# The Outer Worlds...

- Beyond the orbit of Mars, the low temperatures of the solar nebula allowed condensing bodies there to capture hydrogen and hydrogen-rich gases
- This, together with the vast amount of material in the outer Solar System, lead to the creation of the four large Jovian planets – Jupiter, Saturn, Uranus, and Neptune
- Composed mainly of gaseous and liquid hydrogen and its compounds, these planets lack solid surfaces and *may* have cores of molten rock
- The dwarf planets Pluto and Eris are exceptions to these rules resembling the ice and rock makeup of the giant planets' larger moons
- The moons of the outer planets form families of miniature solar systems, although individually each moon presents a unique combination of size, structure, and appearance

# Jupiter

- Jupiter is the largest planet both in diameter and mass: more than  $10\times$  Earth's diameter and  $300\times$  the mass!
- Dense, richly colored parallel cloud bands cloak the planet
- Atmosphere is mainly H, He,  $\text{CH}_4$ ,  $\text{NH}_3$ , and  $\text{H}_2\text{O}$

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

Courtesy of NASA

# Cloudtops

- Clouds appear to be particles of water, ice, and ammonia compounds
- Bright colors of clouds may come from complex organic molecules or compounds of sulfur or phosphorous
- Jupiter rotates once about every 10 hours with this fast rotation leading to a significant equatorial bulge

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

Courtesy of NASA

# Jupiter's Interior Structure

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

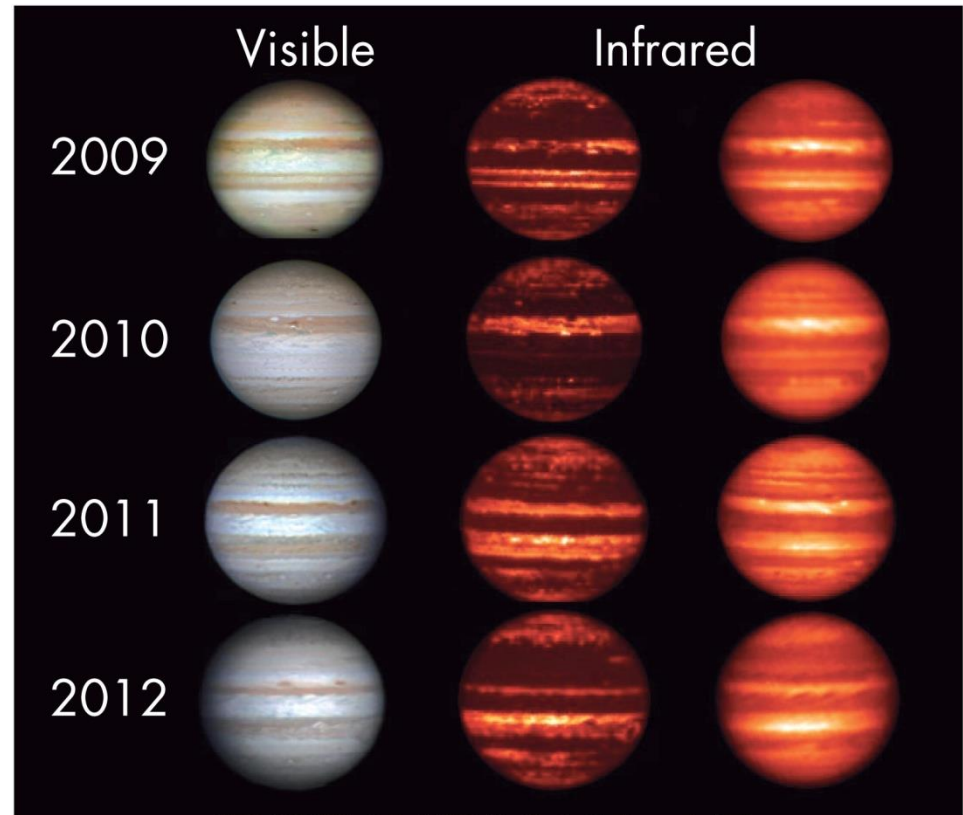

- Jupiter's average density is  $1.3 \text{ g/cm}^3$  – indicates an interior composed of very light elements
- Interior becomes increasingly dense with depth, gas turning to liquid hydrogen about 10,000 km down
- Deeper still, liquid hydrogen compresses into liquid metallic hydrogen, a material scientists only recently created in tiny high-pressure chambers
- An iron rocky core, a few times bigger than the Earth, probably resides at the center

# Jupiter's Interior

- Jupiter, with a core temperature of about 30,000 K, emits more energy than it receives
  - Possibly due to heat left over from its creation
  - Planet may still be shrinking in size converting gravitational energy into heat

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

NASA/IRTF/JPL-Caltech/NAOJ/A. Wesley/A. Kazemoto/C. Go

# Jupiter's Atmosphere

- General convection pattern:
  - Heat within Jupiter carries gas to the top of the atmosphere, forming white zones
  - High altitude gas radiates into space, cools and sinks, becoming transparent (belts)

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

- A** Hot material rises to top of atmosphere and spreads toward pole and equator.

