

The Asymmetric Baeyer-Villiger Oxidation

Traditional Synthetic Methods Versus Enzymes

Craig Seymour (cseymou2 at
illinois.edu)

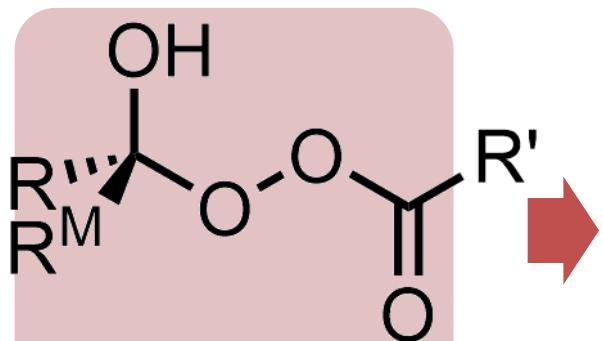

Group Meeting Presentation

16 July 2013

Online Version

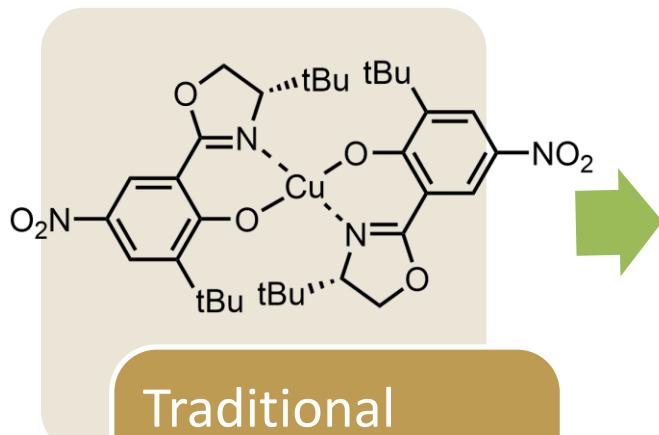

Outline

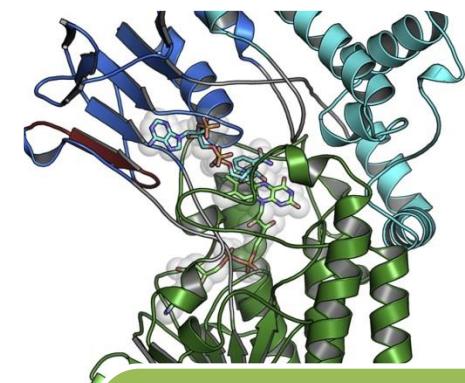

Background

- History
