

Vitamin B₁₂ Deficiency: Recognition and Management

ROBERT C. LANGAN, MD, FAAFP, and ANDREW J. GOODBRED, MD, *St. Luke's Family Medicine Residency Program, Bethlehem, Pennsylvania*

Vitamin B₁₂ deficiency is a common cause of megaloblastic anemia, various neuropsychiatric symptoms, and other clinical manifestations. Screening average-risk adults for vitamin B₁₂ deficiency is not recommended. Screening may be warranted in patients with one or more risk factors, such as gastric or small intestine resections, inflammatory bowel disease, use of metformin for more than four months, use of proton pump inhibitors or histamine H₂ blockers for more than 12 months, vegans or strict vegetarians, and adults older than 75 years. Initial laboratory assessment should include a complete blood count and serum vitamin B₁₂ level. Measurement of serum methylmalonic acid should be used to confirm deficiency in asymptomatic high-risk patients with low-normal levels of vitamin B₁₂. Oral administration of high-dose vitamin B₁₂ (1 to 2 mg daily) is as effective as intramuscular administration for correcting anemia and neurologic symptoms. Intramuscular therapy leads to more rapid improvement and should be considered in patients with severe deficiency or severe neurologic symptoms. Absorption rates improve with supplementation; therefore, patients older than 50 years and vegans or strict vegetarians should consume foods fortified with vitamin B₁₂ or take vitamin B₁₂ supplements. Patients who have had bariatric surgery should receive 1 mg of oral vitamin B₁₂ per day indefinitely. Use of vitamin B₁₂ in patients with elevated serum homocysteine levels and cardiovascular disease does not reduce the risk of myocardial infarction or stroke, or alter cognitive decline. ► **Patient information:** A handout on this topic is available at <https://familydoctor.org/vitamin-b-12>.

Vitamin B₁₂ (cobalamin) is a water-soluble vitamin obtained through the ingestion of fish, meat, and dairy products, as well as fortified cereals and supplements.^{1,2} It is coabsorbed with intrinsic factor, a product of the stomach's parietal cells, in the terminal ileum after being extracted by gastric acid^{1,2} (*Figure 1*³). Vitamin B₁₂ is crucial for neurologic function, red blood cell production, and DNA synthesis, and is a cofactor for three major reactions: the conversion of methylmalonic acid to succinyl coenzyme A; the conversion of homocysteine to methionine; and the conversion of 5-methyltetrahydrofolate to tetrahydrofolate.^{1,2}

In the United States and the United Kingdom, the prevalence of vitamin B₁₂ deficiency is approximately 6% in persons younger than 60 years, and nearly 20% in those older than 60 years.¹ Latin American countries have a clinical or subclinical deficiency rate of approximately 40%.¹ The prevalence is 70% in Kenyan school children, 80% in East Indian preschool-aged children, and 70% in East Indian adults.¹ Certain risk factors

increase the prevalence of vitamin B₁₂ deficiency (*Table 1*).^{4,5} Dietary insufficiency, pernicious anemia (i.e., an autoimmune process that reduces available intrinsic factor and subsequent absorption of vitamin B₁₂^{1,2,6,7}), and long-term use of metformin or acid-suppressing medications have been implicated in B₁₂ deficiency.^{8,9}

A multicenter randomized controlled trial of 390 patients with diabetes mellitus showed that those taking 850 mg of metformin three times per day had an increased risk of vitamin B₁₂ deficiency (number needed to harm = 14 per 4.3 years) and low vitamin B₁₂ levels (number needed to harm = 9 per 4.3 years) vs. placebo.⁸ This effect increased with duration of therapy, and patients had an unclear prophylactic supplementation response.⁸ A case-control study that compared 25,956 patients who had vitamin B₁₂ deficiency with 184,199 control patients found a significantly increased risk of vitamin B₁₂ deficiency in patients who had taken proton pump inhibitors (odds ratio = 1.65) or histamine H₂ blockers (odds ratio = 1.25) for at least two years.⁹ In light of these findings, long-term

use of these medications should be periodically reassessed, particularly in patients with other risk factors for vitamin B₁₂ deficiency.^{8,9}

Manifestations

Vitamin B₁₂ deficiency affects multiple systems, and sequelae vary in severity from mild fatigue to severe neurologic impairment^{1,2,6,10} (Table 2^{4,10}). The substantial hepatic storage of vitamin B₁₂ can delay clinical manifestations for up to 10 years after the onset of deficiency.¹¹ Bone marrow suppression is common and potentially affects all cell lines, with megaloblastic anemia being most common.^{1,2,6} The resultant abnormal erythropoiesis can trigger other notable abnormal laboratory findings, such as decreased haptoglobin levels, high lactate dehydrogenase levels, and elevated reticulocyte count.^{1,2,6} Symptoms typically include being easily fatigued with exertion, palpitations, and skin pallor.^{1,2,6} Skin hyperpigmentation, glossitis, and infertility have also been reported.^{1,2,6} Neurologic manifestations

are caused by progressive demyelination and can include peripheral neuropathy, areflexia, and the loss of proprioception and vibratory sense. Areflexia can be permanent if neuronal death occurs in the posterior and lateral spinal cord tracts.^{1,2,6,12} Dementia-like disease, including episodes of psychosis, is possible with more severe and chronic deficiency.^{1,12} Clinical evaluation seems to show an inverse relationship between the severity of megaloblastic anemia and the degree of neurologic impairment.²