# Jupiter's Jet Streams

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

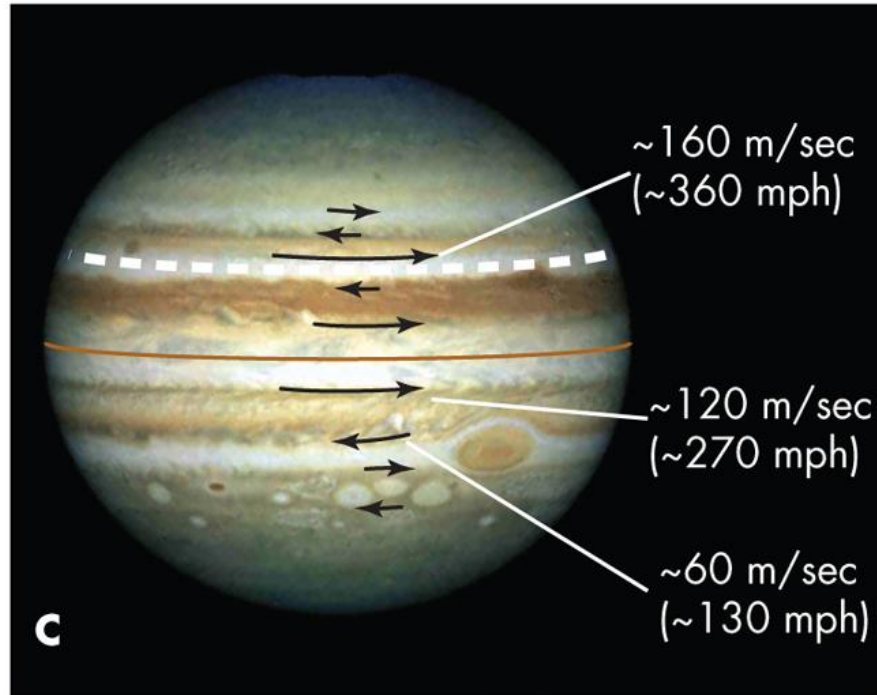

**B** Coriolis effect deflects gas moving away from zones toward pole toward the east, and deflects gas moving toward equator toward the west.

- Coriolis effect turns rising and sinking gases into powerful jet streams (about 300 km/hr) that are seen as cloud belts

