Reading and writing files

A necessary step in every fMRI analysis with R is to be able to read/write data files.

Two formats are widely used by the neuroimaging community :

- ANALYZE 7.5
- NIFTI-1

Data import/export using the ANALYZE format
Data import/export using the NIFTI format
Conversion from ANALYZE to NIFTI
Issues in fMRI image orientations and display
Quaternions, rotations and the like
Various utilities
Spatial/temporal ICA using the GUI
Visualization of images using the GUI

The ANALYZE 7.5 format
Reading Analyze header files
Reading ANALYZE .img files
Writing ANALYZE .hdr files
Writing ANALYZE .img/.hdr pair files

The ANALYZE 7.5 format

The ANALYZE (7.5) format image consists of two files :

- `.img` : consists of one long stream of voxel intensities
- `.hdr` : header that contains information about the `.img` file

Note : SPM (96/99/2) uses the basic ANALYZE 7.5 format, but with three modifications / extensions : scale factor (`funused1`), voxel coordinates of image origin (`originator`) and a `.mat` file.
See : imaging.mrc-cbu.cam.ac.uk/imaging/FormatAnalyze

Data import/export using the ANALYZE format
Data import/export using the NIFTI format
Conversion from ANALYZE to NIFTI
Issues in fMRI image orientations and display
Quaternions, rotations and the like
Various utilities
Spatial/temporal ICA using the GUI
Visualization of images using the GUI

The ANALYZE 7.5 format
Reading Analyze header files
Reading ANALYZE .img files
Writing ANALYZE .hdr files
Writing ANALYZE .img/.hdr pair files

Summary of an ANALYZE header file

```
> f.analyze.file.summary(system.file("example.hdr",  
                                   package="AnalyzeFMRI"))
```

```
File name: /usr/lib/R/library/AnalyzeFMRI/example.img
```

```
Data Dimension: 4-D
```

```
  X dimension: 64
```

```
  Y dimension: 64
```

```
  Z dimension: 21
```

```
Time dimension: 1 time points
```

```
Voxel dimensions: 4 mm x 4 mm x 6 mm
```

```
Data type: signed short (16 bits per voxel)
```

The ANALYZE 7.5 format
Reading Analyze header files
Reading ANALYZE .img files
Writing ANALYZE .hdr files
Writing ANALYZE .img/.hdr pair files

Reading of an ANALYZE header file :

`f.read.analyze.header()`

Description:

Reads the ANALYZE image format .hdr header file into a list.

Usage:

```
f.read.analyze.header(file)
```

Arguments:

file: The .hdr file to be read

Value:

A list containing the information in the fields of the .hdr file.

Data import/export using the ANALYZE format
Data import/export using the NIFTI format
Conversion from ANALYZE to NIFTI
Issues in fMRI image orientations and display
Quaternions, rotations and the like
Various utilities

The ANALYZE 7.5 format
Reading Analyze header files
Reading ANALYZE .img files
Writing ANALYZE .hdr files
Writing ANALYZE .img/.hdr pair files

Reading ANALYZE header files

For a full description of the header file, please try :

```
res <- f.read.analyze.header(system.file("example.hdr",  
                                         package="AnalyzeFMRI"))
```

```
names(res)
```

```
res
```

```
?f.read.analyze.header
```

Reading parts of ANALYZE .img files

Without loading the whole file into **R** memory :

`f.read.analyze.slice()` Read one slice from a .img file

`f.read.analyze.slice.at.all.timepoints()`
Reads a slice at all time points
from a .img file

`f.read.analyze.tpt()` Read in a volume at one time point

`f.read.analyze.ts()` Read in one voxel time series

Data import/export using the ANALYZE format
Data import/export using the NIFTI format

The ANALYZE 7.5 format
Reading Analyze header files
Reading ANALYZE .img files
Writing ANALYZE .hdr files
Writing ANALYZE .img/.hdr pair files