Maternal vitamin B₁₂ deficiency during pregnancy or while breastfeeding may lead to neural tube defects, developmental delay, failure to thrive, hypotonia, ataxia, and anemia.^{4,13-16} Women at high risk or with known deficiency should supplement with vitamin B₁₂ during pregnancy or while breastfeeding.^{4,14-16}

Screening and Diagnosis

Screening persons at average risk of vitamin B₁₂ deficiency is not recommended.¹⁷ Screening should be considered in patients

Table 1. Risk Factors for Vitamin B₁₂ Deficiency

Decreased ileal absorption

Crohn disease
Ileal resection
Tapeworm infection

Decreased intrinsic factor

Atrophic gastritis
Pernicious anemia
Postgastrectomy syndrome (includes Roux-en-Y gastric bypass)

Genetic

Transcobalamin II deficiency

Inadequate intake

Alcohol abuse
Patients older than 75 years
Vegans or strict vegetarians (including exclusively breastfed infants of vegetarian/vegan mothers)

Prolonged medication use

Histamine H₂ blocker use for more than 12 months
Metformin use for more than four months
Proton pump inhibitor use for more than 12 months

with risk factors, and diagnostic testing should be considered in those with suspected clinical manifestations.^{1,2,6,18}

The recommended laboratory evaluation for patients with suspected vitamin B₁₂ deficiency includes a complete blood count and serum vitamin B₁₂ level.^{2,19-21} A level of less than 150 pg per mL (111 pmol per L) is diagnostic for deficiency.^{1,2} Serum vitamin B₁₂ levels may be artificially elevated in patients with alcoholism, liver disease, or cancer because of decreased hepatic clearance of transport proteins and resultant higher circulating levels of vitamin B₁₂; physicians should use caution when interpreting laboratory results in these patients.^{22,23} In patients with a normal or low-normal serum vitamin B₁₂ level, complete blood count results demonstrating macrocytosis, or suspected clinical manifestations, a serum methylmalonic acid level is an appropriate next step^{1,2,6,18} and is a more direct measure of vitamin B₁₂'s physiologic activity.^{1,2} Although not clinically validated or available for widespread use, measurement of holotranscobalamin, the metabolically

active form of vitamin B₁₂, is an emerging method of detecting deficiency.^{1,2,18} Table 3 lists the relative sensitivities and specificities of various laboratory tests.²⁴

Pernicious anemia refers to one of the hematologic manifestations of chronic autoimmune gastritis, in which the immune system targets the parietal cells of the stomach or intrinsic factor itself, leading to decreased

Table 3. Estimated Sensitivity and Specificity of Serum Laboratory Tests for Vitamin B₁₂ Deficiency

Criteria	Sensitivity (%)	Specificity
Decreased serum vitamin B ₁₂ level (< 200 pg per mL [148 pmol per L])	95 to 97	Uncertain
Elevated serum methylmalonic acid level	> 95	Uncertain

absorption of vitamin B₁₂.¹ Asymptomatic autoimmune gastritis likely precedes gastric atrophy by 10 to 20 years, followed by the onset of iron-deficiency anemia that occurs as early as 20 years before vitamin B₁₂-deficiency pernicious anemia.²⁵

Patients diagnosed with vitamin B₁₂ deficiency whose history and physical examination do not suggest an obvious dietary or malabsorptive etiology should be tested for pernicious anemia with anti-intrinsic factor antibodies (positive predictive value = 95%), particularly if other autoimmune disorders are present.^{1,2,6,18} Patients with pernicious anemia may have hematologic findings consistent with normocytic anemia.¹ If anti-intrinsic factor results are negative but suspicion for pernicious anemia remains, an elevated serum gastrin level is consistent with the diagnosis.² The Schilling test, which was once the diagnostic standard for pernicious anemia, is no longer available in the United States. *Figure 2* presents an approach to diagnosing vitamin B₁₂ deficiency and pernicious anemia.^{18,26}