# Jupiter's Winds

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

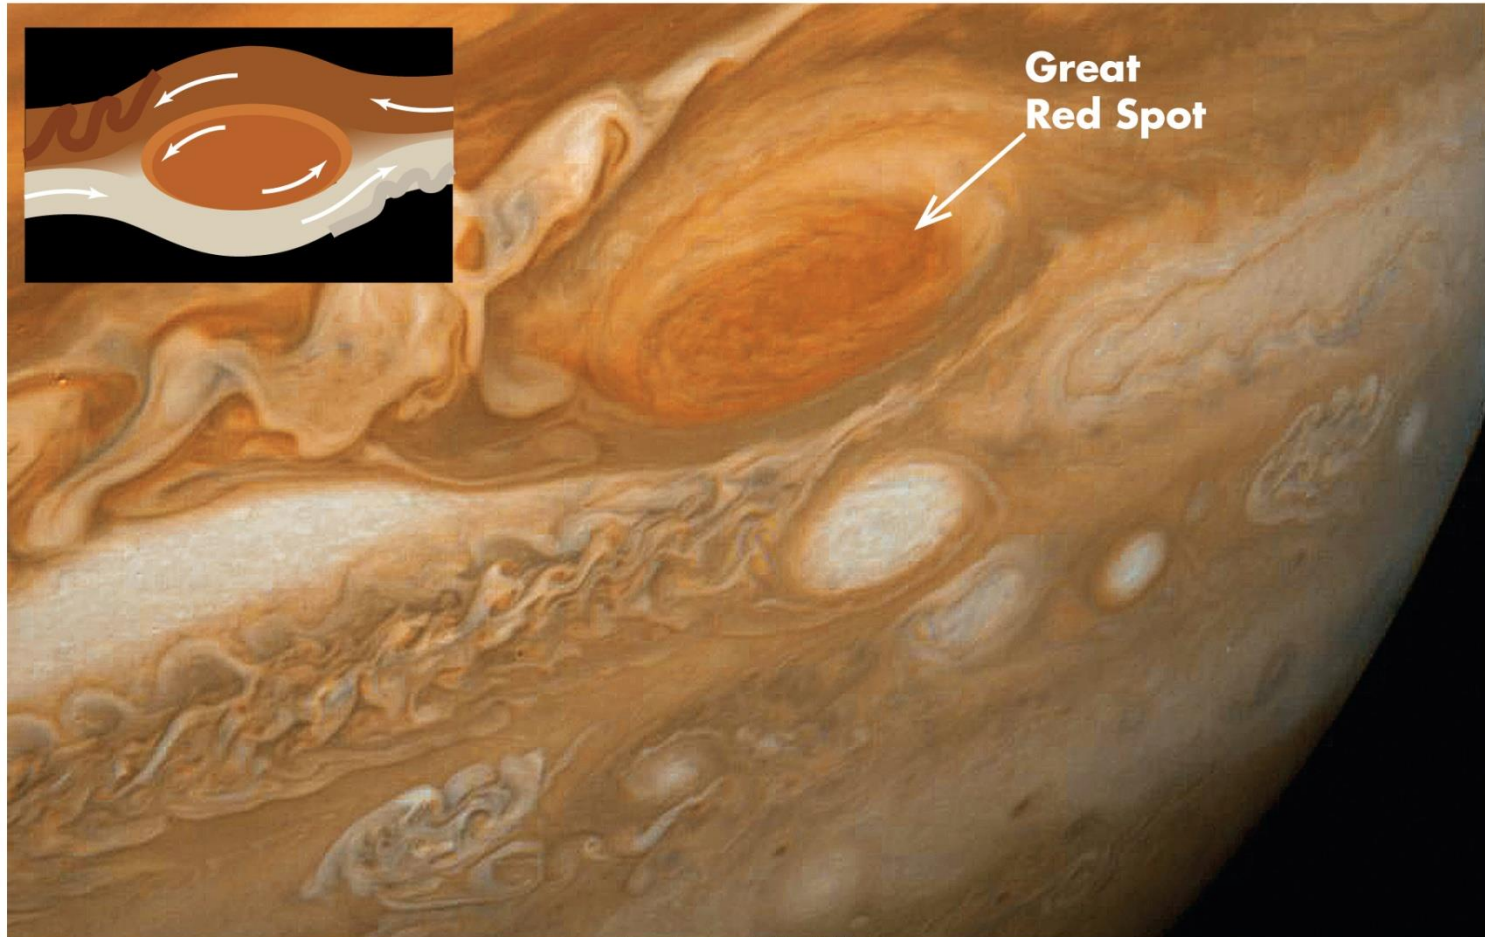

c: Courtesy of NASA

- Adjacent belts, with different relative speeds, create vortices of various colors, the largest being the Great Red Spot, which has persisted for over 300 years