- Mechanism
- Chem, Regio, Stereoselectivity

Traditional Chemical Methods

- Metal Catalyzed
- Chiral Acid

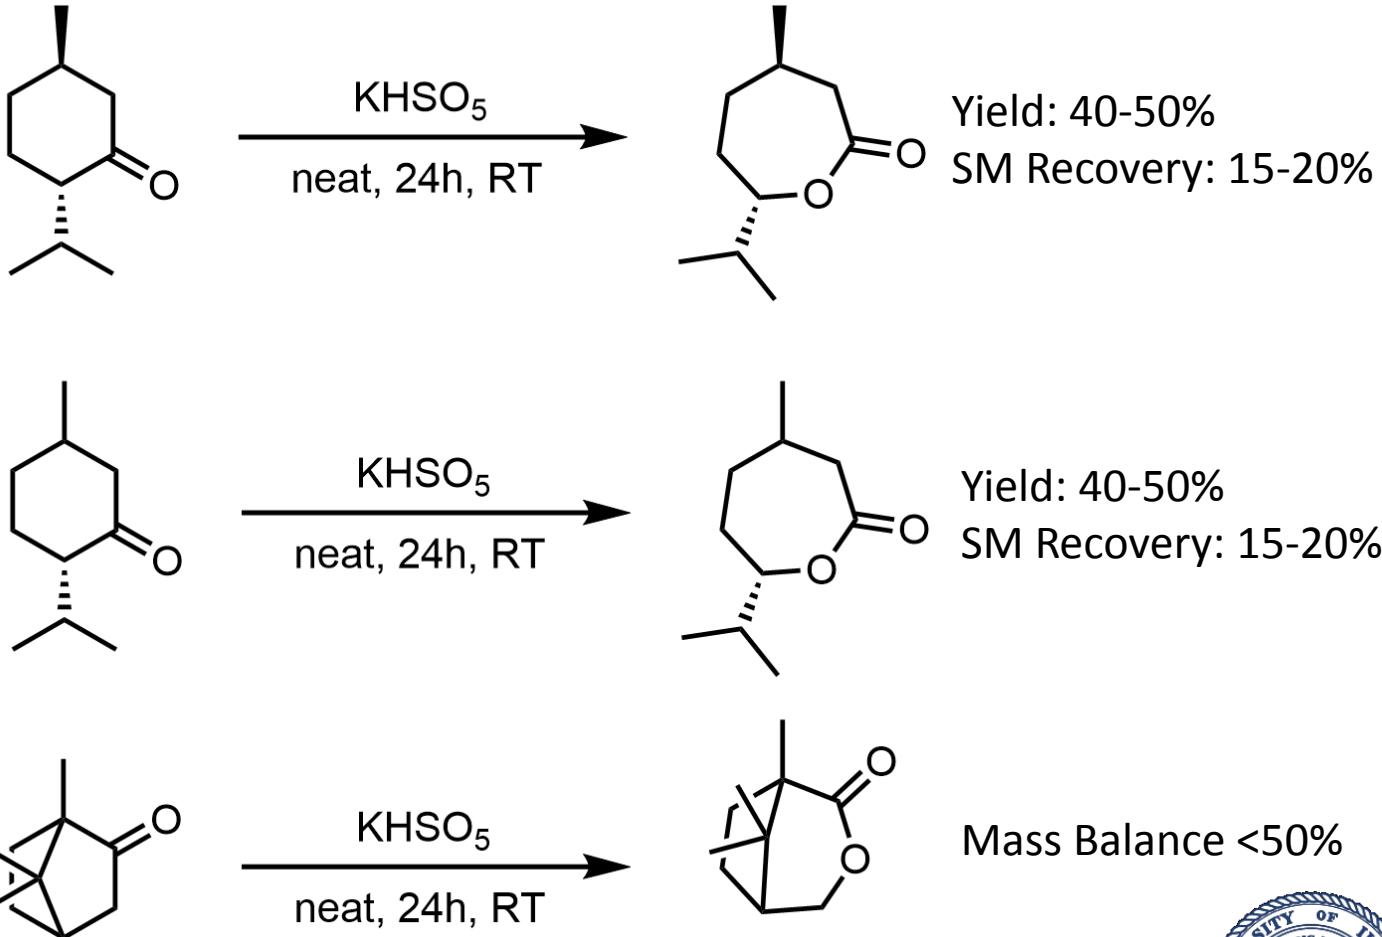

Enzyme Methods

- Background
- Structural Mechanism
- How to use

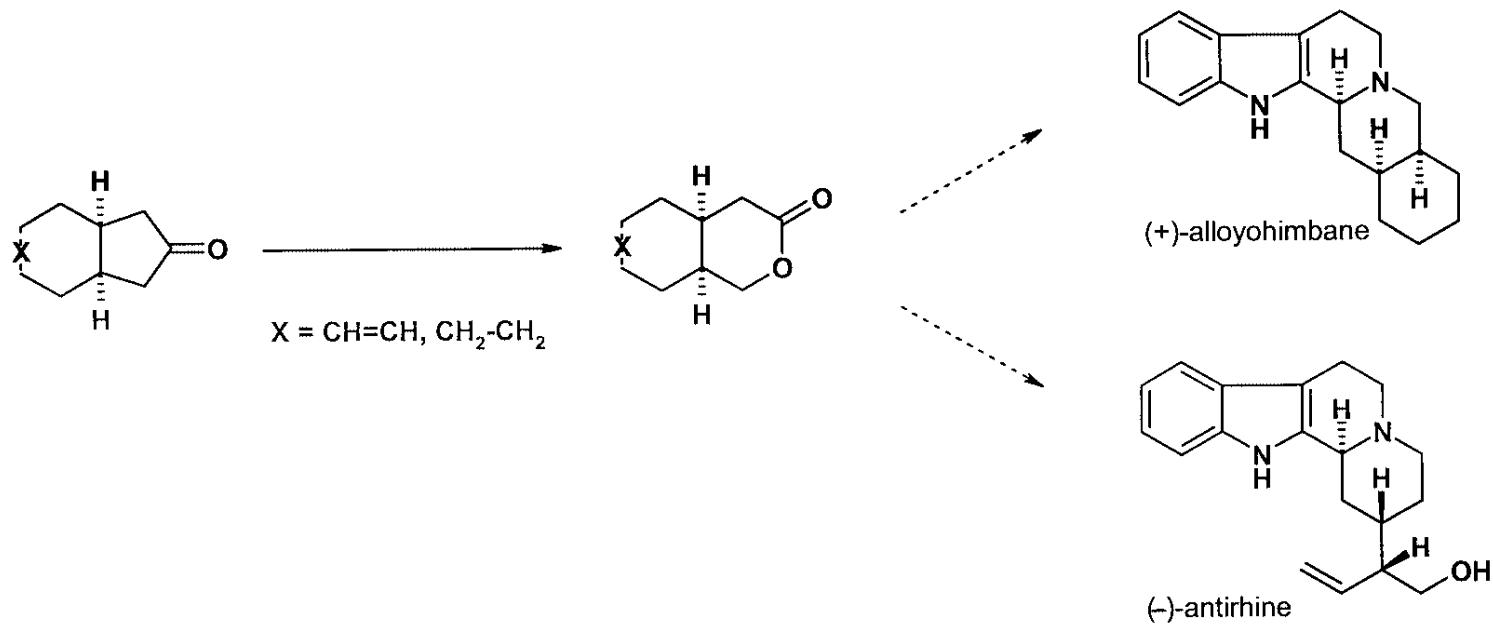

The Baeyer-Villiger Reaction

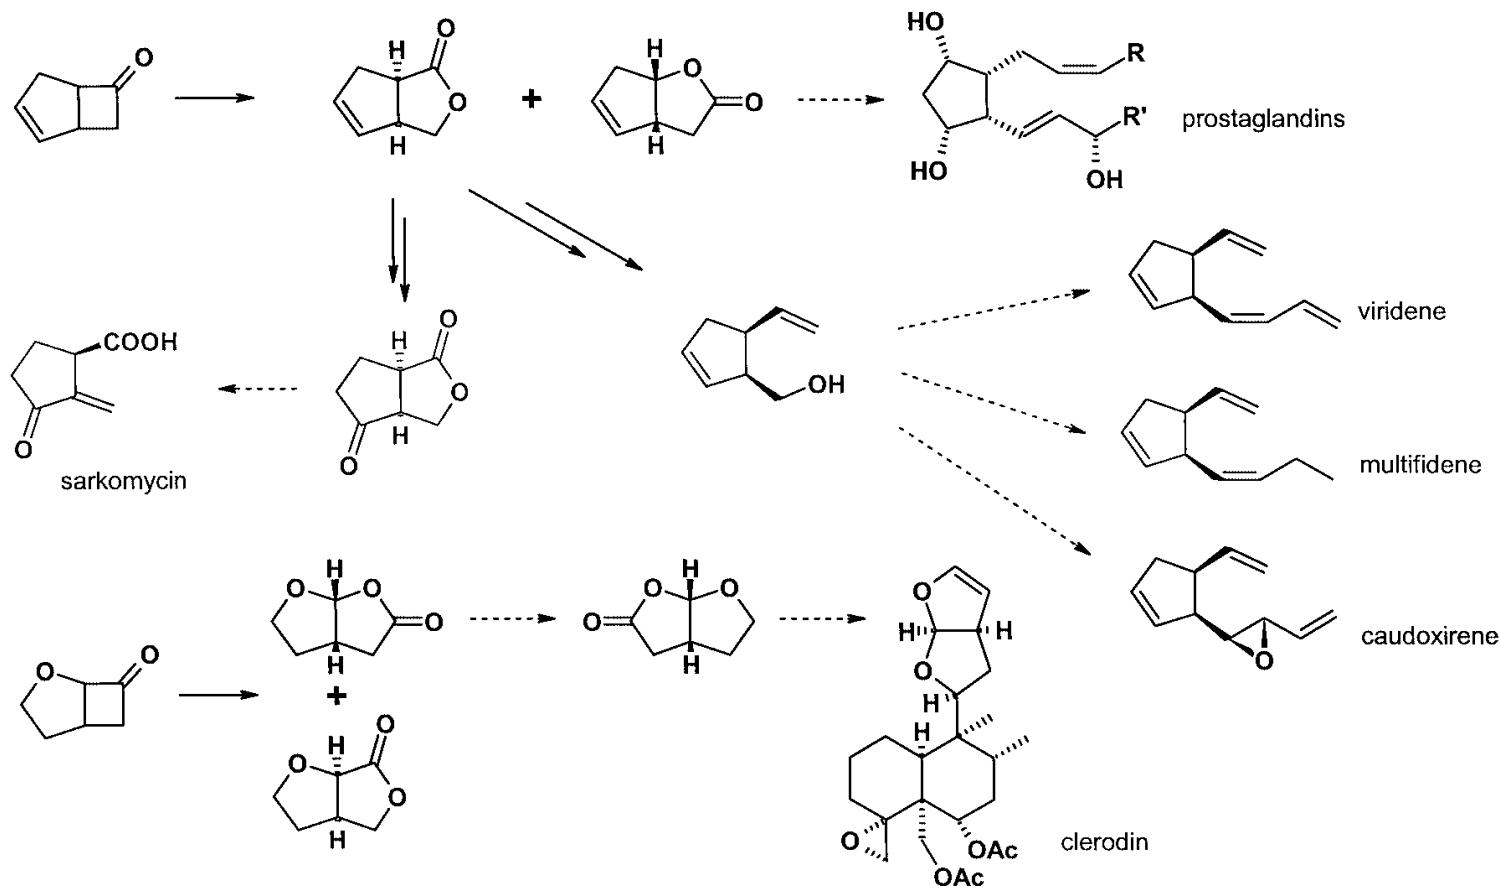

Baeyer and Villiger, 1899

