

Turbomachinery Simulation using STAR-CCM+

Usage From Across the Industry

Outline

Key Objectives

- Conjugate heat transfer
- Aeroelastic response
- Performance mapping

Key Capabilities

- Complex geometry handling
- Conformal polyhedral meshing
- Harmonic balance
- Advanced post-processing

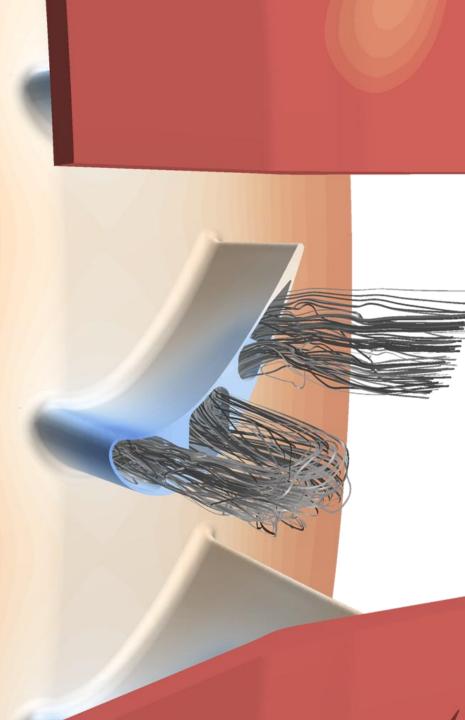

Best Practice

- Mesh requirements
- Solution procedure

Conjugate Heat Transfer

Key Capabilities

- Direct CAD import
- 3D CAD editing
- Meshing
 - Polyhedral cells
 - Conformal interfaces
 - Automatic prism layer generation