# The Great Red Spot

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

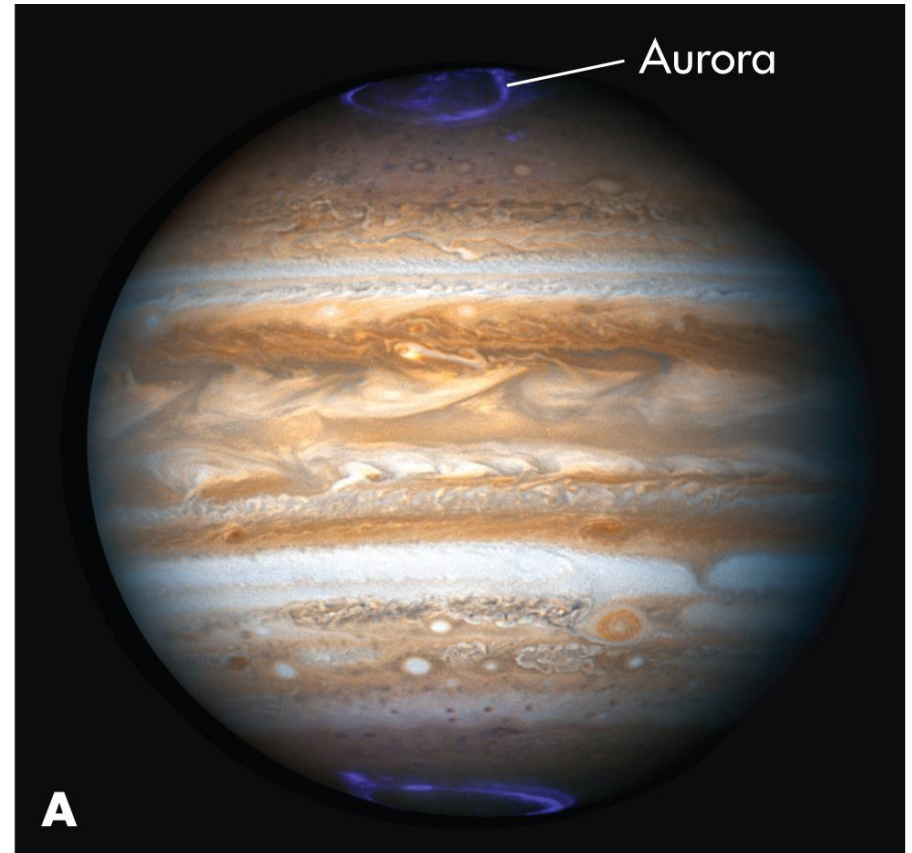

Courtesy of NASA/JPL

# Jupiter's Magnetic Field

- Convection in the deep metallic liquid hydrogen layer coupled with Jupiter's rapid rotation creates a powerful magnetic field
  - 20,000× stronger than the Earth's field, it is the largest planetary magnetic field
  - Jupiter's auroral activity and intense radio emissions are indicative of its magnetic field

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

a: NASA/ESA, The Hubble Heritage Team. Acknowledgment: H. Weaver (JHU/APL) and A. Simon-Miller (NASA/GSFC)

# Aurora and Lightning

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

b: Courtesy of NASA/JPL

- Magnetic field also traps charged particles far above the planet in regions resembling the Earth's Van Allen radiation belts
- Lightning in clouds has been observed

# Jupiter's Rings

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

a: NASA/JPL

Jupiter has a system of rings made of tiny particles of rock dust and held in orbit by Jupiter's gravity

- Solar radiation and collisions with charged particles trapped in Jupiter's magnetic field exert a friction on the ring dust that will eventually cause the dust to drift into the atmosphere
- To maintain the rings, new dust must be provided – possibly from collision fragments ejected from the Jovian moons

# The Moons of Jupiter

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

(Moon): © Digital Vision RF/Punchstock; (Amalthea): NASA/JPL/Cornell University;  
(Io, Ganymede, Callisto): NASA Jet Propulsion Laboratory (NASA-JPL); (Europa): NASA

- Jupiter currently has 63 natural satellites or moons
- Four innermost moons are called the Galilean Moons

# Planets in Miniature

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

(Moon): © Digital Vision RF/Punchstock; (Amaltheo): NASA/JPL/Cornell University;  
(Io, Ganymede, Callisto): NASA Jet Propulsion Laboratory (NASA-JPL); (Europa): NASA

- Except for Europa, all are larger than the Moon
- Formed in a process similar to the formation of the Solar System – the density of these satellites decreases with distance from Jupiter

# Io

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

a: NASA Jet Propulsion Laboratory (NASA-JPL)

- Gravitational tidal forces induced from Jupiter and Europa keeps Io's interior hot
- Volcanic plumes and lava flows are the result

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

NASA Jet Propulsion Laboratory (NASA-JPL)

# Europa

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

a: NASA

- Very few craters indicate interior heating by Jupiter and some radioactive decay
- Surface looks like a cracked egg indicating a “flow” similar to glaciers on Earth
- Heating may be enough to keep a layer of water melted below the crust

# Liquid Water Ocean on Europa?

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

a: NASA; b: NASA Jet Propulsion Laboratory (NASA-JPL)

# Ganymede and Callisto

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

(Ganymede, Callisto): NASA Jet Propulsion Laboratory (NASA-JPL)

- Look like our Moon with grayish brown color and covered with craters
- However, their surfaces are mostly ice – whitish craters a very good indication of this
- Callisto may have subsurface liquid water
- Ganymede is less cratered than Callisto indicating maria-type formations although tectonic movement cannot be ruled out

# Other Observations

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

(Io, Ganymede, Callisto): NASA Jet Propulsion Laboratory (NASA-JPL); (Europa): NASA

- Galilean average densities indicate their interiors to be composed mainly of rocky material
- Differentiation may have allowed iron to sink to core
- Rest of Jupiter's moons are much smaller than the Galilean satellites and they are cratered
- Outermost moons have orbits that have high inclinations suggesting that they are captured asteroids

# Saturn

- Saturn is the second largest planet,  $10\times$  Earth's diameter and  $95\times$  Earth's mass
- Its average density of  $0.7\text{ g/cm}^3$  is less than that of water
- Low density, like Jupiter, suggests a composition mostly of hydrogen and its compounds

(left); NASA/JPL/Space Science Institute; (right); NASA and The Hubble Heritage Team (STScI/AURA) Acknowledgement: R.G. French (Wellesley College), J. Cuzzi (NASA/Ames), L. Dones (SwRI), and J. Lissauer (NASA/Ames)

Saturn looks different from Jupiter – temperature is low enough for ammonia gas to freeze into cloud particles that veil its atmosphere's deeper layers

# Interior of Saturn

- Saturn radiates more energy than it receives, but unlike Jupiter, this energy probably comes from the

conversion of gravitational energy from falling helium droplets as they condense and fall in Saturn's interior

# Storms on Saturn

- Major storms can push up to where they are visible near the surface layers.
- Saturn's north pole is surrounded by an unusual hexagonal jet stream.
  - Within it, clouds and storms can be seen, with a deep hurricane-like vortex over the pole where gas spirals downward.