The Baeyer-Villiger Reaction: Applications

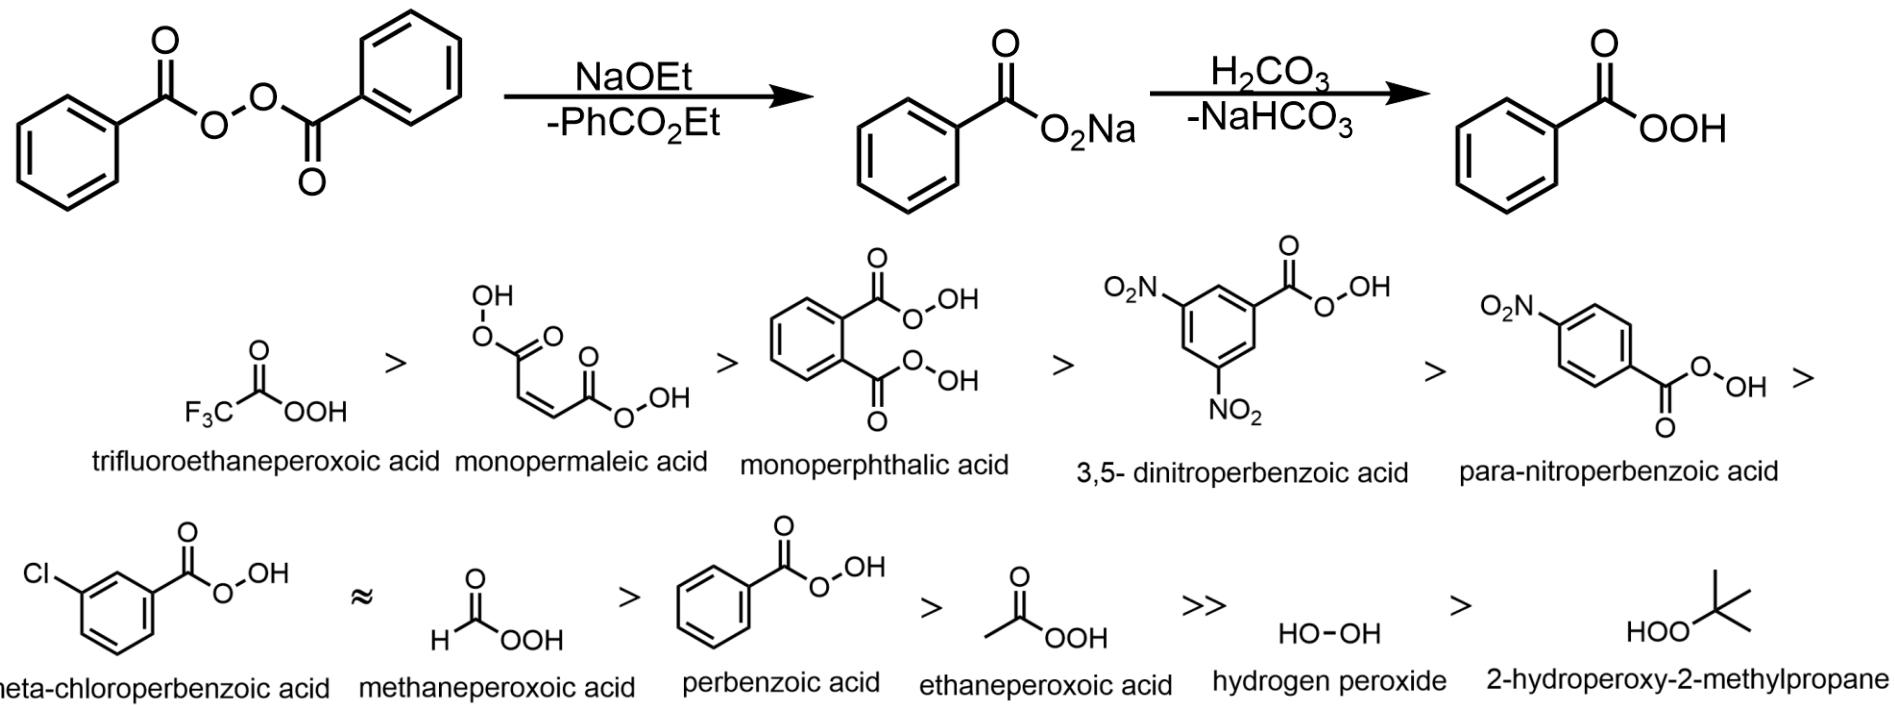

The Baeyer-Villiger Reaction: Applications

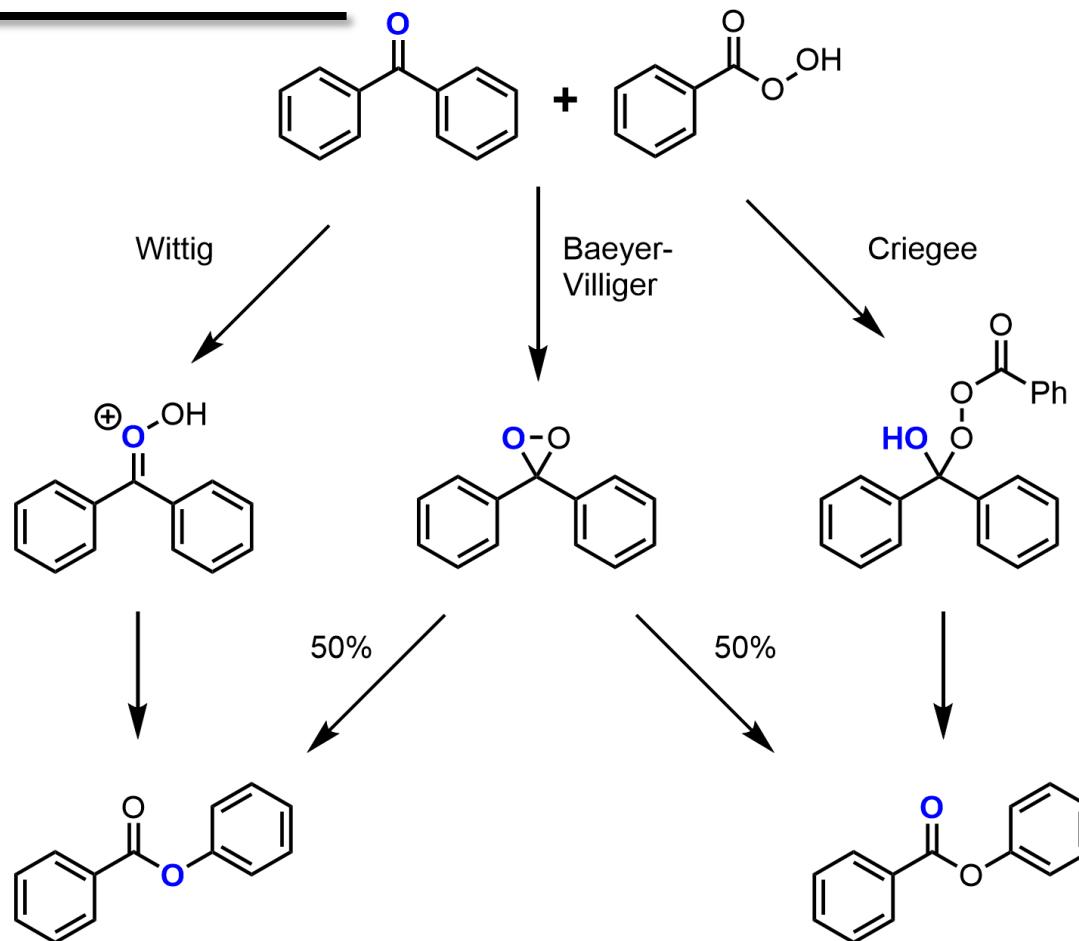

The Baeyer-Villiger Reaction

Baeyer and Villiger, 1900

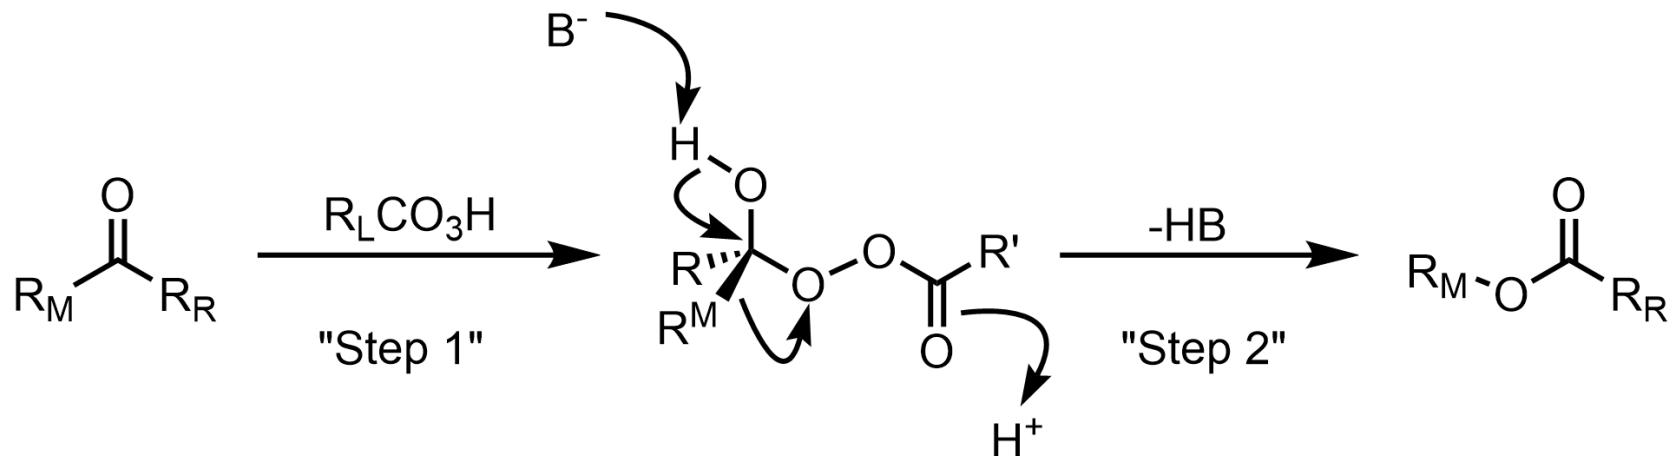

The BV Reaction: Mechanism

Doering and Dorfman, 1953

The BV Reaction: Mechanism

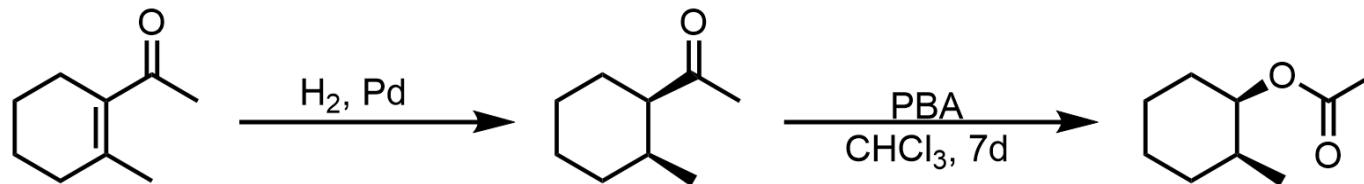

- Step one can be catalyzed by acid or base. Base is typically not used as it can lead to racemization.
- Step two is typically the rate determining step. Step one can become the rate determining step if the ketone is significantly electron deficient or if there is steric bulk around the carbonyl.