Key Capabilities

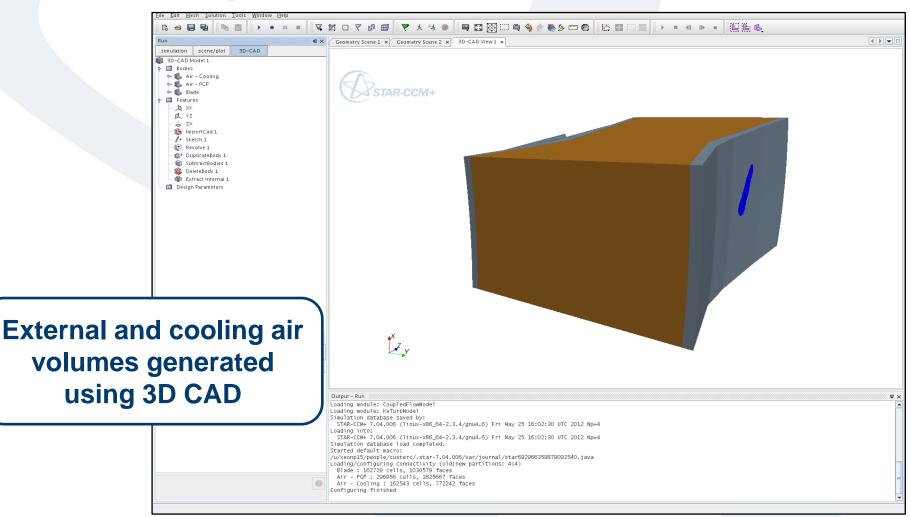

Direct CAD import

Direct import of CAD solid geometry

Key Capabilities

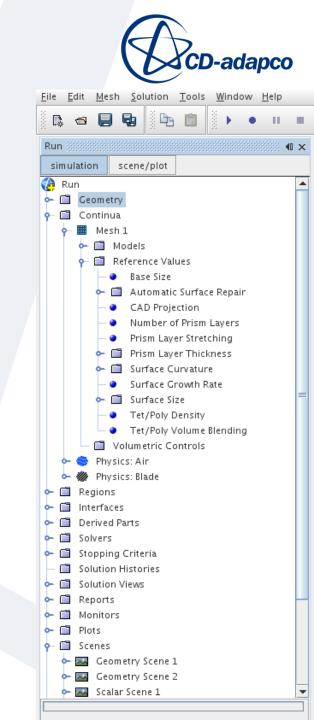

3D CAD editing

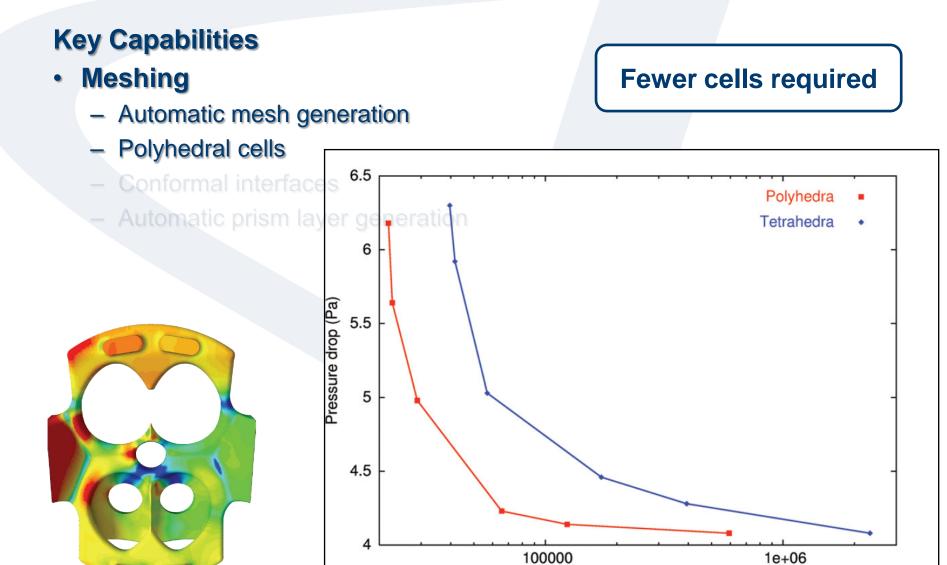

Key Capabilities

- Meshing
 - Automatic mesh generation
 - Polyhedral cells
 - Conformal interfaces
 - Automatic prism layer generation

- Pipelined meshing
- Simple global size settings
- Local refinement control
- Automatic solution interpolation

Number of cells

Cooled Turbine Blade

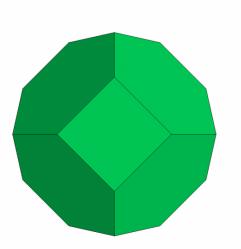

Key Capabilities

- Meshing
 - Automatic mesh generation
 - Polyhedral cells
 - Conformal interfaces
 - Automatic prism layer generation

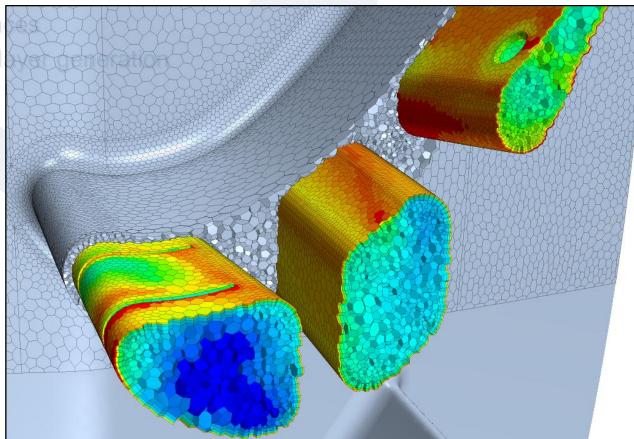

Polyhedral cell faces are orthogonal to the flow regardless of flow direction

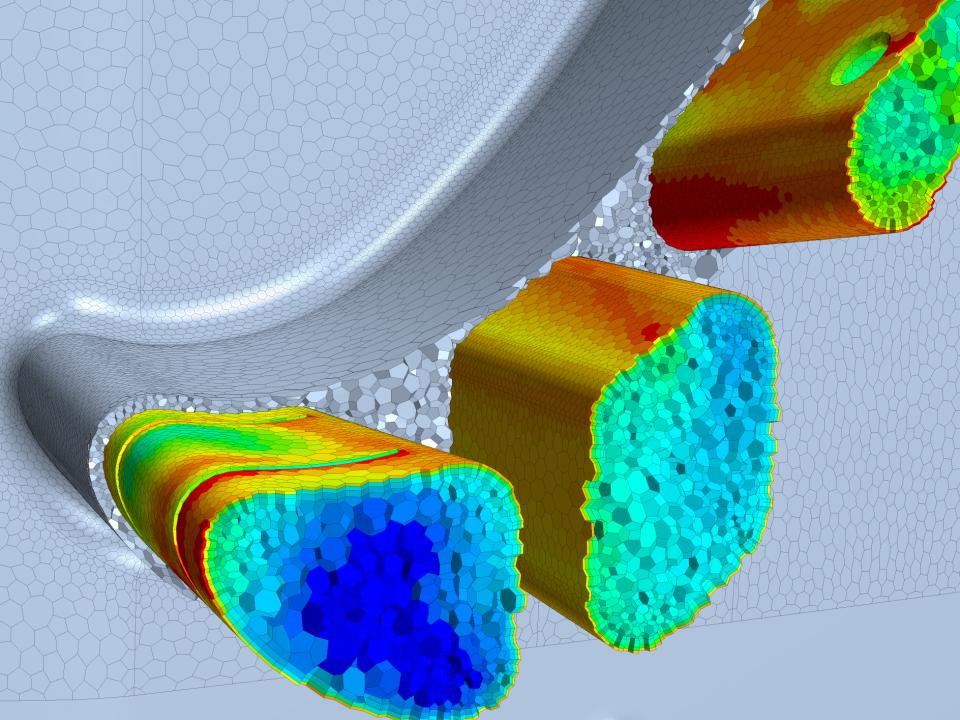

Key Capabilities

- Meshing
 - Automatic mesh generation
 - Polyhedral cells
 - Conformal interfa
 - Automatic prism I