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

# The Rings of Saturn

- Rings are wide but thin
  - Main band extends from about 30,000 km above its atmosphere to about twice Saturn's radius (136,000 km)
  - Faint rings can be seen closer to Saturn as well as farther away
  - Thickness of rings: a few hundred meters
  - Visible A, B and C rings, from outside in

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

NASA/JPL/Space Science Institute

# Ring Structure

- Rings not solid, but made of a swarm of individual bodies
  - Sizes range from centimeters to meters
  - Composition mainly water, ice, and carbon compounds and is not uniform across rings

# Ring Gaps

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

NASA/JPL/Space Science Institute

- Large gaps due to resonances with Saturn's moons located beyond the rings
- Narrow gaps due to complex interaction between ring particles and tiny moons in the rings
- *Shepherding satellites* may deflect ring particles into a narrow stream between them.

# Destructive Tidal Forces

- Any object held together solely by gravity will break apart by tidal forces if it gets too close to the planet.
- Distance of breakup is called the *Roche limit* and is 2.44 planetary radii if object and planet have the same density
- All planetary rings lie near their planet's Roche limit
- Existence of side-by-side ringlets of different compositions indicates rings supplied by varied comets and asteroids
- Objects bonded together chemically will survive Roche limit

# The Roche Limit

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

# Saturn's Moons

- Saturn has several large moons and many more smaller ones
- Like Jupiter, most of the moons form a mini-solar system, but unlike Jupiter, Saturn's moons are of similar densities indicating that they were not heated by Saturn as they formed
- Saturn's moons have a smaller density than those of Jupiter indicating interiors must be mostly ice
- Most moons are inundated with craters, many of which are surrounded by white markings of shattered ice
- The moons also have several surface features that have yet to be explained

# Ice Worlds

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

# Titan

- Saturn's largest moon
- Larger than Mercury
- Mostly nitrogen atmosphere
- Solid surface with liquid oceans of methane
- The Huygens Probe landed on the surface

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

NASA/JPL

# Images from Titan's Surface

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

(c,d): NASA/JPL-Caltech/ASI

# Iapetus

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

(all): NASA/JPL/Space Science Institute

- The side of the moon that faces forward as it orbits Saturn is covered with an extremely dark material.
- Odd ridge circles the satellite.

# Enceladus

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

c: NASA/JPL/Space Science Institute

- The smooth surface seen on Enceladus is the result of water that has erupted from its interior, flooding old craters and drowning them as it freezes.

# Uranus

- Uranus was not discovered until 1781 by Sir William Herschel
- While small relative to Jupiter/Saturn, Uranus is  $4\times$  larger in diameter than Earth and has  $15\times$  the mass
- At 19 AU, Uranus is difficult to study from Earth, but even close up images from Voyager reveal a rather featureless object

