, if the integral equation (3) i.e. $u(x)=\int_{\mathbb{R}^{n}} \frac{u^{\alpha^{*}(t)}(y)}{|y|^{t}} \frac{1}{|x-y|^{n-\alpha}} d y$ holds, then by taking Fourier transform on both sides we get

$$
\hat{u}(\xi)=c_{n}|\xi|^{-\alpha}\left(\frac{\widehat{u^{*}(t)}(y)}{|y|^{t}}\right)(\xi) .
$$

This implies that

$$
|\xi|^{\alpha} \hat{u}(\xi)=c_{n}\left(\frac{\widehat{u^{*}(t)}(y)}{|y|^{t}}\right)(\xi)
$$

Thus for any $\phi \in C_{0}^{\infty}\left(\mathbb{R}^{n}\right)$ we have

$$
\begin{gathered}
\int_{\mathbb{R}^{n}}(-\Delta)^{\frac{\alpha}{2}} u \phi=\int_{\mathbb{R}^{n}}(-\Delta)^{\frac{\alpha}{4}} u(-\Delta)^{\frac{\alpha}{4}} \phi \\
=c_{n} \int_{\mathbb{R}^{n}}|\xi|^{\alpha} \hat{u}(\xi) \hat{\phi}(\xi) d \xi=c_{n} \int_{\mathbb{R}^{n}}\left(\frac{u^{\hat{\alpha^{*}(t)}(y)}}{|y|^{t}}\right)(\xi) \hat{\phi}(\xi) d \xi \\
=c_{n} \int_{\mathbb{R}^{n}} \frac{u^{\alpha^{*}(t)}(y)}{|y|^{t}} \phi(y) d y .
\end{gathered}
$$

Therefore,

$$
(-\Delta)^{\frac{\alpha}{2}} u=\frac{u^{\alpha^{*}(t)}(y)}{|y|^{t}}
$$

namely $u$ satisfies (4).

We conclude this section by giving another proof of the fact that (4) implies (3) in the case of $\alpha=2 m$, where $m$ is a positive integer.

Proof. We argue as follows. By the regularity theorem in [ADN], $u \in$ $W_{\text {loc }}^{2 m, s}\left(\mathbb{R}^{n}\right)$ for some $1<s<\frac{2 n}{n+2 m}$. For any $x \in \mathbb{R}^{n}$, we multiply both sides of (4) by $\frac{1}{|x-y|^{n-2 m}} \psi(x-y)$. The cut-off function $\psi(x-y)=\eta\left(\frac{|x-y|}{R}\right)$. When
$0<r<1, \eta(r)=1$, while $\eta(r)=0$ when $r>2$. Moreover $0<\eta^{(i)}(r)<2$ in $(0,2)$ for $i=1, \cdots, 2 m$. Then

$$
\int_{\mathbb{R}^{n}}(-\triangle)^{m} u \frac{\psi(x-y)}{|x-y|^{n-2 m}} d y=\int_{\mathbb{R}^{n}} u^{(2 m)^{*}(t)-1} \frac{\psi(x-y)}{|y|^{t}|x-y|^{n-2 m}} d y .
$$

Using integration by parts several times, we have

$$
\begin{aligned}
& \int_{\mathbb{R}^{n}} u(-\triangle)^{m}\left(\frac{1}{|x-y|^{n-2 m}}\right) \psi+\Sigma_{i=1}^{2 m} C_{i} \int_{\mathbb{R}^{n}} u|x-y|^{-n+i} \eta^{(i)}\left(\frac{|x-y|}{R}\right) R^{-i} \\
= & \int_{\mathbb{R}^{n}} u^{(2 m)^{*}(t)-1} \frac{1}{|y|^{t}} \frac{\psi(x-y)}{|x-y|^{n-2 m}},
\end{aligned}
$$

where $C_{i}$ is some constant independent of $u(x)$. Since $u(x) \in L^{\frac{2 n}{n-2 m}}$, using Hölder's inequality for the second integration,

$$
\begin{aligned}
\int_{\mathbb{R}^{n}} u|x-y|^{-n+i} \eta^{(i)} R^{-i} & \leq C_{i} R^{-i}\left(\int_{\mathbb{R}^{n}}|u|^{\frac{2 n}{n-2 m}}\right)^{\frac{n-2 m}{2 n}}\left(\int_{\mathbb{B}_{2 R} \backslash \mathbb{B}_{R}}\left(|x-y|^{\frac{2 n(i-n)}{n+2 m}}\right)^{\frac{n+2 m}{2 n}}\right. \\
& \leq C_{i} R^{-i}\left(\int_{R}^{2 R} r^{\frac{2 n(i-n)}{n+2 m}} r^{n-1}\right)^{\frac{n+2 m}{2 n}} \rightarrow 0
\end{aligned}
$$

as $R \rightarrow \infty$. Therefore,

$$
u(x)=\int_{\mathbb{R}^{n}} u^{(2 m)^{*}(t)-1} \frac{1}{|y|^{t}} \frac{1}{|x-y|^{n-2 m}} d y .
$$