High quality cells, even with complex geometry

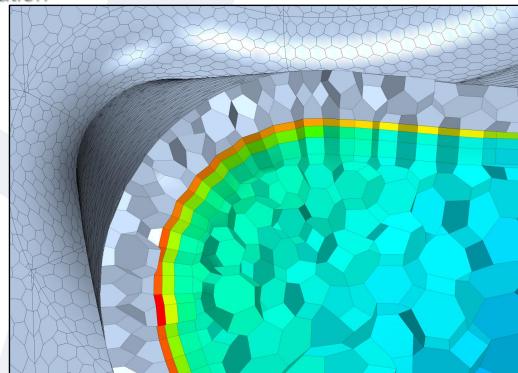

CD-adapco

Key Capabilities

- Meshing
 - Automatic mesh generation
 - Polyhedral cells
 - Conformal interfaces
 - Automatic prism layer generation

Cells are one-to-one connected on the solid/fluid interface

Fluid-side prism layers are automatically generated

Aeroelastic Response

Traditional simulation methods present many challenges

- Aeroelastic analysis must be run unsteady
- Traditional unsteady simulation is challenging
 - Very long run times
 - Must mesh the entire machine
 - Hard to specify blade vibration
 - Hard to extract stability information

- Harmonic balance method in STAR-CCM+ resolves each of these challenges
- The HB method is not available in any other commercial package

Harmonic Balance Basics

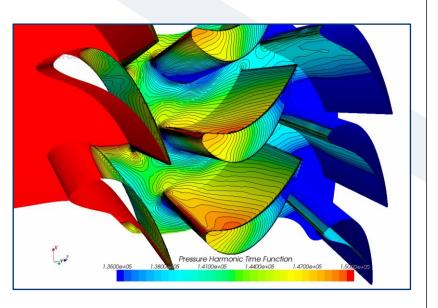

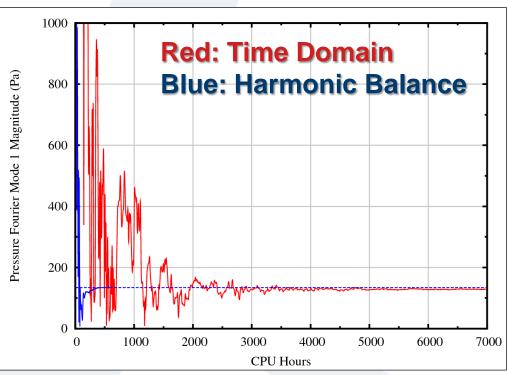

- The harmonic balance method takes advantage of the periodic nature of a turbomachine
- Solves a set of equations that converge to the periodic, unsteady solution
- Full non-linear solver
- All unsteady interactions captured

Rapid calculation of unsteady solution

- Unsteady simulation must be run for many time steps to converge
- HB simulation converges to the unsteady solution 10x faster

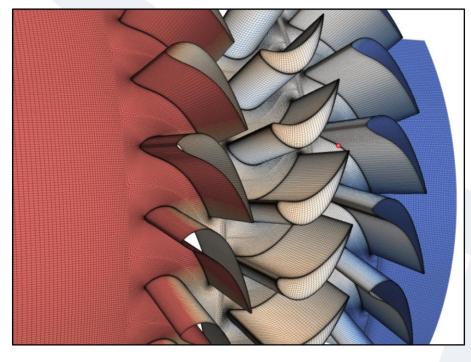

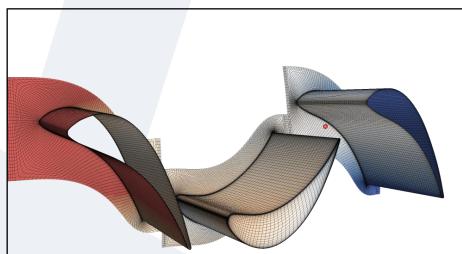

Single blade passage mesh

- All blades must be meshed for an unsteady simulation
- Only one blade passage must be meshed for a HB simulation, however the solution is calculated for all blades

Harmonic Balance

Time Domain

Specify blade vibration

- The vibration of each blade is staggered. This is known as the "Interblade phase angle"
- To determine stability a simulation must be run for each phase angle
- Traditional unsteady solvers require manual set up of motion for each phase angle

Specify blade vibration

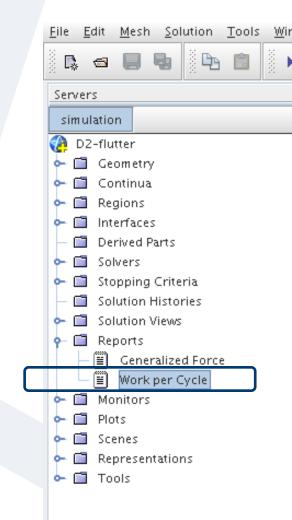

> Interblade phase angle is a simple input to the HB solver

Flutter Parameters - Properties 🎆		₹×
o Properties		
Flutter Frequency	5000.0 radian/s	
Flutter Phase Angle	180.0 deg	
Modes	1	