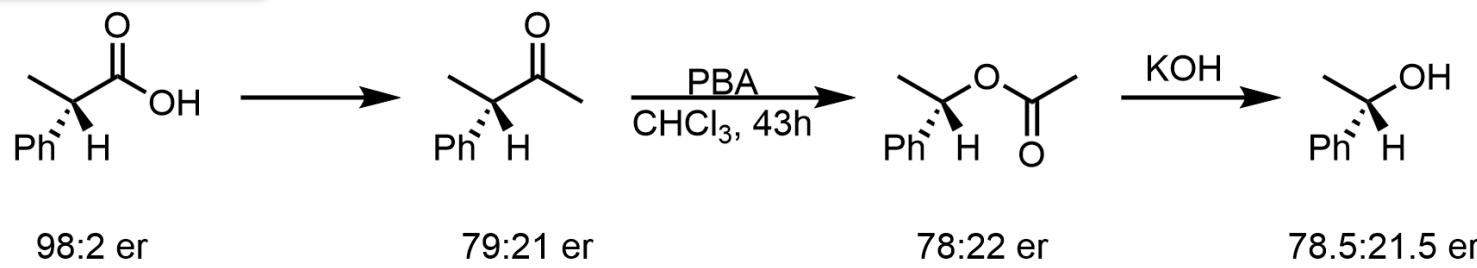

The BV Reaction: Retention Of Stereochemistry

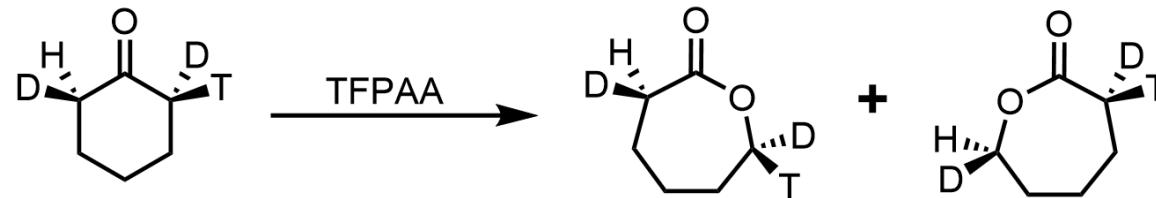

Turner, 1950

Mislow and Brenner, 1953

Benner, 1983

The BV Reaction: Migratory Aptitude

- General scale:

tertiary alkyl > cyclohexyl > secondary alkyl > benzyl > phenyl > primary alkyl > cyclopentyl ~ cyclopropyl > methyl

- Groups that are better able to stabilize positive charge are more apt to migrate.

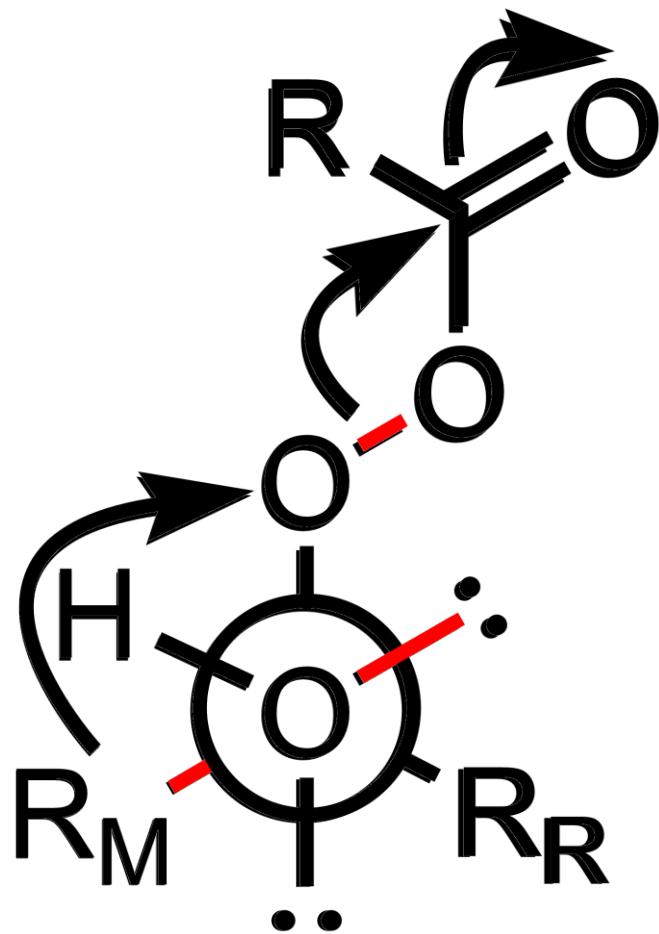

- α -ethers and α -acetate groups directs migration.

- Restriction of a substrate's conformation can prevent the proper antiperiplanar orientation for required migration.