Reading whole or part of ANALYZE .img files : examples

You can try :

```
file <- system.file("example.img",package="AnalyzeFMRI")
```

```
# Full img file:
```

```
f.read.analyze.volume(file)
```

```
# Parts of img file:
```

```
f.read.analyze.slice(file,slice=10,tpt=1)
```

```
f.read.analyze.slice.at.all.timepoints(file,slice=10)
```

```
f.read.analyze.tpt(file,tpt=1)
```

```
f.read.analyze.ts(file,x=30,y=30,z=10)
```

Reading Analyze header files
Reading ANALYZE .img files
Writing ANALYZE .hdr files
Writing ANALYZE .img/.hdr pair files

Writing ANALYZE .img/.hdr pair files

```
f.write_analyze(mat, file, size, pixdim, vox.units,  
               cal.units, originator)
```

writes an array to a .img/.hdr pair in
ANALYZE format

The NIFTI format

NIFTI-1 is adapted from the widely used ANALYZE 7.5 file format. NIFTI-1 uses the “empty space” in the ANALYZE 7.5 header to add several new features. These innovations include :

- Affine coordinate definitions relating voxel index (i,j,k) to spatial location (x,y,z) ;
- Codes to indicate spatio-temporal slice ordering for fMRI ;
- “Complete” set of 8-128 bit data types ;
- Standardized way to store vector-valued datasets over 1-4 dimensional domains ;
- Codes to indicate data “meaning” ;
- A standardized way to add “extension” data to the header ;
- Dual file (.hdr & .img) or single file (.nii) storage ;

and many more goodies.

Summary of a NIFTI header file

```
> f.nifti.file.summary(system.file("example-nifti.img",  
                                package="AnalyzeFMRI"))
```

```
File name: /usr/lib/R/library/AnalyzeFMRI/example-nifti.img  
Data Dimension: 3-D  
  X dimension: 53  
  Y dimension: 63  
  Z dimension: 46  
Time dimension: 1 time points  
Voxel dimensions: 3 x 3 x 3  
Data type: (8 bits per voxel)
```

Reading NIFTI header files : `f.read.nifti.header()`

Description:

Reads the NIFTI image format .hdr header file into a list

Usage:

```
f.read.nifti.header(file)
```

Arguments:

file: The .hdr file to be read

Value:

A list containing the information in the fields of the .hdr file.

Reading NIFTI header files

For a full description of the header file, please try :

```
res<-f.read.nifti.header(system.file("example-nifti.img",  
                                     package="AnalyzeFMRI"))
```

```
names(res)
```

```
res
```

```
?f.read.nifti.header
```

Reading ANALYZE or NIFTI header files : `f.read.header()`

The function `f.read.header()` can read **both** ANALYZE `.hdr` or NIFTI `.hdr` (or `.nii`) header files.

Description:

Reads the ANALYZE or NIFTI image format `.hdr` (or `.nii`) header file into a list. The format type is determined by first reading the magic field.

Usage:

```
f.read.header(file)
```

Arguments:

`file`: The `.hdr` (or `.nii`) file to be read

Reading parts of NIFTI .img (.nii) files

`f.read.nifti.slice()` Read one slice from a .img (or .nii) in NIFTI format

`f.read.nifti.slice.at.all.timepoints()`
Read a slice at all time points from a NIFTI .img (or .nii) file

`f.read.nifti.tpt()` Read in a volume at one time point

`f.read.nifti.ts()` Read in one voxel time series

Reading whole or part of NIFTI .img (.nii) files

You can try :

```
file <- system.file("example-nifti.img",  
                    package="AnalyzeFMRI")
```

```
# Whole .img (or .nii) file:  
f.read.nifti.volume(file)
```

```
# Parts of .img (.nii) file:  
f.read.nifti.slice(file,slice=10,tpt=1)  
f.read.nifti.slice.at.all.timepoints(file,slice=10)  
f.read.nifti.tpt(file,tpt=1)  
f.read.nifti.ts(file,x=30,y=30,z=10)
```

Reading whole ANALYZE or NIFTI .img (.nii) files

```
f.read.volume()
```

Description:

Reads the ANALYZE or NIFTI format image file into an array. Autodetects format type.