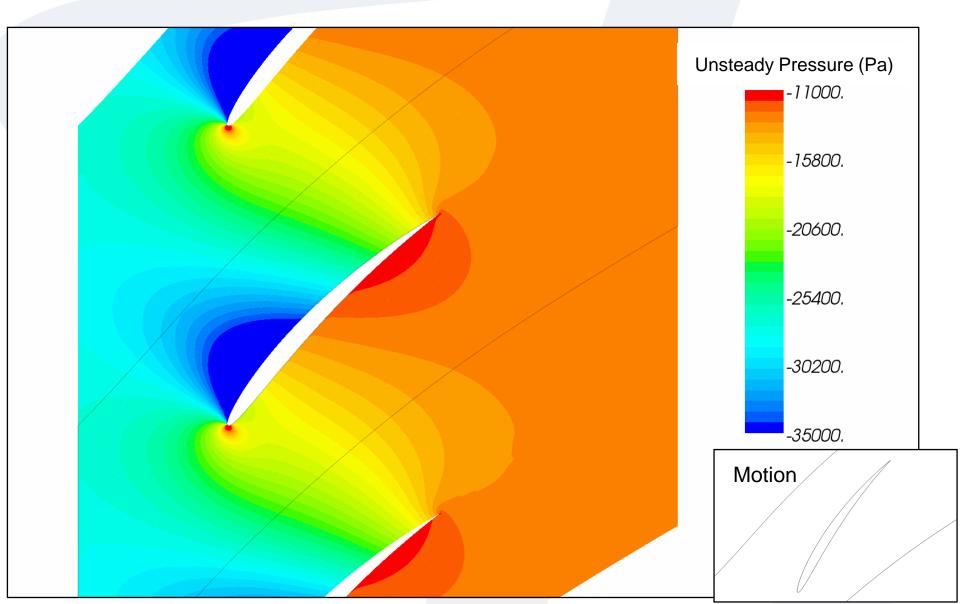

Work per cycle calculation

- Stability is determined by "Work per cycle"
- Traditional unsteady solver requires the solution be saved at each time step and complex, external post processing to determine this value
- Work per cycle is a simple report when using the HB solver

Example: Vane Flutter

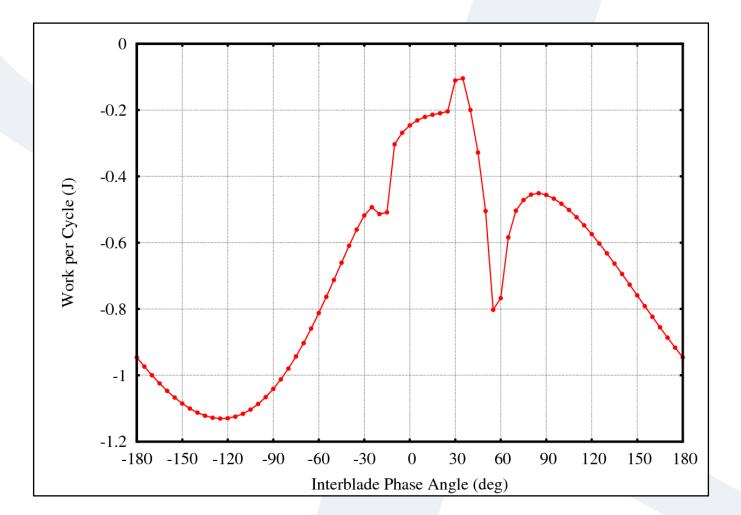

Example: Vane Flutter

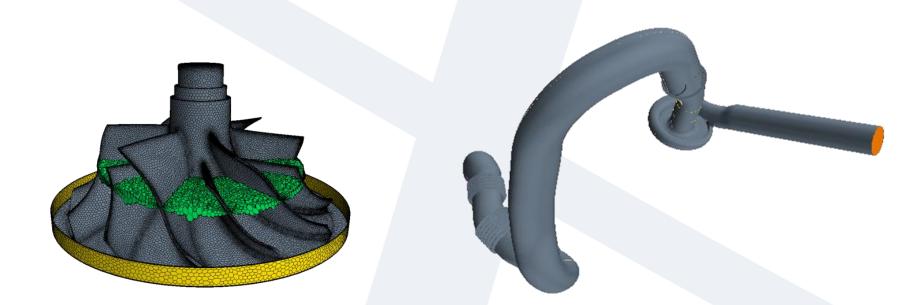

Work per cycle map shows this vane will not flutter

CD-adapco

Key Benefits

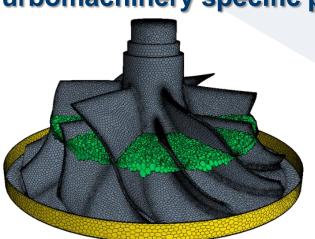

- Complex geometry handling
- Polyhedral cells
- High quality mesh
- Prism layer generation
- Harmonic balance solver