- The Organic Reactions chapter on the Baeyer-Villiger Oxidation provides 1000's of examples. (Volume 43 in our library)

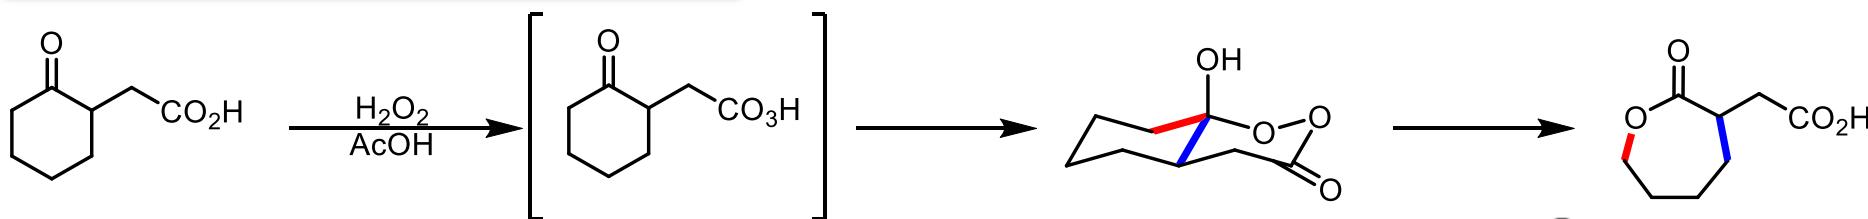

The BV Reaction: Stereoelectronic Requirements

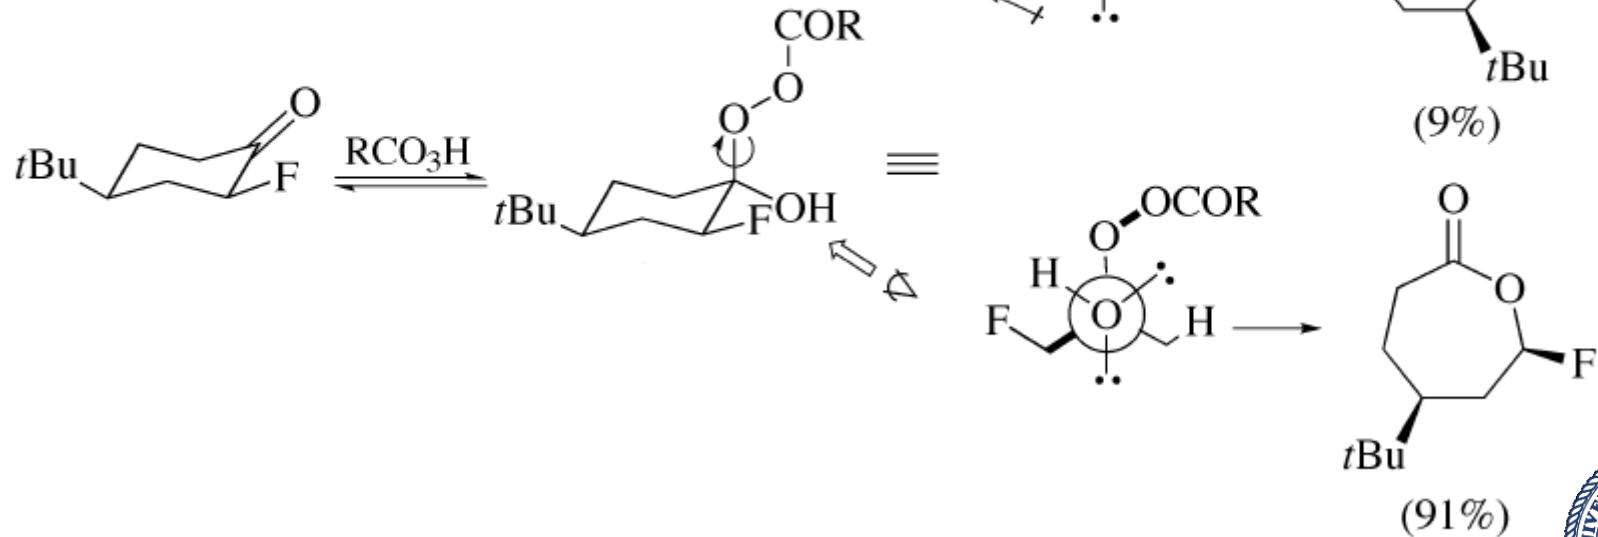

Primary Stereoelectronic Requirements

Chandrasekhar and Roy, 1994

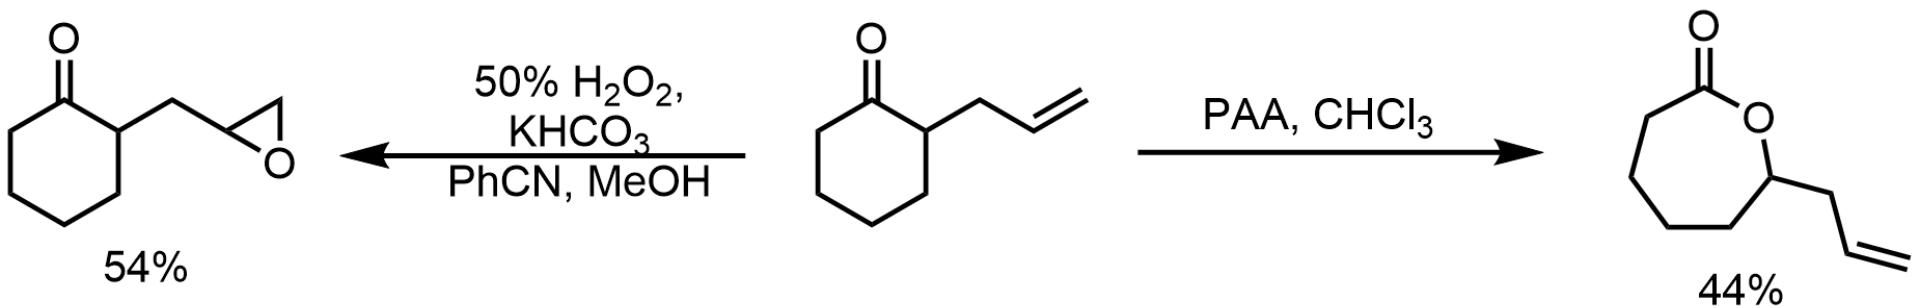

Crudden, 2000

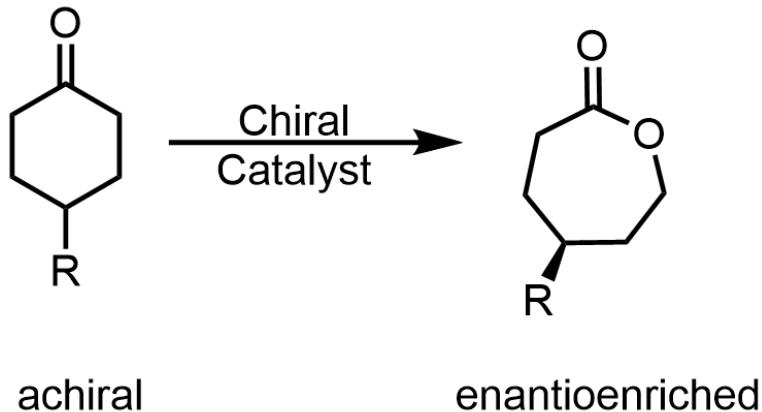

The BV Reaction: Chemoselectivity

- Baeyer-Villiger type oxidations can occur in the presence of amino acids, amines, pyridines, or anilines.
- Chemoselectivity in the presence of olefins depends upon structure and oxidizing agent.
 - Olefin oxidation of non-conjugated acyclic enones with peracids is generally faster than the Baeyer-Villiger Reaction
 - Electron poor olefins typically undergo BV Oxidation.