Treatment

Vitamin B₁₂ deficiency can be treated with intramuscular injections of cyanocobalamin or oral vitamin B₁₂ therapy. Approximately 10% of the standard injectable dose of 1 mg is absorbed, which allows for rapid replacement in patients with severe deficiency or severe neurologic symptoms.² Guidelines from the British Society for Haematology recommend injections three times per week for two weeks in patients without neurologic deficits.¹⁸ If neurologic deficits are present, injections should be given every other day for up to three weeks or until no further improvement is noted. *Table 4* lists the usual times until improvement for abnormalities associated with vitamin B₁₂ deficiency.²⁷ In general, patients with an irreversible cause should be treated indefinitely, whereas those with a reversible cause should be treated until the deficiency is corrected and symptoms resolve.¹ If vitamin B₁₂ deficiency coexists with folate deficiency, vitamin B₁₂ should be replaced first to prevent subacute combined degeneration of the spinal cord.¹ The British Society for

Evaluation of Suspected Vitamin B₁₂ Deficiency

*—Indications include alcohol abuse, gastric bypass surgery, histamine H₂ blocker use for more than 12 months, inflammatory bowel disease, megaloblastic anemia, metformin use for more than four months, neurologic symptoms, proton pump inhibitor use for more than 12 months, vegetarian/vegan.

Figure 2. Suggested approach to the patient with suspected vitamin B₁₂ deficiency.

Information from references 18 and 26.

Haematology does not recommend retesting vitamin B₁₂ levels after treatment has been initiated, and no guidelines address the optimal interval for screening high-risk patients.¹⁸

A 2005 Cochrane review involving 108 patients with vitamin B₁₂ deficiency found that high-dose oral replacement (1 mg to 2 mg per day) was as effective as parenteral administration for correcting anemia and

Table 4. Time to Improvement of Abnormalities in Vitamin B₁₂ Deficiency After Initiation of Treatment

Abnormality	Expected time until improvement
Homocysteine or methylmalonic acid level, or reticulocyte count	One week
Neurologic symptoms	Six weeks to three months
Anemia, leukopenia, mean corpuscular volume, or thrombocytopenia	Eight weeks

Information from reference 27.

SORT: KEY RECOMMENDATIONS FOR PRACTICE

Clinical recommendation	Evidence rating	References
Patients with risk factors for vitamin B ₁₂ deficiency should be screened with a complete blood count and serum vitamin B ₁₂ level.	C	18
A serum methylmalonic acid level may be used to confirm vitamin B ₁₂ deficiency when it is suspected but the serum vitamin B ₁₂ level is normal or low-normal.	C	18
Oral and injectable vitamin B ₁₂ are effective means of replacement, but injectable therapy leads to more rapid improvement and should be considered in patients with severe deficiency or severe neurologic symptoms.	B	18
Patients who have had bariatric surgery should receive 1 mg of oral vitamin B ₁₂ per day indefinitely.	C	31

A = consistent, good-quality patient-oriented evidence; B = inconsistent or limited-quality patient-oriented evidence; C = consensus, disease-oriented evidence, usual practice, expert opinion, or case series. For information about the SORT evidence rating system, go to <http://www.aafp.org/afpsort>.

neurologic symptoms.²⁸ However, oral therapy does not improve serum methylmalonic acid levels as well as intramuscular therapy, although the clinical relevance is unclear.²⁹ There is also a lack of data on the long-term benefit of oral therapy when patients do not take daily doses.² There is insufficient data to recommend other formulations of vitamin B₁₂ replacement (e.g., nasal, sublingual, subcutaneous).² The British Society for Haematology recommends intramuscular vitamin B₁₂ for severe deficiency and malabsorption syndromes, whereas oral replacement may be considered for patients with asymptomatic, mild disease with no absorption or compliance concerns.¹⁸

Prevention

Because of potential interactions from prolonged medication use, physicians should

consider screening patients for vitamin B₁₂ deficiency if they have been taking proton pump inhibitors or H₂ blockers for more than 12 months, or metformin for more than four months.⁵ The average intake of vitamin B₁₂ in the United States is 3.4 mcg per day, and the recommended dietary allowance is 2.4 mcg per day for adult men and nonpregnant women, and 2.6 mcg per day for pregnant women.³⁰ Patients older than 50 years may not be able to adequately absorb dietary vitamin B₁₂ and should consume food fortified with vitamin B₁₂.³⁰ Vegans and strict vegetarians should be counseled to consume fortified cereals or supplements to prevent deficiency. The American Society for Metabolic and Bariatric Surgery recommends that patients who have had bariatric surgery take 1 mg of oral vitamin B₁₂ per day indefinitely.³¹

Vitamin B₁₂ and Hyperhomocysteinemia

Vitamin B₁₂ deficiency is a much more common cause of hyperhomocysteinemia in developed countries than folate deficiency because of widespread fortification of food with folate. Although epidemiologic studies have shown an association between vascular disease and hyperhomocysteinemia, large randomized controlled trials have shown that lowering homocysteine levels in these patients does not reduce the number of myocardial infarctions or strokes, or improve mortality rates.³² Similarly, an association between elevated homocysteine levels and cognitive impairment has been noted, but subsequent vitamin B₁₂ replacement does not have preventive or therapeutic benefit.³³