CD-adapco

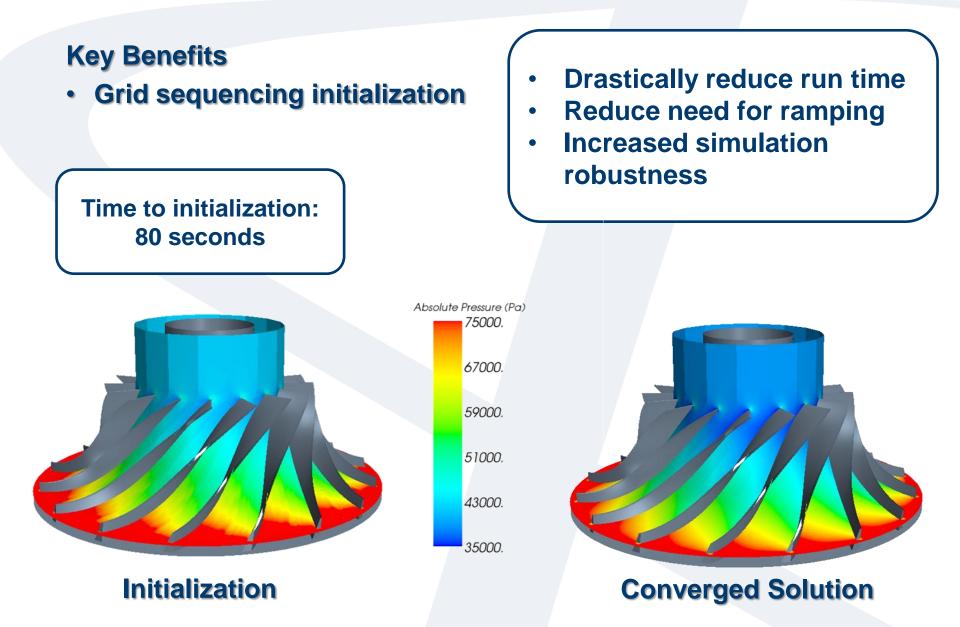

Key Benefits

- Complex geometry handling
- Polyhedral cells
- High quality mesh
- Prism layer generation
- Harmonic balance solver
- Grid sequencing initialization
- Efficiency optimization with Optimate+
- Turbomachinery specific post-processing

Key Benefits

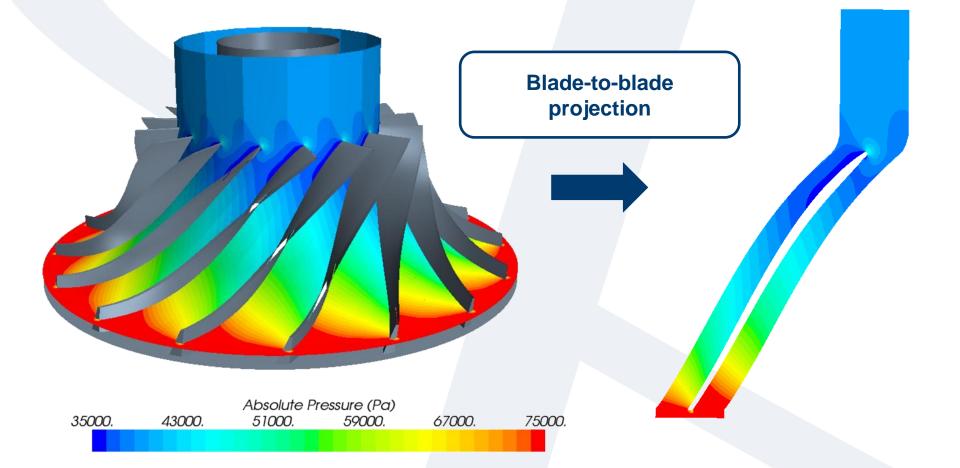

Efficiency optimization with Optimate+

Optimate v7.04.004

Optimization using SHERPA	
Pareto Optimization using MO-SHERPA	
Design of Experiment	
Robustness	0.401132 0.525962 15.2721 0.349417 0.08 0.12

