

Ultra-thin base materials take PCB miniaturisation to the next level

Flexible and rigid ultra-thin base materials enable highly reliable, thinner PCBs

AUTHOR Daniel Schulze

SUMMARY

New approaches are needed to meet the increasing demand for smaller and thinner electronic devices. Both rigid and flexible ultra-thin base materials for PCBs can fill this need by enabling higher-density designs with enhanced miniaturization in the Z direction, leaving more space for other components or reducing the overall thickness of the device. Because these materials require specific design approaches and fabrication technology, it's important to collaborate with a PCB manufacturer that has advanced engineering services to ensure a PCB design that is compact, cost-effective and reliable.

Almost all markets are experiencing increasing demand for smaller and thinner electronic devices. Today's mobile devices are small enough to fit in a watch, and the aerospace and automotive industries desire smaller and lighter devices to lower fuel costs and reduce emissions. Likewise, the medical industry needs wearable sensors, implantable devices, and handheld instruments that are small and lightweight.

Manufacturers of the printed circuit boards (PCBs) that are at the heart of these electronic devices have been making them more compact and lighter primarily by decreasing the size of the copper features and board materials. Extremely thin base materials are making it possible to take miniaturization beyond what was previously possible without compromising reliability or performance.

Thinner substrates

Although a great deal of miniaturization can be achieved in the X and Y directions, the technology is beginning to reach its limits. Another level of compactness is possible by using rigid and flexible ultra-thin base materials to make highly reliable PCBs that are thinner. While miniaturization in X / Y direction can greatly reduce the footprint of PCBs, miniaturization in the Z direction leaves more space for other components or reduces the overall thickness of the device.

Figure 1. Evolution of pacemakers

With thinner base materials, less plated copper is needed to fill via connections. This automatically results in thinner copper layers and, therefore, lines/spaces with smaller resolutions and a reduced interconnect footprint.

Flex systems

Medical devices, like hearing aids and active implants, often require PCBs that can fit into the smallest area possible to improve the patients' comfort. With flexible substrates, it is possible to create PCBs that fold to reduce the surface area and volume needed to house the PCB and thus increase the integration density. Using thinner flex materials rather than traditional thick flex materials can reduce the space needed for the PCB even more. For example, a six-layer flex system is about half the thickness of a system fabricated with standard flexible materials.

Figure 2. 6-layer stack-up with standard flex material compared to 6-layer stack-up with ultra-thin base material

Flex systems are used in hearing aids to ensure all the necessary electrical components can be housed within a package that fits in the ear canal. In this case, the circuit board is assembled flat with the integrated circuits, resistors, and

capacitors and then folded to reduce the overall footprint.

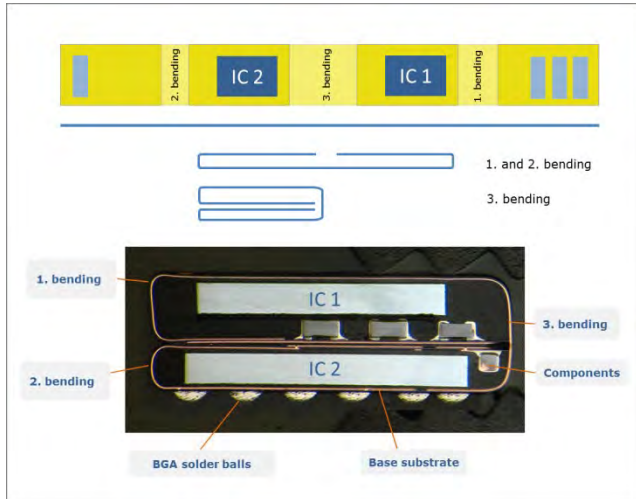

Figure 3. From flat substrate to folded package

Ultra-thin flexible substrates also allow better bending. This means the PCBs can be bent with smaller bend radii to achieve even smaller volumes. A comparison is shown in Table 1. The improved bending makes ultra-thin flexible materials ideal for making cables that require dynamic bending, as in robotic arms.

	TOTAL THICKNESS	MIN BEND RADIUS
Standard 6-layer	397 μm	2.38 mm
Ultra-thin 6-layer	172 μm	1.03 mm

Table 1. Comparison of minimum bend radii according to IPC-2223 5.2.4. (6x total thickness PCB)

Today, the outer layers of a multilayer flex system typically measure 12 μm for the polyimide and 12 μm for the adhesive. The new FRCC material provided by DYCONEX offers 3- or 5-μm thick polyimide outer layers combined with a minimum 17 μm thick adhesive layer.

Figure 4. Cu clad polyimide laminate

	THICKNESS (μm)
Copper	12
Polyimide (PI)	3, 5
Adhesive (Adh)	17, 20, 25, 28

PROPERTIES	UNIT	PI	ADH
Dielectric constant (1 GHz)	--	3.3	3.0
Dissipation factor (1 GHz)	--	0.01	0.019
Surface resistivity	MΩ	3x10 ⁸	
Volume resistivity	Ω*cm	1x10 ⁸	
Insulation resistance	MΩ	1x10 ³	
Dielectric strength	kV/mil	2	n/a
Peel strength (initial/aging)	kN/m	0.8	
Youngs modulus	GPa	4	1
CTE (XY)	ppm/K	25	80, 580
CTE (Z)	ppm/K	n/a	210
Glass transition temp. Tg (DMA)	°C	320	70, 210
Moisture absorption (23°C, 24h)	%	1.0	
Flammability	--	VTM-0

Rigid systems

For applications that require a 2D PCB, ultra-thin rigid materials are available. These are typically used as packaging substrates for ICs, where they help make the entire component very thin. For example, a 6-layer rigid system using an ultra-thin material is about 260 µm thick, the same system with standard material is 512 microns thick. With the ultra-thin rigid materials, it is possible to achieve pitches smaller than 175 microns, lines or spaces 25 microns wide, via diameters of 50 microns, and pad diameters of 100 microns.