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

NASA/JPL

# Atmosphere of Uranus

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

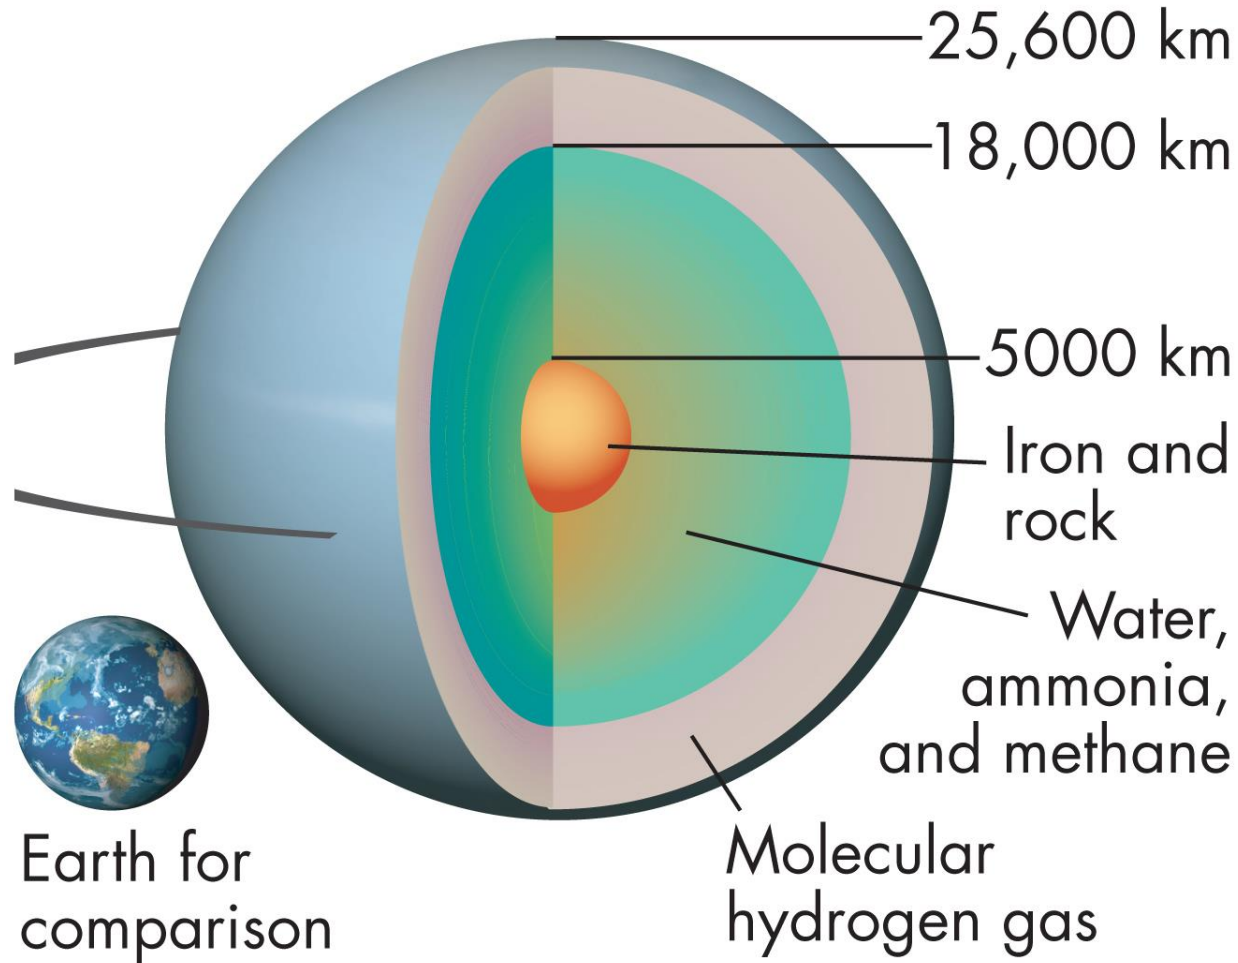

- Atmosphere is rich in hydrogen and methane
- Methane gas and ice are responsible for the blue color of Uranus's atmosphere

# Composition of Uranus

- With a density of  $1.2 \text{ g/cm}^3$  and smaller size, Uranus must contain proportionally fewer light elements than Jupiter/Saturn
- Density is too low for it to contain much rock or iron
- Uranus's interior probably contains water, methane, and ammonia
- Size of equatorial bulge supports the idea that the interior is mostly water and other hydrogen-rich molecules and that it may have a rock/iron core
- It is currently not known if the core formed first and attracted lighter gases that condensed on it, or the core formed by differentiation after the planet formed.