Key Benefits

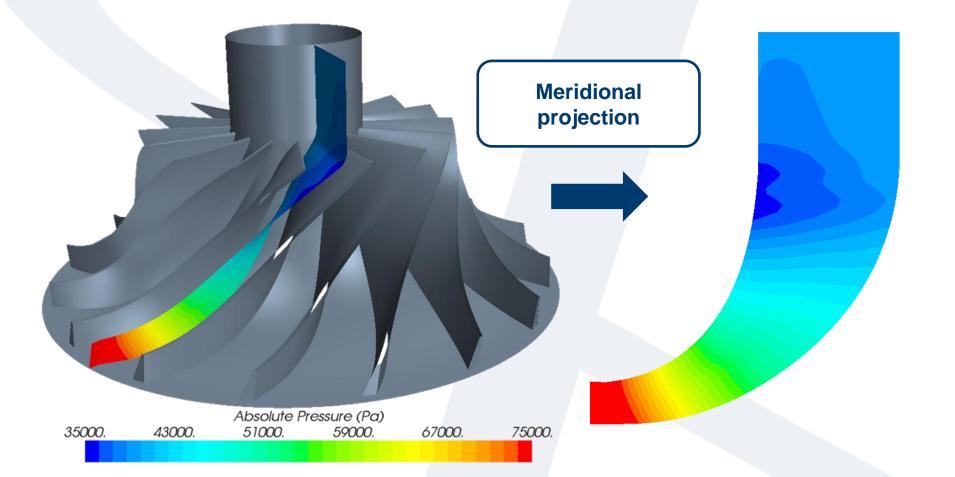

Turbomachinery specific post-processing

Key Benefits

Turbomachinery specific post-processing

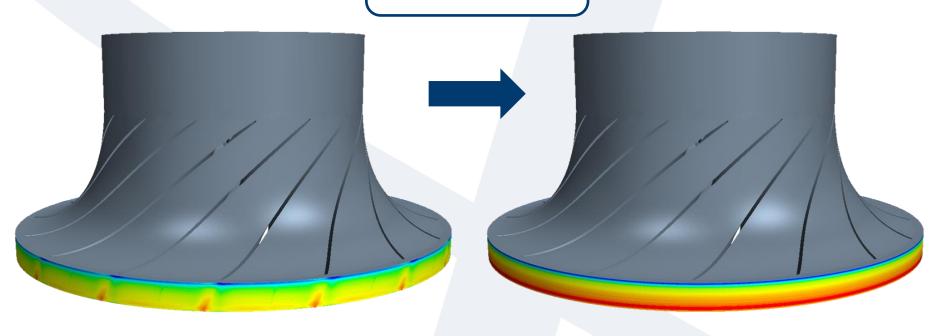

Key Benefits

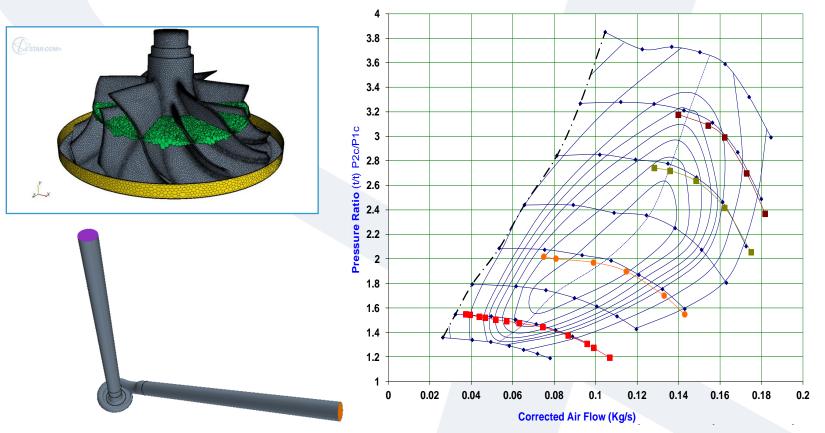

Turbomachinery specific post-processing

Circumferential Averaging

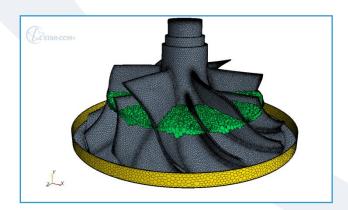

Absolute Pressure (Pa) 78000. 78800. 79600. 80400. 81200. 82000. Validated Simulation: Radial Compressor