	Standard material	Ultra-thin material
Thickness of rigid 6-layer system	512 µm	260 µm
Lines / Spaces	50 – 70 µm	30 – 50 µm
Via diameter	75 µm	50 µm
Pad diameter	150 µm	100 µm
Pitch	250 µm	175 µm

Table 3. Comparison of design features for 6-layer systems

Figure 6. 6-layer stack-up with standard rigid material compared to 6-layer stack-up with ultra-thin base material

Figure 7. 6-layer rigid stack-up with ultra-thin materials

The coefficient of thermal expansion of the rigid substrate is one of the most important properties for chip packaging substrates. If it is not matched well with the silicon die, it can lead to cracks that adversely affect packaging production and the assembly of the components onto the substrate. Problems with thermal expansion can even lead to failures during device use. Ultra-thin substrate materials also need to have very good high-frequency properties to achieve the requirements of today's high-speed telecom applications.

PROPERTIES	UNIT	CONDITIONS	VALUE
CTE	ppm/°C	XY < Tg	5-6
	ppm/°C	Z < Tg	18-22
Tg	°C	DMA	280-300
Flexural modulus	GPa	25°C	32
Dielectric constant	ϵ_r	1 GHz	4.4
	ϵ_r	10 GHz	4.3
Dissipation factor	--	1 GHz	0.006
	--	10 GHz	0.008
Dielectric strength	kV/mm	ASTM D149 Method A	103
Moisture absorption	%		0.3
Min thickness core	μm		30
Min thickness prepreg	μm		20

Considerations for ultra-thin materials

Because ultra-thin materials require specific design approaches, fabrication technology, and other considerations, it is critical to use an experienced PCB manufacturer with advanced engineering services.

Advanced techniques such as laser direct imaging can be used with ultra-thin materials, but highly precise registration processes are required because the features are typically smaller when a thinner material is used.

It's important to note that the thinner material can lead to warpage and increased flexibility, which make proper handling during assembly more critical than with traditional materials. The reduced dimensions and smaller pads require higher accuracy during assembly, and when thinner materials are used, it can also be more difficult to place the finalized circuits into

the end application without breaking them. Because of these challenges, it is critical to have early discussions with the PCB manufacturer regarding handling requirements and the number of units within a delivery panel.

The additional handling and fixtures needed with ultra-thin flex materials increase assembly and handling costs. However, lower process and material costs can help balance these. Material costs are reduced as less copper is required. Consulting with the engineering team of the PCB manufacturer during the design phase can help ensure the most cost-effective solution that meets the performance needs of the specific application.

Assuring quality and reliability

The reliability of the interconnect structure improves with thinner stack-ups when using ultra-thin materials. Smaller expansion along the Z axis results in less stress for vias during temperature cycles.

DYCONEX has created a center of competence for product reliability. This testing laboratory unifies all the processes necessary for precise monitoring of product reliability. The equipment includes stations for electrical fault isolation and thermography as well as multiple interconnect stress test (IST) units, bending testers, a soldering simulation oven, and instruments for thermomechanical and dynamic mechanical analysis (TMA, DMA). Furthermore, a scanning electron microscope and various optical microscopes can be used for investigations.

For critical medical or aerospace applications, the laboratory has developed extensive and systematic methodologies that make it possible to gather solid evidence about product reliability by employing accelerated test procedures such as the IST test. In IST tests, special test coupons that include vias are subjected to temperature cycles, after which they are measured for possible changes in resistance within the test coupon. Any corresponding increase in resistance is indicative of damage.

Conclusion

Ultra-thin PCB base materials are suitable for all markets where miniaturization and high reliability play a role. They can enable miniaturization with increased functionality through higher-density designs. Thinner material leads to smaller vias, reduced aspect ratio of vias, smaller lines and spaces, less copper plating, and better fill grades, but it can also increase handling complexity. Working with a PCB manufacturer that offers advanced engineering services can help ensure your design is compact while remaining cost-effective and reliable.

About DYCONEX

DYCONEX, a company of the Micro Systems Technologies (MST) group, has more than 50 years of experience in manufacturing highly complex flexible, rigid-flex, and rigid high-density interconnect/microvia printed circuit boards for applications where miniaturization, increased functionality, quality, and reliability are critical. DYCONEX supplies complex circuit boards, LCP and chip substrate solutions to leading manufacturers around the world in the areas of medical technology, space and aviation, industrial electronics, telecommunications, and semiconductor technology. During the design phase, DYCONEX offers a variety of services to help clients develop the optimal solution for their application with an eye toward the best manufacturing processes.

About the Author

Daniel Schulze has studied at the Technical University of Dresden and holds a diploma in electrical engineering. During his diploma thesis and an internship at the Georgia Tech Packaging Research Center, he got involved with working on optical waveguides embedded in PCBs. In 2005, he began as product engineer at DYCONEX AG. Since 2008, he has been an engineering manager at DYCONEX and is responsible for the product development of PCBs used in medical imaging, hearing aids, cochlear implants, industrial, and HF applications.