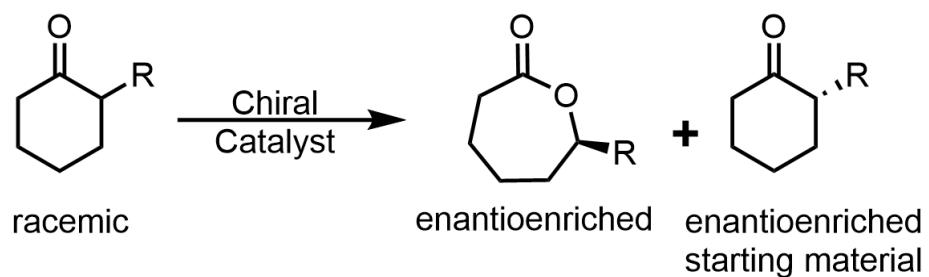

Asymmetric Synthesis v. Kinetic Resolution

Asymmetric Synthesis

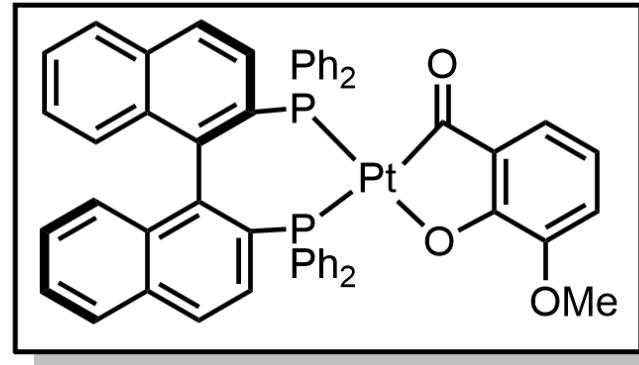

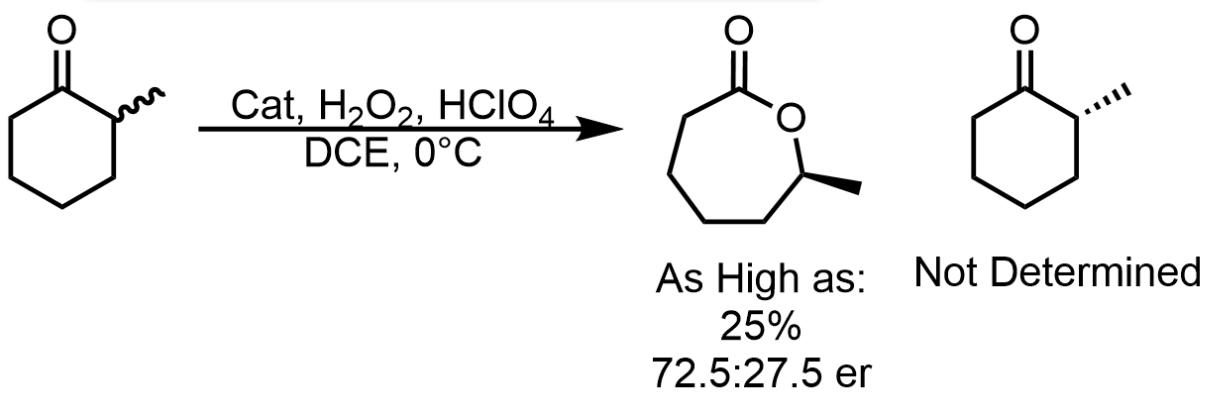

Kinetic Resolution

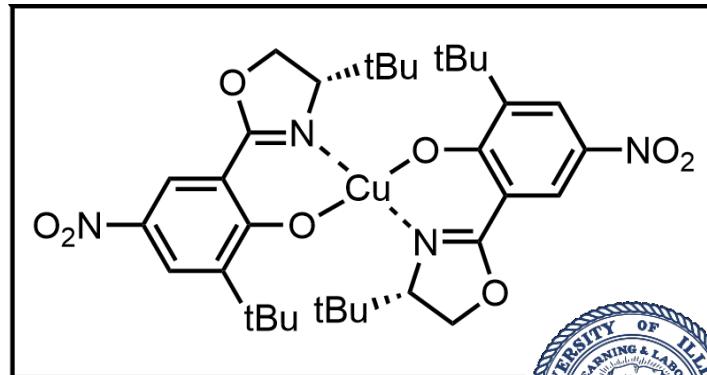

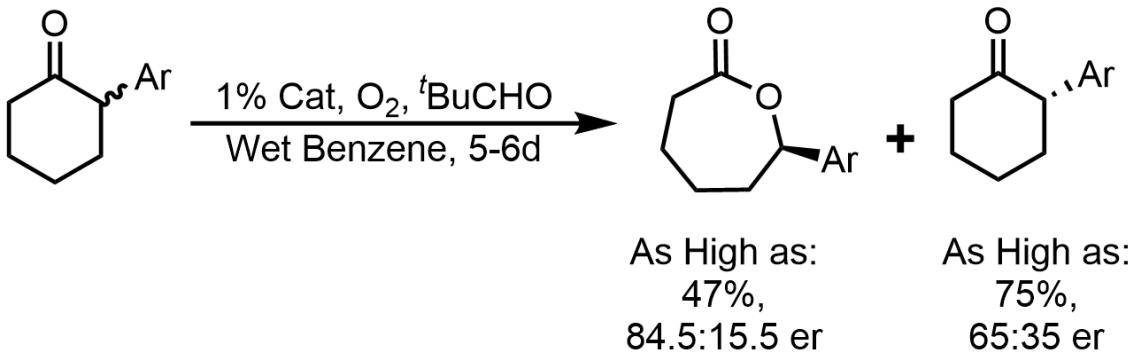

First Catalytic Enantioselective BV Reaction via Kinetic Resolution

Strukul, December 1993

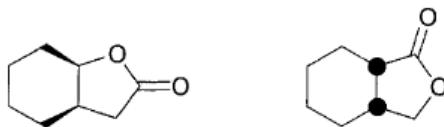

Bolm, April 1994

Cyclobutanones with Bolm's Methodology

Bolm, 1997

7	59	93	59 (1:1.3)

^a Ratio after work-up and product isolation.