- Comparison with rig measurements
 - Full performance curve
 - RPM range

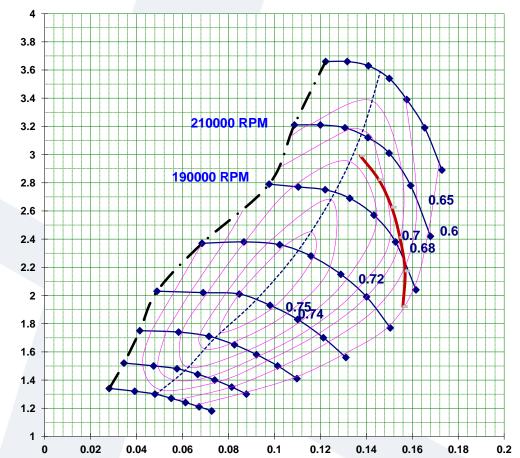

Validated Simulation: Radial Compressor

- Installation effects
 - Curved inlet duct
 - Diffuser outlet

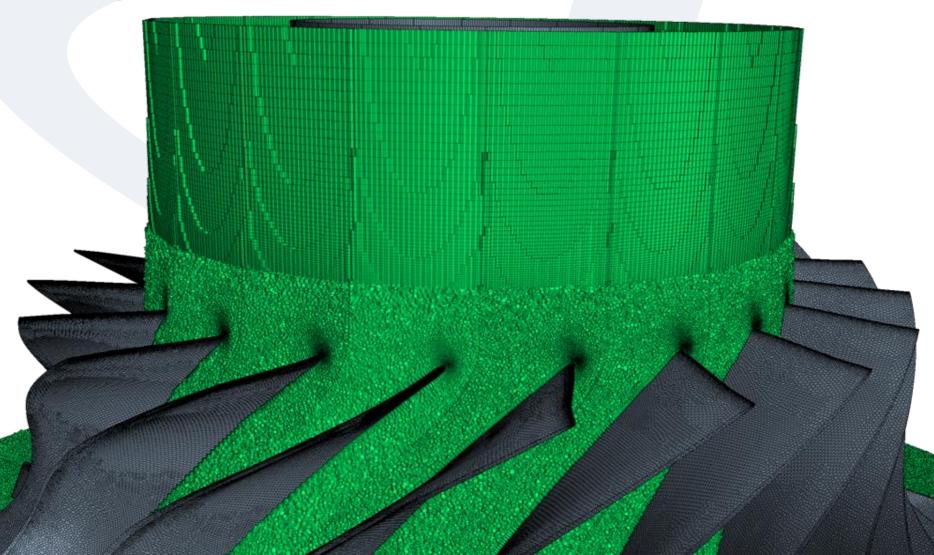

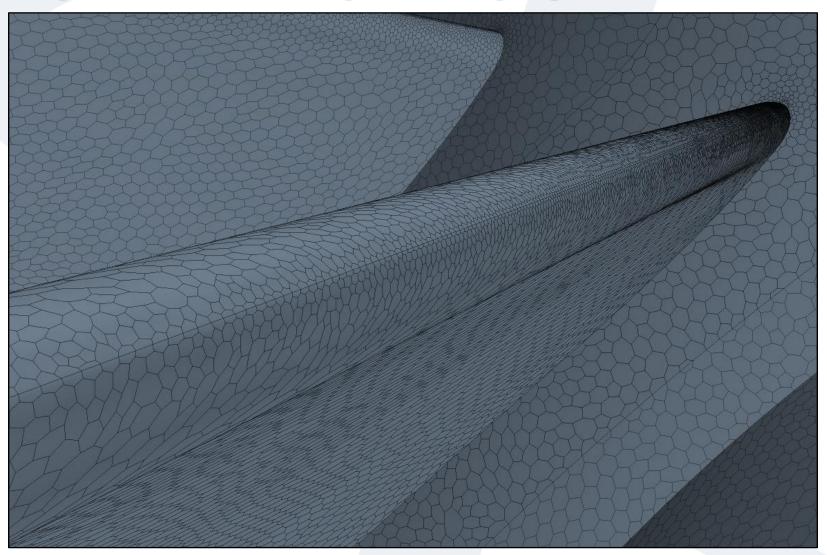

Polyhedral mesh with extruded inlet/exit as needed

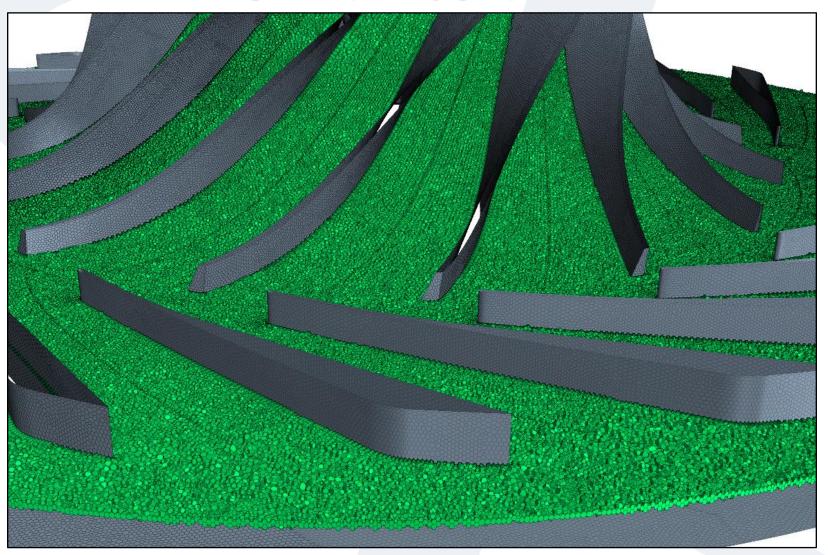

High resolution of leading and trailing edges

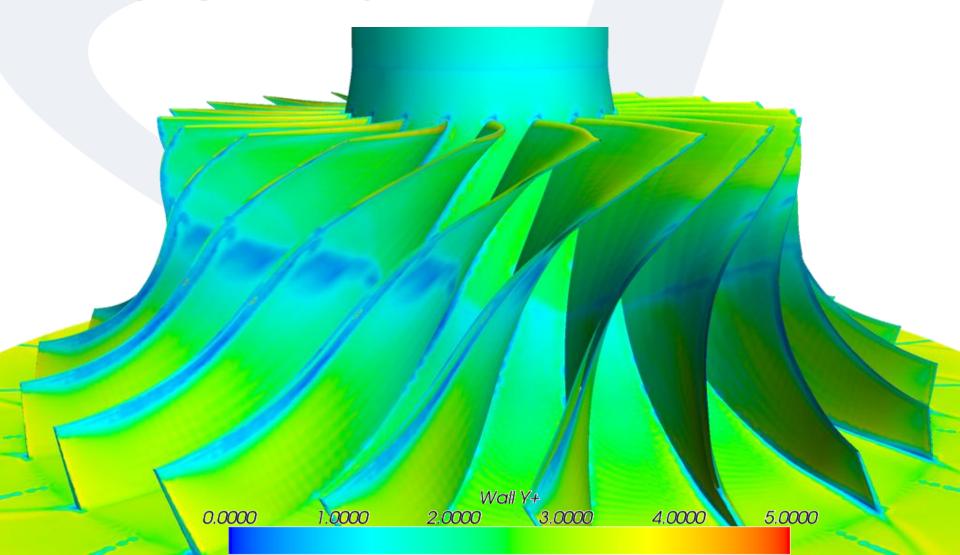

Uniform cell sizing in the primary gas path

All y+ algorithm with y+ values less than 5

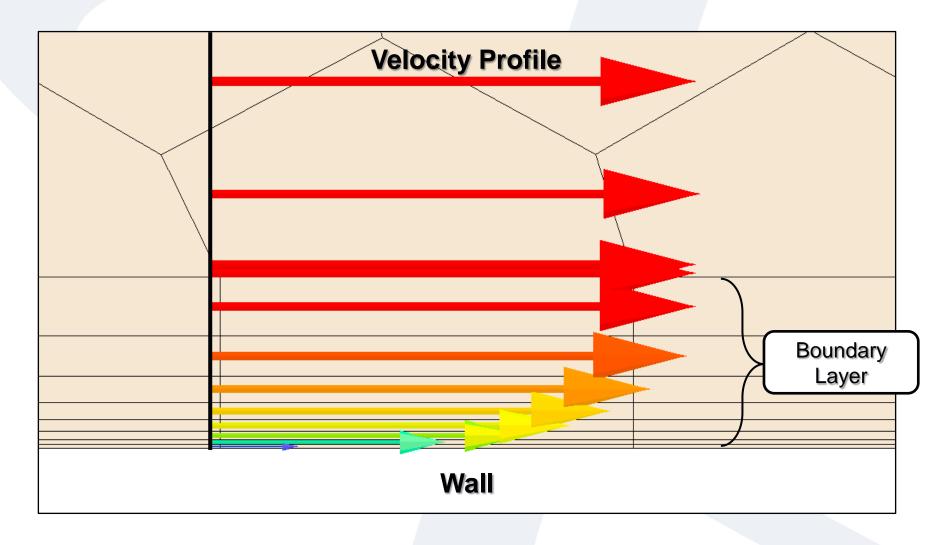

Last prism layer similar size to the first poly cell layer

Prism Layer Cells

Polyhedral Cells

At least 5 prism layers to resolve the boundary layer

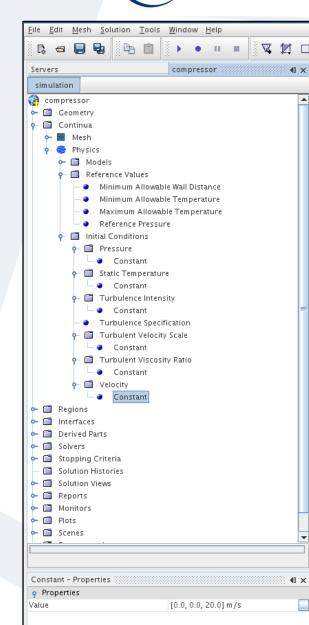

Turbomachinery Solution Guidelines

Reference Values

 Set reference pressure to be near the operating point

Initial Conditions

- Set velocity to a non-zero value
- Set initial pressure to the inlet or exit value, whichever is greater
- Set temperature the inlet value

Turbomachinery Solution Guidelines

Initialization

- Use grid sequencing initialization to obtain an initial condition
- Ensure that each grid level converges
- Initialize solution using actual operating conditions (do not ramp boundary conditions or rotation rate)

Suggested GSI parameters

- Max iterations per level: 200
- Convergence tolerance: 0.005
- CFL number: 20

Turbomachinery Solution Guidelines

Solver Settings

- Use a high CFL number whenever possible, a CFL number of 20 is a good starting point
- For cases with high and low speed flow regions, enable Continuity Convergence Acceleration