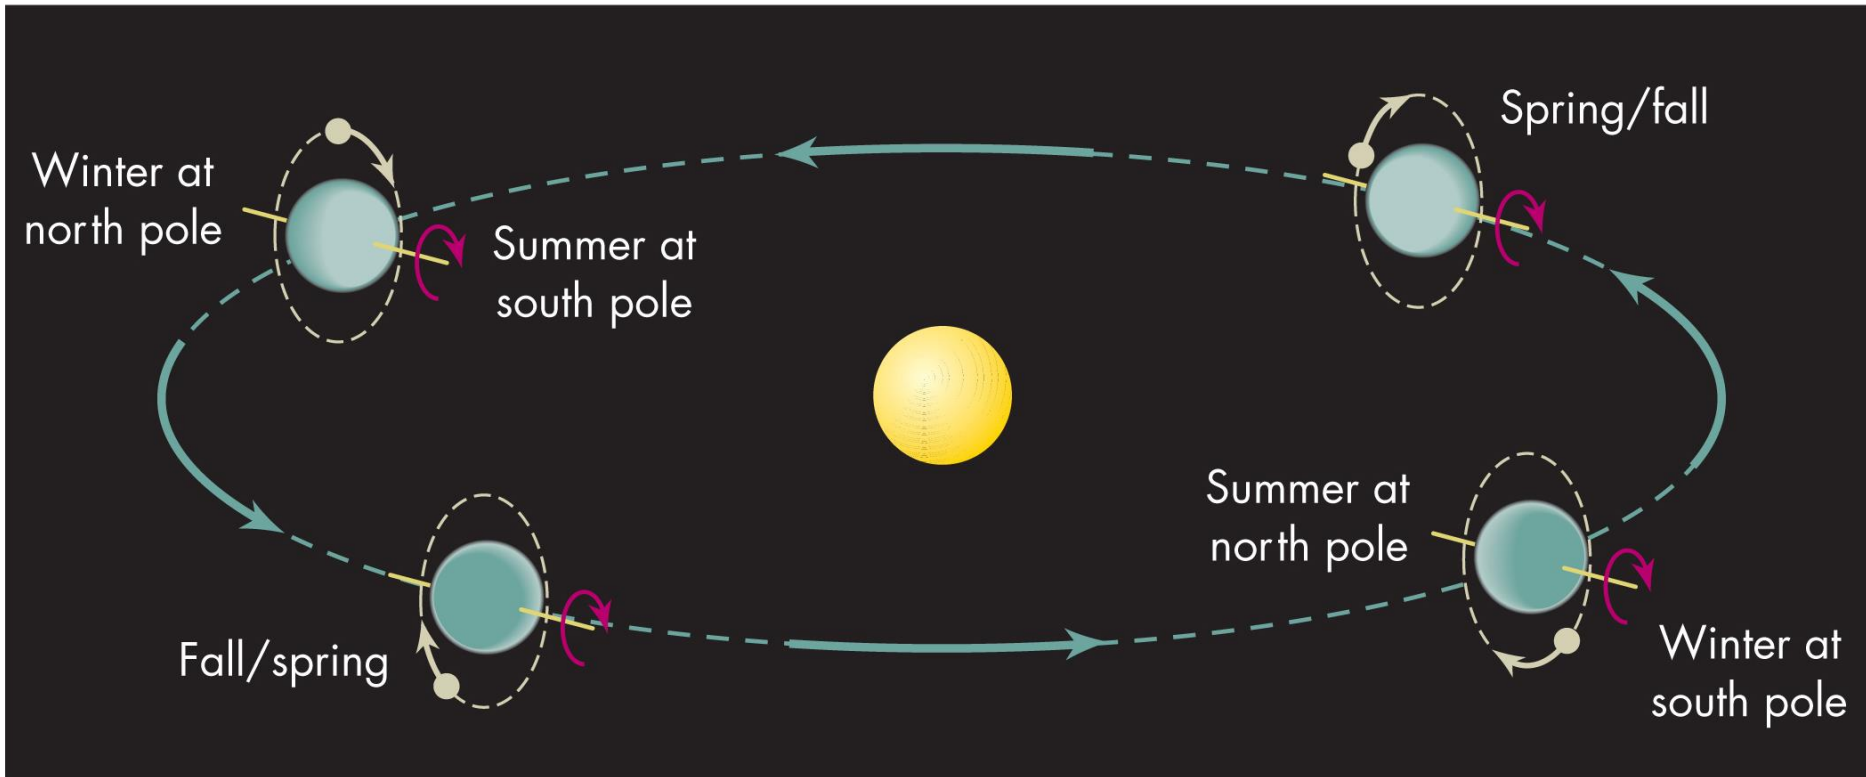

# Interior of Uranus

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

# Uranus's Odd Tilt

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

- Uranus's spin axis is tipped so that it nearly lies in its orbital plane
- The orbits of Uranus's moons are similarly tilted
- Uranus may have been struck during its formation and splashed out material to form the moons, or gravitational forces may have tipped it

# Rings of Uranus

- Uranus is encircled by a set of narrow rings composed of meter-sized objects
- These objects are very dark, implying they are rich in carbon particles or organic-like materials
- The extremely narrow rings may be held in place by *shepherding satellites*

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

NASA/JPL

# Moons of Uranus

- Uranus has 5 large moons and several small ones that form a regular system
- Moons probably composed of ice and rock and many show heavy cratering
- Miranda is very unique in that it appears to have been torn apart and reassembled

# Neptune

- Neptune is similar in size to Uranus
- Deep blue world with cloud bands and vortex structures – the Great “Dark” Spot being, at one time, the most prominent feature
- Neptune was discovered from predictions made by John C. Adams and Urbain Leverrier, who calculated its orbit based on disturbances in Uranus’s orbit

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

Courtesy of NASA/JPL

# Interior of Neptune

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

- Neptune's interior is probably similar to Uranus's – mostly ordinary water surrounded by a thin atmosphere rich in hydrogen and its compounds and probably has a rock/iron core

# Neptune's Atmosphere

- Neptune's blue, like Uranus, comes from methane in its atmosphere
- Unlike Uranus, Neptune has cloud belts
  - Like Jupiter/Saturn, Neptune radiates more energy than it gains from the Sun
  - The deep interior heat source drives convective currents which then lead, via the Coriolis effect, to the visible atmospheric belts

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

Courtesy of NASA/JPL

# Rings of Neptune

Copyright © McGraw-Hill Education. Permission required for reproduction or display.