Usage:

```
f.read.volume(file)
```

Arguments:

file: The location of the image file to be read

Writing NIFTI .hdr files

```
f.basic.hdr.nifti.list.create(dim.mat, file.hdr)  
creates basic .hdr list in NIFTI format
```

```
f.write.list.to.hdr.nifti(L,file)  
writes a .hdr file in NIFTI format
```

```
f.complete.hdr.nifti.list.create(many parameters)  
Creates a complete list that can be used to  
write a .hdr file or the header part of  
a .nii file
```

Writing NIFTI .img/.hdr or .nii files

```
f.write_nifti(mat,file,size,L,nii)
```

Creates a .img/.hdr pair of files or a .nii file from a given array

mat: An array

file: Name of the file to be written, without .img or .hdr suffix

size: "float" (for 4 byte floats), "int" (2 byte integers) or "char" (1 byte integers).

L: header. If NULL, the list is created by the function else it should be provided.

nii: should we write only one .nii file or a .hdr/.img pair of files

The magicfield

`magicfield()` Get magicfield from the header
 of an image file

We read the magic field of a file to determine in which type it is (ANALYZE or NIFTI). The magic field can be either one of :

- "" for an ANALYZE .hdr/.img pair ;
- "ni1" for a NIFTI-1 .hdr/.img pair ;
- "n+1" for a NIFTI-1 .nii file.

Note : output can also be "nix" or "n+x", $x=0,\dots,9$, for (future) NIFTI-x files.

 - Various utilities
- Spatial/temporal ICA using the GUI
- Visualization of images using the GUI

Conversion from ANALYZE to NIFTI

`analyze2nifti()` Create a NIFTI file from an ANALYZE file

File storage

The image file consists of “raw” voxel intensity values that are stored sequentially. The image file’s voxel order is defined as follows :

- The file x-dimension (i) is defined as the dimension that changes most rapidly (i.e., each sequential voxel will fall in a different column and will therefore have a different x coordinate).
- The file y-dimension (j) changes more slowly than the x-dimension and more quickly than the z-dimension.
- The file z-dimension (k) is defined as the dimension that changes most slowly (e.g., all of the voxels for a given z-plane are stored before any of the voxels of the next z-plane).

- Data import/export using the ANALYZE format
- Data import/export using the NIFTI format

- Issues in fMRI image orientations and display
 - Quaternions, rotations and the like
 - Various utilities
- Spatial/temporal ICA using the GUI
- Visualization of images using the GUI

Some basic conventions

Be careful !

From voxel indices to spatial coordinates and back

Be careful !

Real-world coordinates do not necessarily correspond to voxel coordinates, i.e. how the image is stored in the file !

For instance, while real-world x coordinates might be **increasing** as you move from the left side of the brain to the right side, the actual associated voxel index i in the volume could be **decreasing**. In this case, the image is said to be stored in Right-to-Left format.

This is an example of a **left-handed** coordinate system and is the convention for ANALYZE format files.

- Data import/export using the ANALYZE format
- Data import/export using the NIFTI format
- Conversion from ANALYZE to NIFTI
- Issues in fMRI image orientations and display
 - Quaternions, rotations and the like
 - Various utilities
- Spatial/temporal ICA using the GUI
- Visualization of images using the GUI

Some basic conventions

Be careful !

From voxel indices to spatial coordinates and back

Be careful !

The opposite movement of voxel coordinates and real-world coordinates in the x dimension is what leads people to talk about ANALYZE files as being **stored in “radiological” format**.

However, images can be **displayed** radiologically or neurologically irrespectively of the format that the data are stored in. In fact, neurological and radiological conventions only relate to visualization of axial images.

In the ANALYZE and NIFTI formats, voxel data are retrieved in an \mathbf{R} array such that the location (in the file) of voxel (i, j, k) is :

$$i + (j - 1) \times \text{dim}[2] + (k - 1) \times \text{dim}[2] \times \text{dim}[3],$$

where $1 \leq i \leq \text{dim}[2]$, $1 \leq j \leq \text{dim}[3]$, $1 \leq k \leq \text{dim}[4]$.