First Catalytic Enantioselective BV Reaction Using Achiral Substrates

Bolm, 1997

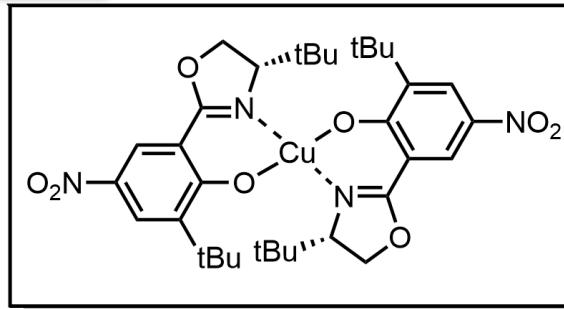

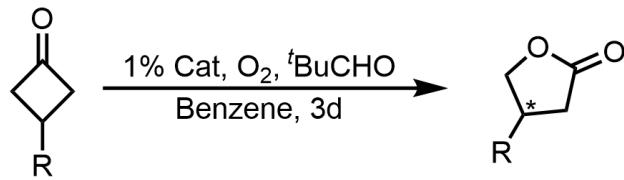

Table. Asymmetric Baeyer-Villiger-type oxidation of cyclobutanones with dioxygen and pivaldehyde catalyzed by 1 mol% of

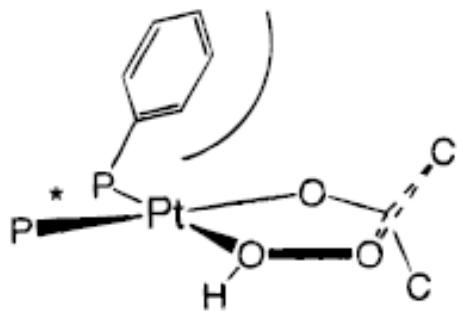

- 4-substituted cyclohexanones did not work using Bolm's methodology. 3-substituted where chosen as they are more reactive in Bayer-Villiger reactions.
- There was one example of 95.5:4.5 er with a bulky tricyclic ketone.

Group Problem

Enzyme Catalyzed BV Reaction

Whole Cell Vs. Isolated Protein

Whole Cell

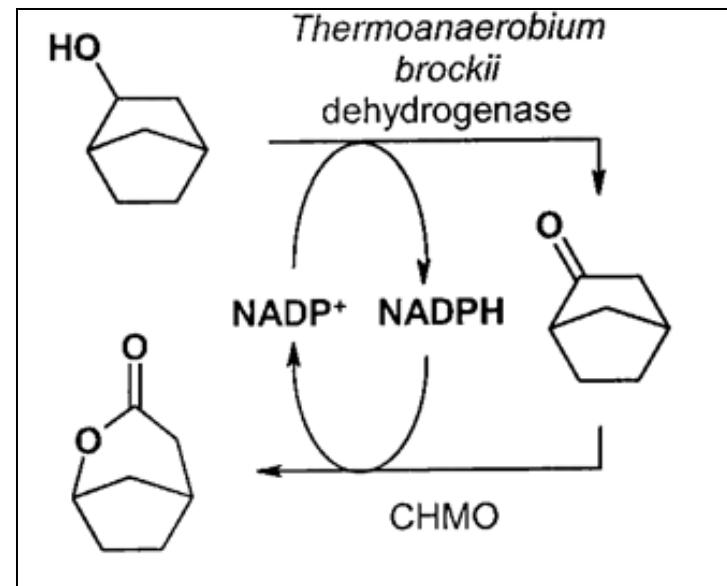

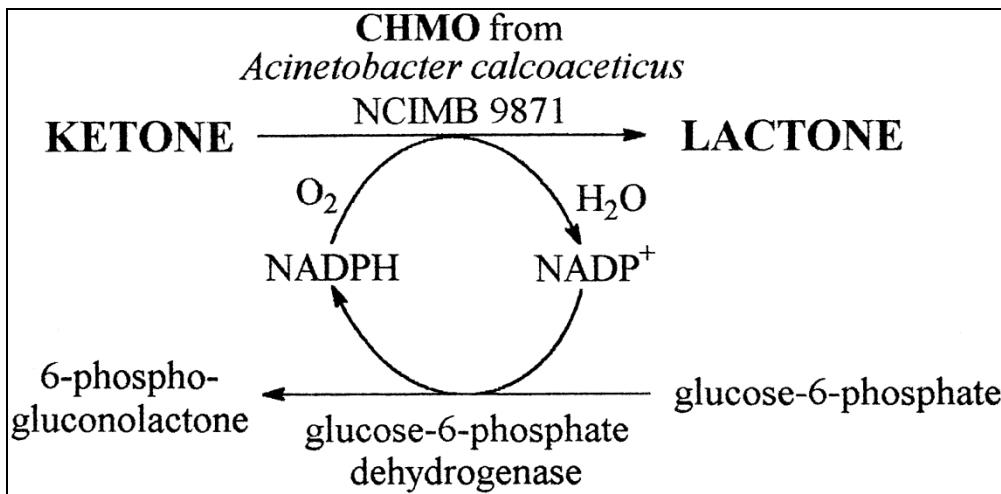

- Has a built in method to recycle NADP+.
- No Purification.
- Regrowable source.
- Other enzymes can perform undesired reactions.
 - Mitigated with over-expression
- More “resilient” to reaction conditions.

Isolated Protein

- Regeneration cycled must be established.
- Required Purification.
- Can only be used a few times (<4).
- Eliminates side reactions
- May lose activity based on reaction conditions.

97.2:2.5 er

Conclusions

- The enzymatic BV oxidation is superior to current chemical methods.
- The enzymatic BV is becoming more available to the organic chemist and is increasing in versatility.
- There is still room for development using traditional chemical synthesis.