Courtesy of NASA/JPL

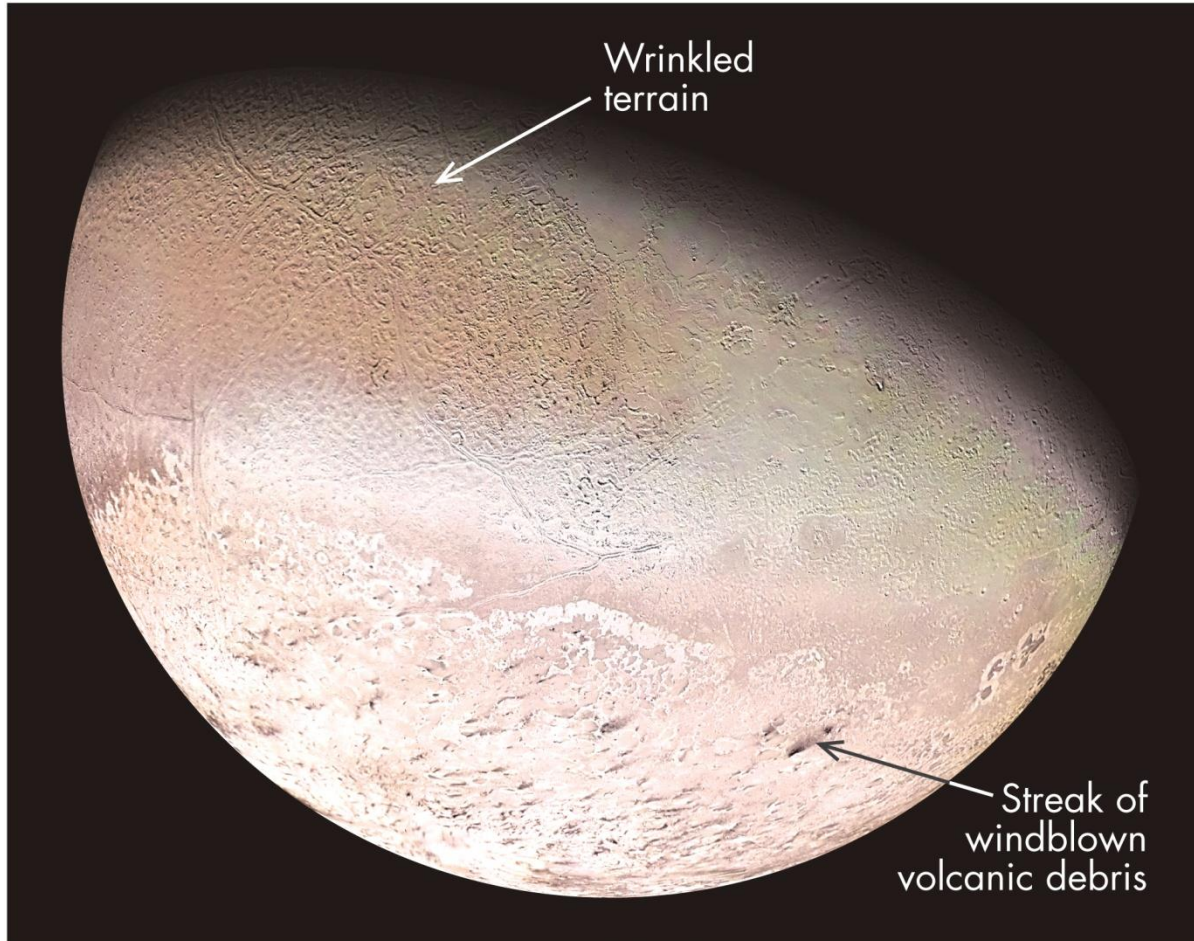

- Neptune, like the other giant planets, has rings
- They are probably debris from satellites or comets that have broken up
- They contain more dust than the Saturn/Uranus rings
- The rings are not distributed uniformly around the ring indicating they are relatively new

# Triton

- Triton's orbit is “backwards” and is highly tilted with respect to Neptune's equator – Triton is perhaps a captured planetesimal from the Kuiper belt
- Triton is large enough and far enough from the planet to retain an atmosphere
- Triton has some craters with dark streaks extending from them – at least one of which originates from a geyser caught in eruption by the passing *Voyager II*
- The material in the geyser is thought to be a mixture of nitrogen, ice, and carbon compounds heated beneath the surface by sunlight until it expands and bursts to the surface

# The Face of Triton