The ANALYZE convention is a **left-handed** coordinate system (radiological convention) :

$$i \leftrightarrow x \text{ (R to L)}, \quad j \leftrightarrow y \text{ (P to A)}, \quad k \leftrightarrow z \text{ (I to S)}.$$

The default NIFTI convention is a **right-handed** system (neurological convention) :

$$i \leftrightarrow x \text{ (L to R)}, \quad j \leftrightarrow y \text{ (P to A)}, \quad k \leftrightarrow z \text{ (I to S)}.$$

Some basic conventions

Note that directions are given relative to the patient. For example :

- The left side of the brain is denoted by negative x coordinates, and regions in the right side of the brain are given by positive x coordinates. Thus, real-world x coordinates increase from **L**eft to **R**ight.
- Real-world y coordinates increase from **P**osterior to **A**nterior.
- Real-world z coordinates increase from **I**nferior to **S**uperior.

This is the way that the Talairach and Tournoux atlas is organized. This is an example of a **right-handed** real-world coordinate system : thumb = **R**, 2nd finger = **A**, middle finger = **S**.

Neurologist RAS axes

Three possible transformations

Note : The NIFTI format contains header information that allows the x, y, z directions of the brain to be assigned to other x, y, z arbitrary patient directions. This means that we assign directly (i, j, k) to special transformed (x, y, z) real-world coordinates. This is done via :

- **Method 1 :** Scaling ;
- **Method 2 :** Rigid body transform (scaling+rotation+shift) ;
- **Method 3 :** Affine transformation (scaling+shearing+rotation+shift), i.e. lines that are parallel before transformation remain parallel after transformation.

Method 1 : `qform.code = 0` and `sform.code = 0`

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} pixdim[2] \times i \\ pixdim[3] \times j \\ pixdim[4] \times k \end{pmatrix}$$

where

$$\begin{cases} pixdim[2] : & \text{voxel width in mm.} \\ pixdim[3] : & \text{voxel height in mm.} \\ pixdim[4] : & \text{slice thickness (interslice distance) in mm.} \end{cases}$$

Note : This is what is done for standard ANALYZE files, i.e. no orientation is given or assumed.

Issues in fMRI image orientations and display
Quaternions, rotations and the like
Various utilities
Spatial/temporal ICA using the GUI
Visualization of images using the GUI

Some basic conventions
Be careful!
From voxel indices to spatial coordinates and back

Method 2 : `qform.code > 0`

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \underbrace{\begin{bmatrix} r_{11} & r_{12} & r_{13} \\ r_{21} & r_{22} & r_{23} \\ r_{31} & r_{32} & r_{33} \end{bmatrix}}_{R:\text{rotation matrix}} \underbrace{\begin{pmatrix} \text{pixdim}[2] \times i \\ \text{pixdim}[3] \times j \\ qfac \times \text{pixdim}[4] \times k \end{pmatrix}}_{\text{Scaling}} + \underbrace{\begin{pmatrix} qoffset.x \\ qoffset.y \\ qoffset.z \end{pmatrix}}_{\text{Translation}}$$

We have $qfac = \text{pixdim}[1] = \pm 1$. The R (proper) rotation matrix is encoded into NIFTI files using quaternions parameters (quatern.b, quatern.c and quatern.d), see later.

Issues in fMRI image orientations and display
Quaternions, rotations and the like
Various utilities
Spatial/temporal ICA using the GUI
Visualization of images using the GUI

Some basic conventions
Be careful!
From voxel indices to spatial coordinates and back

Method 3 : `sform.code > 0`

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \underbrace{\begin{bmatrix} srow.x[1] & srow.x[2] & srow.x[3] & srow.x[4] \\ srow.y[1] & srow.y[2] & srow.y[3] & srow.y[4] \\ srow.z[1] & srow.z[2] & srow.z[3] & srow.z[4] \end{bmatrix}}_{\text{affine matrix}} \begin{pmatrix} i \\ j \\ k \\ 1 \end{pmatrix}$$

Note : SPM (old versions) uses external `.mat` files (in addition to the Analyze `.img/.hdr`) to store affine transformations.

The function `ijk2xyz()`

```
ijk2xyz(ijk=c(1,1,1),method=2,L)
```

Arguments:

`ijk`: matrix. Each column of `ijk` should contain a voxel index coordinates (i,j,k) to be mapped to its (x,y,z) real coordinates in some other space

`method`: 1 (`qform.code=sform.code=0`), 2 (`qform.code>0`, rigid transformation) or 3 (`sform.code>0`, affine transformation).

`L`: header list of a NIFTI file

The function `xyz2ijk()`

```
xyz2ijk(xyz=c(1,1,1),method=2,L)
```

Arguments:

`xyz`: matrix. Each column of `xyz` should contain a voxel real world index coordinates (x,y,z) to be mapped to its (i,j,k) voxel index coordinates in the dataset

`method`: 1 (qform.code=sform.code=0), 2 (qform.code>0, rigid transformation) or 3 (sform.code>0, affine transformation).

`L`: header list of a NIFTI file

The quaternion representation (a, b, c, d) is chosen for its compactness in representing rotations. We have $a^2 = 1 - b^2 - c^2 - d^2$ and

$$R = \begin{bmatrix} a^2 + b^2 - c^2 - d^2 & 2bc - 2ad & 2bd + 2ac \\ 2bc + 2ad & a^2 + c^2 - b^2 - d^2 & 2cd - 2ab \\ 2bd - 2ac & 2cd + 2ab & a^2 + d^2 - c^2 - b^2 \end{bmatrix}$$

Note that rotations stored in NIFTI headers (using quaternions) are always proper ($\det(R) = 1$). Improper rotation is the combination of an ordinary rotation of 3D Euclidean space, that keeps the origin fixed, with an inversion (x goes to $-x$ for example). An improper rotation of an object thus produces a rotation of its mirror image. Note also that the `qfac=pixdim[1]` parameter is necessary to handle the case of improper rotations.

Various geometrical utilities

<code>mat34.to.TRSZ()</code>	Affine 4x4 (or 3x4) matrix to Translation, Rotation, Shear and Scale
<code>mat34.to.TZSR()</code>	Affine 4x4 (or 3x4) matrix to Translation, Scale, Shear and Rotation
<code>nifti.quatern.to.mat44()</code>	Quaternion (etc..) to affine 4x4 matrix
<code>Q2R()</code>	Quaternion to (proper) rotation
<code>R2Q()</code>	(proper) Rotation to quaternion

Various utilities

- `diminfo2fps()` Extract `freq.dim`, `phase.dim` and `slice.dim` fields from the one byte `dim.info` field of a NIFTI header file.
- `fps2diminfo()` Encode `freq.dim`, `phase.dim` and `slice.dim` fields into the one byte `dim.info` field of a NIFTI header file
- `st2xyzt()` Encode space and time dimensions fields into the one byte `xyzt.units` field of a NIFTI header file.
- `xyzt2st()` Extract space and time dimensions fields from the one byte `xyzt.units` field of a NIFTI header file.

Various utilities

`fourDto2D()` Transforms a 4D image into a 2D image matrix of size $t_m \times v_m$

`threeDto4D()` To read t_m functional images files in ANALYZE or NIFTI format, and concatenate them to obtain one 4D image file in Analyze (hdr/img pair) or Nifti format (hdr/img pair or single nii) which is written on disk.

`twoDto4D()` This function transforms a 2D matrix of size $t_m \times v_m$ containing images in each row into a 4D array image.

The problem of blind source separation

- Each voxel contains a **mixing** of several **source signals** :
heart rate, eyes movement, respiratory cycle, stimulus of the experiment, ...
- These signals are mixed in different proportions depending on the voxel. The weighting changes with time.
- Thus, we are facing here a **source separation problem**.
